Is not this formula too easy to accomplish anything worthwhile? It defines no right or wrong, assigns no obligation, calls for no sacrifice, implies no change in the current philosophy of values. In respect of land use, it urges only enlightened self-interest. Just how far will such education take us? An example will perhaps yield a partial answer.

By 1930 it had become clear to all except the ecologically blind that southwestern Wisconsin's topsoil was slipping seaward. In 1933 the farmers were told that if they would adopt certain remedial practices for five years, the public would donate Civilian Conservation Corps labour to install them, plus the necessary machinery and materials. The offer was widely accepted, but the practices were widely forgotten when the five-year contract period was up. The farmers continued only those practices that yielded an immediate and visible economic gain for themselves.

This led to the idea that maybe farmers would learn more quickly if they themselves wrote the rules. Accordingly the Wisconsin Legislature in 1937 passed the Soil Conservation District Law. This said to farmers, in effect: *We, the public, will furnish you free technical service and loan you specialized machinery, if you will* *write your own rules for land use. Each county may write its own rules, and these will have the force of law*. Nearly all the counties promptly organized to accept the proffered help, but after a decade of operation, *no county has yet written a single rule*. There has been visible progress in such practices as strip-cropping, pasture renovation and soil liming, but none in fencing woodlots against grazing, and none in excluding plough and cow from steep slopes. The farmers, in short, have selected those remedial practices which were profitable anyhow, and ignored those which were profitable to the community, but not clearly profitable to themselves.

When one asks why no rules have been written, one is told that the community is not yet ready to support them; education must precede rules. But the education actually in progress makes no mention of obligations to land over and above those dictated by self-interest. The net result is that we have more education but less soil, fewer healthy woods and as many floods as in 1937.

The puzzling aspect of such situations is that the existence of obligations over and above self-interest is taken for granted in such rural community enterprises as the betterment of roads, schools, churches and baseball teams. Their existence is not taken for granted, nor as yet seriously discussed, in bettering the behaviour of the water that falls on the land, or in the preserving of the beauty or diversity of the farm landscape. Land use ethics are still governed wholly by economic self-interest, just as social ethics were a century ago.

To sum up: we asked the farmer to do what he conveniently could to save his soil, and he has done just that, and only that. The farmer who clears the woods off a 75 per cent slope, turns his cows into the clearing and dumps its rainfall, rocks, and soil into the community creek, is still (if otherwise decent) a respected member of society. If he puts lime on his fields and plants his crops on contour, he is still entitled to all the privileges and emoluments of his Soil Conservation District. The District is a beautiful piece of social machinery, but it is coughing along on two cylinders because we have been too timid, and too anxious for quick success, to tell the farmer the true magnitude of his obligations. Obligations have no meaning without conscience, and the problem we face is the extension of the social conscience from people to land.

No important change in ethics was ever accomplished without an internal change in our intellectual emphasis, loyalties, affections and convictions. The proof that conservation has not yet touched these foundations of conduct lies in the fact that philosophy and religion have not yet heard of it. In our attempt to make conservation easy, we have made it trivial.

Substitutes for a Land Ethic

When the logic of history hungers for bread and we hand out a stone, we are at pains to explain how much the stone resembles bread. I now describe some of the stones which serve in lieu of a land ethic.

One basic weakness in a conservation system based wholly on economic motives is that most members of the land community have no economic value. Wildflowers and songbirds are examples. Of the 22,000 higher plants and animals native to Wisconsin, it is doubtful whether more than 5 per cent can be sold, fed, eaten or otherwise put to economic use. Yet these creatures are members of the biotic community, and if (as I believe) its stability depends on its integrity, they are entitled to continuance.

When one of these non-economic categories is threatened, and if we happen to love it, we invent subterfuges to give it economic importance. At the beginning of the century songbirds were supposed to be disappearing. Ornithologists jumped to the rescue with some distinctly shaky evidence to the effect that insects would eat us up if birds failed to control them. The evidence had to be economic in order to be valid.

It is painful to read these circumlocutions today. We have no land ethic yet, but we have at least drawn nearer the point of admitting that birds should continue as a matter of biotic right, regardless of the presence or absence of economic advantage to us.

A parallel situation exists in respect of predatory mammals, raptorial birds and fish-eating birds. Time was when biologists somewhat overworked the evidence that these creatures preserve the health of game by killing weaklings, or that they control rodents for the farmer, or that they prey only on 'worthless' species. Here again, the evidence had to be economic in order to be valid. It is only in recent years that we hear the more honest argument that predators are members of the community, and that no special interest has the right to exterminate them for the sake of a benefit, real or fancied, to itself. Unfortunately this enlightened view is still in the talk stage. In the field the extermination of predators goes merrily on: witness the impending erasure of the timber wolf by fiat of Congress, the Conservation Bureaus and many state legislatures.

Some species of trees have been 'read out of the party' by economics-minded foresters because they grow too slowly, or have too low a sale value to pay as timber crops: white cedar, tamarack, cypress, beech and hemlock are examples. In Europe, where forestry is ecologically more advanced, the non-commercial tree species are recognized as members of the native forest community, to be preserved as such, within reason. Moreover some (like beech) have been found to have a valuable function in building up soil fertility. The interdependence of the forest and its constituent tree species, ground flora and fauna is taken for granted.

Lack of economic value is sometimes a character not only of species or groups, but of entire biotic communities: marshes, bogs, dunes and 'deserts' are examples. Our formula in such cases is to relegate their conservation to government as refuges, monuments or parks. The difficulty is that these communities are usually interspersed with more valuable private lands; the government cannot possibly own or control such scattered parcels. The net effect is that we have relegated some of them to ultimate extinction over large areas. If the private owner were ecologically minded, he would be proud to be the custodian of a reasonable proportion of such areas, which add diversity and beauty to his farm and to his community.

In some instances, the assumed lack of profit in these 'waste' areas has proved to be wrong, but only after most of them had been done away with. The present scramble to reflood muskrat marshes is a case in point.

There is a clear tendency in American conservation to relegate to government all necessary jobs that private landowners fail to perform. Government ownership, operation, subsidy or regulation is now widely prevalent in forestry, range management, soil and watershed management, park and wilderness conservation, fisheries management and migratory bird management, with more to come. Most of this growth in governmental conservation is proper and logical, some of it is inevitable. That I imply no disapproval of it is implicit in the fact that I have spent most of my life working for it. Nevertheless the question arises: What is the ultimate magnitude of the enterprise? Will the tax base carry its eventual ramifications? At what point will governmental conservation, like the mastodon, become handicapped by its own dimensions? The answer, if there is any, seems to be in a land ethic, or some other force which assigns more obligation to the private landowner.

Industrial landowners and users, especially lumbermen and stockmen, are inclined to wail long and loudly about the extension of government ownership and regulation to land, but (with notable exceptions) they show little disposition to develop the only visible alternative: the voluntary practice of conservation on their own lands.

When the private landowner is asked to perform some unprofitable act for the good of the community, he today assents only with outstretched palm. If the act costs him cash this is fair and proper, but when it costs only forethought, open-mindedness or time, the issue is at least debatable. The overwhelming growth of land use subsidies in recent years must be ascribed, in large part, to the government's own agencies for conservation education: the land bureaus, the agricultural colleges and the extension services. As far as I can detect, no ethical obligation toward land is taught in these institutions.

To sum up: a system of conservation based solely on economic self-interest is hopelessly lopsided. It tends to ignore, and thus eventually to eliminate, many elements in the land community that lack commercial value, but that are (as far as we know) essential to its healthy functioning. It assumes, falsely, I think, that the economic parts of the biotic clock will function without the uneconomic parts. It tends to relegate to government many functions eventually too large, too complex, or too widely dispersed to be performed by government.

An ethical obligation on the part of the private owner is the only visible remedy for these situations.

The Land Pyramid

An ethic to supplement and guide the economic relation to land presupposes the existence of some mental image of land as a biotic mechanism. We can be ethical only in relation to something we can see, feel, understand, love, or otherwise have faith in.

The image commonly employed in conservation education is 'the balance of nature'. For reasons too lengthy to detail here, this figure of speech fails to describe accurately what little we know about the land mechanism. A much truer image is the one employed in ecology: the biotic pyramid. I shall first sketch the pyramid as a symbol of land and later develop some of its implications in terms of land-use.

Plants absorb energy from the sun. This energy flows through a circuit called the biota, which may be represented by a pyramid consisting of layers. The bottom layer is the soil. A plant layer rests on the soil, an insect layer on the plants, a bird and rodent layer on the insects and so on up through various animal groups to the apex layer, which consists of the larger carnivores.

The species of a layer are alike not in where they came from, or in what they look like, but rather in what they eat. Each successive layer depends on those below it for food and often for other services, and each in turn furnishes food and services to those above. Proceeding upward, each successive layer decreases in numerical abundance. Thus, for every carnivore there are hundreds of his prey, thousands of their prey, millions of insects, uncountable plants. The pyramidal form of the system reflects this numerical progression from apex to base. Man shares an intermediate layer with the bears, raccoons and squirrels which eat both meat and vegetables.

The lines of dependency for food and other services are called food chains. Thus soil-oak-deer-Indian is a chain that has now been largely converted to soil-corn-cow-farmer. Each species, including ourselves, is a link in many chains. The deer eats a hundred plants other than oak, and the cow a hundred plants other than corn. Both, then, are links in a hundred chains. The pyramid is a tangle of chains so complex as to seem disorderly, yet the stability of the system proves it to be a highly organized structure. Its functioning depends on the cooperation and competition of its diverse parts.

In the beginning, the pyramid of life was low and squat; the food chains short and simple. Evolution has added layer after layer, link after link. Man is one of thousands of accretions to the height and complexity of the pyramid. Science has given us many doubts, but it has given us at least one certainty: the trend of evolution is to elaborate and diversify the biota.

Land, then, is not merely soil; it is a fountain of energy flowing through a circuit of soils, plants and animals. Food chains are the living channels which conduct energy upward; death and decay return it to the soil. The circuit is not closed; some energy is dissipated in decay, some is added by absorption from the air, some is stored in soils, peats and long-lived forests; but it is a sustained circuit, like a slowly augmented revolving fund of life. There is always a net loss by downhill wash, but this is normally small and offset by the decay of rocks. It is deposited in the ocean and, in the course of geological time, raised to form new lands and new pyramids.

The velocity and character of the upward flow of energy depend on the complex structure of the plant and animal community, much as the upward flow of sap in a tree depends on its complex cellular organization. Without this complexity, normal circulation would presumably not occur. Structure means the characteristic numbers, as well as the characteristic kinds and functions, of the component species. This interdependence between the complex structure of the land and its smooth functioning as an energy unit is one of its basic attributes.

When a change occurs in one part of the circuit, many other parts must adjust themselves to it. Change does not necessarily obstruct or divert the flow of energy; evolution is a long series of self-induced changes, the net result of which has been to elaborate the flow mechanism and to lengthen the circuit. Evolutionary changes, however, are usually slow and local. Man's invention of tools has enabled him to make changes of unprecedented violence, rapidity and scope.

One change is in the composition of floras and faunas. The larger predators are lopped off the apex of the pyramid; food chains, for the first time in history, become shorter rather than longer. Domesticated species from other lands are substituted for wild ones, and wild ones are moved to new habitats. In this worldwide pooling of faunas and floras, some species get out of bounds as pests and diseases, others are extinguished. Such effects are seldom intended or foreseen; they represent unpredicted and often untraceable readjustments in the structure. Agricultural science is largely a race between the emergence of new pests and the emergence of new techniques for their control.

Another change touches the flow of energy through plants and animals and its return to the soil. Fertility is the ability of soil to receive, store and release energy. Agriculture, by overdrafts on the soil, or by too radical a substitution of domestic for native species in the superstructure, may derange the channels of flow or deplete storage. Soils depleted of their storage, or of the organic matter which anchors it, wash away faster than they form. This is erosion.

Waters, like soil, are part of the energy circuit. Industry, by polluting waters or obstructing them with dams, may exclude the plants and animals necessary to keep energy in circulation.

Transportation brings about another basic change: the plants or animals grown in one region are now consumed and returned to the soil in another. Transportation taps the energy stored in rocks and in the air, and uses it elsewhere; thus we fertilize the garden with nitrogen gleaned by the guano birds from the fishes of seas on the other side of the Equator. Thus the formerly localized and self-contained circuits are pooled on a worldwide scale.

The process of altering the pyramid for human occupation releases stored energy, and this often gives rise, during the pioneering period, to a deceptive exuberance of plant and animal life, both wild and tame. These releases of biotic capital tend to becloud or postpone the penalties of violence.

* * *

This thumbnail sketch of land as an energy circuit conveys three basic ideas:

1 That land is not merely soil.
2 That the native plants and animals kept the energy circuit open; others may or may not.
3 That man-made changes are of a different order than evolutionary changes, and have effects more comprehensive than is intended or foreseen.

These ideas, collectively, raise two basic issues: Can the land adjust itself to the new order? Can the desired alterations be accomplished with less violence?

Biotas seem to differ in their capacity to sustain violent conversion. Western Europe, for example, carries a far different pyramid than Caesar found there. Some large animals are lost; swampy forests have become meadows or ploughland; many new plants and animals are introduced, some of which escape as pests; the remaining natives are greatly changed in distribution and abundance. Yet the soil is still there and, with the help of imported nutrients, still fertile; the waters flow normally; the new structure seems to function and to persist. There is no visible stoppage or derangement of the circuit.

Western Europe, then, has a resistant biota. Its inner processes are tough, elastic, resistant to strain. No matter how violent the alterations, the pyramid, so far, has developed some new modus vivendi which preserves its habitability for man, and for most of the other natives.

Japan seems to present another instance of radical conversion without disorganization.

Most other civilized regions, and some as yet barely touched by civilization, display various stages of disorganization, varying from initial symptoms to advanced wastage. In Asia Minor and North Africa diagnosis is confused by climatic changes, which may have been either the cause or the effect of advanced wastage. In the United States the degree of disorganization varies locally; it is worst in the Southwest, the Ozarks and parts of the South, and least in New England and the Northwest. Better land uses may still arrest it in the less advanced regions. In parts of Mexico, South America, South Africa and Australia a violent and accelerating wastage is in progress, but I cannot assess the prospects.

This almost worldwide display of disorganization in the land seems to be similar to disease in an animal, except that it never culminates in complete disorganization or death. The land recovers, but at some reduced level of complexity, and with a reduced carrying capacity for people, plants and animals. Many biotas currently regarded as 'lands of opportunity' are in fact already subsisting on exploitative agriculture, i.e. they have already exceeded their sustained carrying capacity. Most of South America is overpopulated in this sense.

In arid regions we attempt to offset the process of wastage by reclamation, but it is only too evident that the prospective longevity of reclamation projects is often short. In our own West, the best of them may not last a century.

The combined evidence of history and ecology seems to support one general deduction: the less violent the man-made changes, the greater the probability of successful readjustment in the pyramid. Violence, in turn, varies with human population density; a dense population requires a more violent conversion. In this respect, North America has a better chance for permanence than Europe, if she can contrive to limit her density.

This deduction runs counter to our current philosophy, which assumes that because a small increase in density enriched human life, that an indefinite increase will enrich it indefinitely. Ecology knows of no density relationship that holds for indefinitely wide limits. All gains from density are subject to a law of diminishing returns.

Whatever may be the equation for men and land, it is improbable that we as yet know all its terms. Recent discoveries in mineral and vitamin nutrition reveal unsuspected dependencies in the up-circuit: incredibly minute quantities of certain substances determine the value of soils to plants, of plants to animals. What of the down-circuit? What of the vanishing species, the preservation of which we now regard as an aesthetic luxury? They helped build the soil; in what unsuspected ways may they be essential to its maintenance? Professor Weaver proposes that we use prairie flowers to reflocculate the wasting soils of the dust bowl; who knows for what purpose cranes and condors, otters and grizzlies may some day be used?

Land Health and the A-B Cleavage

A land ethic, then, reflects the existence of an ecological conscience, and this in turn reflects a conviction of individual responsibility for the health of the land. Health is the capacity of the land for self-renewal. Conservation is our effort to understand and preserve this capacity.

Conservationists are notorious for their dissensions. Superficially these seem to add up to mere confusion, but a more careful scrutiny reveals a single plane of cleavage common to many specialized fields. In each field one group (A) regards the land as soil, and its function as commodity-production; another group (B) regards the land as a biota, and its function as something broader. How much broader is admittedly in a state of doubt and confusion.

In my own field, forestry, Group A is quite content to grow trees like cabbages, with cellulose as the basic forest commodity. It feels no inhibition against violence; its ideology is agronomic. Group B, on the other hand, sees forestry as fundamentally different from agronomy because it employs natural species, and manages a natural environment rather than creating an artificial one. Group B prefers natural reproduction on principle. It worries on biotic as well as economic grounds about the loss of species like chestnut and the threatened loss of the white pines. It worries about a whole series of secondary forest functions: wildlife, recreation, watersheds, wilderness areas. To my mind, Group B feels the stirrings of an ecological conscience.

In the wildlife field, a parallel cleavage exists. For Group A the basic commodities are sport and meat; the yardsticks of production are ciphers of take in pheasants and trout. Artificial propagation is acceptable as a permanent as well as a temporary recourse – if its unit costs permit. Group B, on the other hand, worries about a whole series of biotic side issues. What is the cost in predators of producing a game crop? Should we have further recourse to exotics? How can management restore the shrinking species, like prairie grouse, already hopeless as shootable game? How can management restore the threatened ratites, like trumpeter swan and whooping crane? Can management principles be extended to wildflowers? Here again it is clear to me that we have the same A-B cleavage as in forestry.

In the larger field of agriculture I am less competent to speak, but there seem to be somewhat parallel cleavages. Scientific agriculture was actively developing before ecology was born, hence a slower penetration of ecological concepts might be expected. Moreover the farmer, by the very nature of his techniques, must modify the biota more radically than the forester or the wildlife manager. Nevertheless, there are many discontents in agriculture which seem to add up to a new vision of 'biotic farming'.

Perhaps the most important of these is the new evidence that poundage or tonnage is no measure of the food-value of farm crops; the products of fertile soil may be qualitatively as well as quantitatively superior. We can bolster poundage from depleted soils by pouring on imported fertility, but we are not necessarily bolstering food-value. The possible ultimate ramifications of this idea are so immense that I must leave their exposition to abler pens.

The discontent that labels itself 'organic farming', while bearing some of the earmarks of a cult, is nevertheless biotic in its direction, particularly in its insistence on the importance of soil flora and fauna.

The ecological fundamentals of agriculture are just as poorly known to the public as in other fields of land use. For example, few educated people realize that the marvellous advances in technique made during recent decades are improvements in the pump, rather than the well. Acre for acre, they have barely sufficed to offset the sinking level of fertility.

In all of these cleavages, we see repeated the same basic paradoxes: man the conqueror versus man the biotic citizen; science the sharpener of his sword versus science the searchlight on his universe; land the slave and servant versus land the collective organism. Robinson's injunction to Tristram may well be applied, at this juncture, to *Homo sapiens* as a species in geological time:

> Whether you will or not
> You are a King, Tristram, for you are one
> Of the time-tested few that leave the world,
> When they are gone, not the same place it was.
> Mark what you leave.

The Outlook

It is inconceivable to me that an ethical relation to land can exist without love, respect and admiration for land, and a high regard for its value. By value, I of course mean something far broader than mere economic value; I mean value in the philosophical sense.

Perhaps the most serious obstacle impeding the evolution of a land ethic is the fact that our educational and economic system is headed away from, rather than towards, an intense consciousness of land. Your true modern is separated from the land by many middlemen, and by innumerable physical gadgets. He has no vital relation to it; to him it is the space between cities on which crops grow. Turn him loose for a day on the land, and if the spot does not happen to be a golf links or a 'scenic' area, he is bored stiff. If crops could be raised by hydroponics instead of farming, it would suit him very well. Synthetic substitutes for wood, leather, wool and other natural land products suit him better than the originals. In short, land is something he has 'outgrown'.

Almost equally serious as an obstacle to a land ethic is the attitude of the farmer for whom the land is still an adversary, or a taskmaster that keeps him in slavery. Theoretically, the mechanization of farming ought to cut the farmer's chains, but whether it really does is debatable.

One of the requisites for an ecological comprehension of land is an understanding of ecology, and this is by no means co-extensive with 'education'; in fact, much higher education seems deliberately to avoid ecological concepts. An understanding of ecology does not necessarily originate in courses bearing ecological labels; it is quite as likely to be labelled geography, botany, agronomy, history or economics. This is as it should be, but whatever the label, ecological training is scarce.

The case for a land ethic would appear hopeless but for the minority which is in obvious revolt against these 'modern' trends.

The 'key-log' which must be moved to release the evolutionary process for an ethic is simply this: quit thinking about decent land use as solely an economic problem. Examine each question in terms of what is ethically and aesthetically right, as well as what is economically expedient. A thing is right when it tends to preserve the integrity, stability and beauty of the biotic community. It is wrong when it tends otherwise.

It of course goes without saying that economic feasibility limits the tether of what can or cannot be done for land. It always has and it always will. The fallacy the economic determinists have tied around our collective neck, and which we now need to cast off, is the belief that economics determines *all* land use. This is simply not true. An innumerable host of actions and attitudes, comprising perhaps the bulk of all land relations, is determined by the land users' tastes and predilections, rather than by his purse. The bulk of all land relations hinges on investments of time, forethought, skill and faith rather than on investments of cash. As a land user thinketh, so is he.

I have purposely presented the land ethic as a product of social evolution because nothing so important as an ethic is ever 'written'. Only the most superficial student of history supposes that Moses 'wrote' the Decalogue; it evolved in the minds of a thinking community, and Moses wrote a tentative summary of it for a 'seminar'. I say tentative because evolution never stops.

The evolution of a land ethic is an intellectual as well as emotional process. Conservation is paved with good intentions which prove to be futile, or even dangerous, because they are devoid of critical understanding either of the land, or of economic land use. I think it is a truism that as the ethical frontier advances from the individual to the community, its intellectual content increases.

The mechanism of operation is the same for any ethic: social approbation for right actions: social disapproval for wrong actions.

By and large, our present problem is one of attitudes and implements. We are remodelling the Alhambra with a steam-shovel, and we are proud of our yardage. We shall hardly relinquish the shovel, which after all has many good points, but we are in need of gentler and more objective criteria for its successful use.

2

Four Principles of Natural Farming

Masanobu Fukuoka

Make your way carefully through these fields. Dragonflies and moths fly up in a flurry. Honeybees buzz from blossom to blossom. Part the leaves and you will see insects, spiders, frogs, lizards and many other small animals bustling about in the cool shade. Moles and earthworms burrow beneath the surface.

This is a balanced rice field ecosystem. Insect and plant communities maintain a stable relationship here. It is not uncommon for a plant disease to sweep through this area, leaving the crops in these fields unaffected.

And now look over at the neighbour's field for a moment. The weeds have all been wiped out by herbicides and cultivation. The soil animals and insects have been exterminated by poison. The soil has been burned clean of organic matter and microorganisms by chemical fertilizers. In the summer you see farmers at work in the fields, wearing gas masks and long rubber gloves. These rice fields, which have been farmed continuously for over 1500 years, have now been laid waste by the exploitive farming practices of a single generation.

Four Principles

The first is no cultivation, that is, no ploughing or turning of the soil. For centuries, farmers have assumed that the plough is essential for growing crops. However, non-cultivation is fundamental to natural farming. The Earth cultivates itself naturally by means of the penetration of plant roots and the activity of microorganisms, small animals and earthworms.

The second is no chemical fertilizer or prepared compost.[1] People interfere with nature, and, try as they may, they cannot heal the resulting wounds. Their careless farming practices drain the soil of essential nutrients and the result is yearly depletion of the land. If left to itself, the soil maintains its fertility naturally, in accordance with the orderly cycle of plant and animal life.

Reprinted from Masanobu Fukuoka. 1978. *One Straw Revolution: Four Principles of Natural Farming.* Other India Press and Rodale Press.

The third is no weeding by tillage or herbicides. Weeds play their part in building soil fertility and in balancing the biological community. As a fundamental principle, weeds should be controlled, not eliminated. Straw mulch, a ground cover of white clover interplanted with the crops, and temporary flooding provide effective weed control in my fields.

The fourth is no dependence on chemicals.[2] From the time that weak plants developed as a result of such unnatural practices as plowing and fertilizing, disease and insect imbalance became a great problem in agriculture. Nature, left alone, is in perfect balance. Harmful insects and plant diseases are always present, but do not occur in nature to an extent which requires the use of poisonous chemicals. The sensible approach to disease and insect control is to grow sturdy crops in a healthy environment.

Cultivation

When the soil is cultivated the natural environment is altered beyond recognition. The repercussions of such acts have caused the farmer nightmares for countless generations. For example, when a natural area is brought under the plough very strong weeds such as crabgrass and docks sometimes come to dominate the vegetation. When these weeds take hold, the farmer is faced with a nearly impossible task of weeding each year. Very often, the land is abandoned.

In coping with problems such as these, the only sensible approach is to discontinue the unnatural practices which have brought about the situation in the first place. The farmer also has a responsibility to repair the damage he has caused. Cultivation of the soil should be discontinued. If gentle measures such as spreading straw and sowing clover are practiced, instead of using man-made chemicals and machinery to wage a war of annihilation, then the environment will move back towards its natural balance and even troublesome weeds can be brought under control.

Fertilizer

I have been known, in chatting with soil-fertility experts, to ask, ‘If a field is left to itself, will the soil's fertility increase or will it become depleted?’ They usually pause and say something like, ‘Well, let's see… It'll become depleted. No, not when you remember that when rice is grown for a long time in the same field without fertilizer, the harvest settles at about 9 bushels (525 pounds) per quarter acre. The earth would become neither enriched nor depleted.’

These specialists are referring to a cultivated, flooded field. If nature is left to itself, fertility increases. Organic remains of plants and animals accumulate and are decomposed on the surface by bacteria and fungi. With the movement of rainwater, the nutrients are taken deep into the soil to become food for microorganisms, earthworms and other small animals. Plant roots reach to the lower soil strata and draw the nutrients back up to the surface.

If you want to get an idea of the natural fertility of the earth, take a walk to the wild mountainside sometime and look at the giant trees that grow without fertilizer and without cultivation. The fertility of nature, as it is, is beyond reach of the imagination.

Cut down the natural forest cover, plant Japanese red pine or cedar trees for a few generations, and the soil will become depleted and open to erosion. On the other hand, take a barren mountain with poor, red clay soil and plant pine or cedar with a ground cover of clover and alfalfa. As the green manure[3] enriches and softens the soil, weeds and bushes grow up below the trees, and a rich cycle of regeneration is begun. There are instances in which the top four inches of soil have become enriched in less than ten years.

For growing agricultural crops, also, the use of prepared fertilizer can be discontinued. For the most part, a permanent green manure cover and the return of all the straw and chaff to the soil will be sufficient. To provide animal manure to help decompose the straw, I used to let ducks loose in the fields. If they are introduced as ducklings while the seedlings are still young, the ducks will grow up together with the rice. Ten ducks will supply all the manure necessary for a quarter acre and will also help to control the weeds.

I did this for many years until the construction of a national highway made it impossible for the ducks to get across the road and back to the coop. Now I use a little chicken manure to help decompose the straw. In other areas ducks or other small grazing animals are still a practical possibility.

Adding too much fertilizer can lead to problems. One year, right after the rice transplanting, I contracted to rent 1¼ acres of freshly planted rice fields for a period of one year. I ran all the water out of the fields and proceeded without chemical fertilizer, applying only a small amount of chicken manure. Four of the fields developed normally. But in the fifth, no matter what I did, the rice plants came up too thickly and were attacked by blast disease. When I asked the owner about this, he said he had used the field over the winter as a dump for chicken manure.

Using straw, green manure and a little poultry manure, one can get high yields without adding compost or commercial fertilizer at all. For several decades now, I have been sitting back, observing nature's method of cultivation and fertilization. And while watching, I have been reaping bumper crops of vegetables, citrus, rice and winter grain as a gift, so to speak, from the natural fertility of the earth.

Coping with Weeds

Here are some key points to remember in dealing with weeds: As soon as cultivation is discontinued, the number of weeds decreases sharply. Also, the varieties of weeds in a given field will change.

If seeds are sown while the preceding crop is still ripening in the field, those seeds will germinate ahead of the weeds. Winter weeds sprout only after the rice has been harvested, but by that time the winter grain already has a head start. Summer weeds sprout right after the harvest of barley and rye, but the rice is already growing strongly. Timing the seeding in such a way that there is no interval between succeeding crops gives the grain a great advantage over the weeds.

Directly after the harvest, if the whole field is covered with straw, the germination of weeds is stopped short. White clover sowed with the grain as a ground cover also helps to keep weeds under control.

The usual way to deal with weeds is to cultivate the soil. But when you cultivate, seeds lying deep in the soil, which would never have germinated otherwise, are stirred up and given a chance to sprout. Furthermore, the quick-sprouting, fast-growing varieties are given the advantage under these conditions. So you might say that the farmer who tries to control weeds by cultivating the soil is, quite literally, sowing the seeds of his own misfortune.

'Pest' Control

Let us say that there are still some people who think that if chemicals are not used their fruit trees and field crops will wither before their very eyes. The fact of the matter is that by *using* these chemicals, people have unwittingly brought about the conditions in which this unfounded fear may become reality.

Recently Japanese red pines have been suffering severe damage from an outbreak of pine bark weevils. Foresters are now using helicopters in an attempt to stop the damage by aerial spraying. I do not deny that this is effective in the short run, but I know there must be another way.

Weevil blights, according to the latest research, are not a direct infestation, but follow upon the action of mediating nematodes. The nematodes breed within the trunk, block the transport of water and nutrients, and eventually cause the pine to wither and die. The ultimate cause, of course, is not yet clearly understood.

Nematodes feed on a fungus within the tree's trunk. Why did this fungus begin to spread so prolifically within the tree? Did the fungus begin to multiply after the nematode had already appeared? Or did the nematode appear because the fungus was already present? It boils down to a question of which came first, the fungus or the nematode?

Furthermore, there is another microbe about which very little is known, which always accompanies the fungus, and a virus toxic to the fungus. Effect following effect in every direction, the only thing that can be said with certainty is that the pine trees are withering in unusual numbers.

People cannot know what the true cause of the pine blight is, nor can they know the ultimate consequences of their 'remedy'. If the situation is meddled with unknowingly, that only sows the seeds for the next great catastrophe. No, I cannot rejoice in the knowledge that immediate damage from the weevil has been reduced by chemical spraying. Using agricultural chemicals is the most inept way to deal with problems such as these, and will only lead to greater problems in the future.

These four principles of natural farming (no cultivation, no chemical fertilizer or prepared compost, no weeding by tillage or herbicides and no dependence on chemicals) comply with the natural order and lead to the replenishment of nature's richness. All my fumblings have run along this line of thought. It is the heart of my method of growing vegetables, grain and citrus.

Notes

1 For fertilizer Mr Fukuoka grows a leguminous ground cover of white clover, returns the threshed straw to the fields, and adds a little poultry manure.

2 Mr Fukuoka grows his grain crops without chemicals of any kind. On some orchard trees he occasionally uses a machine oil emulsion for the control of insect scales. He uses no persistent or broad-spectrum poisons, and has no pesticide 'programme'.

3 Ground cover crops such as clover, vetch and alfalfa which condition and nourish the soil.

3

Knowing Systems and the Environment

Richard Bawden

Introduction

The logic behind the 'environmental concern' is seemingly impeccable, and evidence in its support, increasingly irrefutable. Through our activities as an ever-expanding and ubiquitous population of human beings, we are despoiling and degrading the environment of the world about us, while depleting it of its finite resources at an ever-increasing rate. This is not only threatening our own well-being and that of future generations of our own species, but also the stability and sustainability of particular biotic communities across the planet, as well as the integrity of the biosphere as a whole. The organization, functions and hierarchical organization of the long-evolved 'natural ecosystems' in which we are embedded as but one component species, are all now at very considerable risk. Such could be the level of the malignancy here that it could lead to a loss of hierarchical control across the entire 'systems-of-complex systems' by which 'nature' is seemingly organized, with the prospect of 'sudden and catastrophic failure' (Pattee, 1973) on an unimaginable scale. Ironically and tragically, much of this circumstance represents the unintended consequences of the developmental processes of modernization that we had come to claim as our greatest achievement as a species. This should dictate the need for a critical reappraisal of our whole techno-scientific, neoliberal approach to the idea of progress and 'betterment' and for us to be much more reflexive about how we should be living our lives in the context of the impacts that we are having on our environment (Beck, 1992).

The Conundrum

In the face of such a comprehensive and urgent challenge, it is difficult to reconcile our continuing acts of environmental despoliation with our competencies and dispositions as both rational beings and as the 'moral animals' that we claim to be (Wright, 1994). If we know that what we are doing is unsustainable in the long run, and that we ought not to be doing what we are doing, then why do we continue doing it? If, in all conscience, we appreciate that it is somehow ethically 'wrong' to behave in a manner that threatens the 'integrity, stability and beauty of the biotic community', as Leopold (1949) would assert, then why do we fail to heed our conscience and behave otherwise? And perhaps most significantly and irrationally of all, why, as knowledgeable and concerned citizens of the world, are we continuing to ignore the sensible call to 'learn our way out' of the mess that we ourselves are creating (Milbraith, 1989)?

The focus on learning here – on coming to know – is salutary: rather than planning our way forward under circumstances where, as convention has had it, we were confident of the end-state that we sought, we can only learn our way towards the adaptive management of the resilient systems that are key to sustainable futures (Holling and Gunderson, 2002). The very notion of what it is that we consider most worthy of being sustained in our lives, is, and will probably forever remain after all, quintessentially contestable (Davison, 2001). In essence, our quest to come to terms with sustainability and to design modes of development that lead to environmental sustainability must start with learning what each other means when we use those terms. As it is we, the citizenry, who are responsible for the mess that we now perceive we are making of the world about us, so it is up to us collectively to make-meaning through our learning as the basis for our collective judgements about what we now need to do. In other words, it is to social forms of learning that we need to now turn to inform the way by which, acting together, we should manage our environments within the context of sustainable futures (Keen et al, 2005). Social learning is central to the processes of the adaptive management (Holling, 1978) which we need to employ in order to reduce both uncertainties regarding matters of fact and disagreements about goals, objectives and values that can all affect management decisions with respect to the search for sustainability (Norton, 2005). A key complication here is that *what* each individual comes to know, through learning, is very much a function of *how* he or she comes to know, and this makes the search for communal meaning and thus consensual judgment singularly difficult (Maturana and Varela, 1987). And this is then further compounded by the communication limitations imposed by language (Norton, 2005) and even more fundamentally by the apparent 'taboo' of Western culture that 'tells us it is forbidden to know about knowing' (Maturana and Varela, 1987).

While it is our reluctance and/or our lack of capability to engage in social learning or even to recognize its significance that arguably pose the greatest impediments to our current dilemma, other factors also clearly contribute.

There is, for instance, the issue of the priorities that we set for ourselves, to say nothing of our denial of the circumstances on the one hand, and of our addiction to our current ways of life and the resources that we need to support these, on the other (Griffiths, 2003). It is indeed as difficult to concentrate on the global greenhouse gas emissions when one is trying to keep warm in a North American winter or has to drive to the shops in the mall or to the school in the suburbs or to church on the Sabbath, as it is to be concerned with the integrity of the proverbial swamp under the duress of fighting off the equally proverbial alligators. As the human population moves inexorably towards the ten billion mark, and upwards, it is sufficiently difficult to see how the quest for ever-increasing production of food can be sustained for instance, or how the growing demand for energy resources can be met in a rapidly 'globalizing' and modernizing world, without also having to worry about sustaining the environment writ large into an indeterminate future.

We are also victims of the priorities that are set for us by others who have their own motives and motivations for so doing, be that short-term economic gain or political expedience or the machinations of the cultural politics in which environmental discourse is now conducted (Hajer, 1996).

Then there is the matter of the abdication, by us as a civil society, of our responsibilities for public judgement through our deferment, in decisions regarding the public good (Giddens, 1979), to the expertise of the scientists, economists and the policy makers, and to the officers and institutions of governance. After all, a perfectly rational defence for this can be raised with respect to what Fuller (1991) refers to as 'cognitive authoritarianism' where the rationality of thinking for oneself 'diminishes as the knowledge-gathering activities of society expand to the point of requiring the division of cognitive labour into autonomous expertises'. The clear downsides of this phenomenon, however, relate both to the eventual loss of the capacity of humans to participate in any discussions and decisions about the ways by which we should live our lives through sheer lack of practice (Yankelovich, 1991) and to the essential hegemony that an instrumental technical rationality has come to assume over other rationalities, especially in 'developed' capitalist societies where questions of 'how' have come to supersede those of 'why' (Habermas, 1979). These two latter positions echo the equally somber view of Toffler (1984) that the 'political technology' that has emerged along with modernization has not been particularly adaptive, leading instead to 'a mismatch between our decisional technology and the decisional environment' that has been characterized by 'a cacophonous confusion, countless self-canceling decisions, noise, fury, and gross ineptitude'. Under these circumstances it is difficult to disagree with Dietz and his colleagues that devising ways to 'sustain the earth's ability to support diverse life, including a reasonable quality of life for humans, involves making tough decisions under uncertainty, complexity, and substantial biophysical constraints as well as conflicting human values and interests' (Dietz et al, 2003).

It is this claim that provides a clue to perhaps the most significant answer to questions about our seeming lack of commitment to 'learning our way out' of the enduring, self-inflicted crisis of our relationships with the world about us. While environmental scientists, systems ecologists, social ecologists, economists, sociologists and other 'experts' have indeed come to know a very significant amount about 'natural' and 'social systems' 'out there', as a civil society we still know very little about how we can collectively come to make knowledgeable decisions and judgements about what we need to do to change the way we live our everyday lives. In focusing so attentively on knowing *systems* 'out there' we scientists have come to ignore the nature, significance and development of the *knowing* systems by which they can become known to us all and can be collectively and sustainably managed. We have also managed to alienate a significant proportion of our fellow citizens through their perceptions of the epistemic limitations of our own learning systems (though they would probably not phrase it exactly in those terms) and our unwillingness to either appreciate or to accommodate other systems of knowing (Leach et al, 2005).

The introduction of the idea of 'system' here is deliberate and timely, for the systems idea will be the cognitive principle around which the arguments that follow, will be organized.

The Systems Idea

It is difficult these days to browse any article or book about the science, management or politics of the environment that is free of any explicit reference to 'systems' or 'systemics' or, at least, implicit embrace of 'holism' as an essential perspective. These range in their scale of reference from expositions of the panarchy theory of *ecosystem* organization (Gunderson and Holling, 2002) through the significance of *knowledge systems* for sustainable development (Cash et al, 2003) to the characteristics of emerging sciences themselves as with *systems* ecology and, most recently perhaps, in *systems biology* (Kitano, 2002). The ideas that unite these disparate endeavours include wholeness, comprehensiveness, interconnectedness, embeddedness and emergence.

In this manner, environmental science well exemplifies the claim of Ackoff (1974) that 'the systems age' has come to replace 'the machine age' of the industrial revolution, with holism coming to challenge the previously dominant epistemologies of 'reductionism' and 'positivism' of pre-systemic science. As Jackson (2000) has argued, this new-age dawning is a response to the 'complexity and turbulence' that we are all experiencing in our everyday lives, as well as by the additional confusion brought by the 'multiplicity of viewpoints about the direction we should be taking' and by the multitude of concerns about how we should be handling the difficulties that we face. The adoption of systems (= systemic) perspectives allows a cognitive coherence to be brought to bear on our considerations of these circumstances.

All acts of cognition start with a distinction between a thing (or a being or an entity) and its background or its environment, and each time we explicitly refer to anything, therefore we specify 'a criterion of distinction' which indicates what we are talking about (Maturana and Varela, 1987). Cognition thus depends on our abilities to distinguish between an 'it' and the 'other'. In its simplest formulation then, the systems idea makes the distinction between the system as a coherent bounded entity (the 'it') and the environment (the 'other') from which it can be distinguished, but with which is structurally coupled through recurrent interactions between the two (Maturana and Varela, 1987). Therefore the unit of interest of the systemist – where systemists are to systems as economists are to economies – is both the 'it' and the 'other' as well as the relationships between the two. In fact, systemists typically think in three 'it/other' dimensions – the part (subsystem), the whole (the system of interest), and the higher order whole (the environmental supra-system of the system) of which the system is itself a subsystem – plus all the sets of interactions within and between these three levels. The significance of this 'tri-hierarchical' or 'holarchical' conceptual organization of systems-of-systems lies with the belief that at each 'level', surprisingly novel properties, that are unique to that level, emerge as a function of the interrelationships between its component subsystems and the environment that its higher order system presents to them. The fundamental assumption of 'holism' therefore, is that no system can be known, nor its total characteristics nor properties predicted, through a study of any of its component subsystems in isolation from each other or from the system itself: an assumption that is in direct opposition to the basic premise of reductionism.

The systems idea is far from new within the natural sciences of course. Indeed while an appreciation of the significance of what might be termed an 'essence of wholeness' seems to pervade a wide range of 'indigenous cultures' and can be associated with an intellectual heritage from ancient Greece, most especially through the insights of Aristotle (Russell, 1961), some of the earliest formalizations of thinking in 'systems terms' can be found among scientists writing about biological phenomena and the 'nature of nature'. Smuts (1926), for instance, was the first to formally write about 'holism' – which he defined as 'the tendency in nature to produce wholes' – and of the significance of that to 'the internal organization' of organisms and to the evolution of their species. In the same era, Woodger (1929) further extended these ideas through his emphasis on the hierarchical nature of organization within organisms, while both Canon (1932) and Henderson (1941) reflected on the significance of the capacities of organisms as 'living systems' to adapt in order to maintain their own integrity in the face of challenges from the turbulent environments in which they had to exist.

Perhaps the most influential biologist with respect to the application of the systems idea to biology, however, was von Bertalanffy who took some of the key concepts of these early pioneers and further extended them into the formulation of what he eventually referred to as a General Systems Theory (GST) (von Bertalanffy, 1968). Earlier, he had made the vital distinction between 'closed' and 'open' systems (von Bertalanffy, 1950) with regard to their respective relationships with their environments. Central features of the 'open systems' of von Bertalanffy included the need for 'cybernetic regulative processes' that were essential for maintaining their 'steady state equilibria'. Tellingly, the concept of the 'ecosystem', as it was introduced by Tansley (1935), was a much looser notion of a 'living system' than that developed by von Bertalanffy and his 'systems' predecessors, referring, as it did, to a relatively unbounded set of structural and functional relationships between a biotic community and some circumscribed abiotic features. The integrity of such a system was held to be maintained in a state of equilibrium through the flows of energy and matter between its parts. This key focus on the structural and functional nature of ecosystems in equilibrium was later replaced by the more cybernetic notions of dynamic equilibria and steady states (Patten, 1959) in which a much clearer distinction was made between the ecosystem and its environment. Other vital concepts that this view of functional organizational integrity permitted was the possibility of the adaptation of the whole ecosystem with respect to changes in its environment as well as its evolution as a whole entity as a function of changes in the diversity both of its parts and of the pattern of interrelationships between them. Thus while it became possible to talk sensibly of both stability and resilience of ecosystems as prerequisite properties for adaptation in turbulent environments (Holling, 1973), it also made sense to talk of their capacity to evolve as whole, integrated entities, even in the absence of any clear empirical evidence that this indeed did occur in actuality.

While having adaptive capabilities of this type, such self-organizing systems are generally regarded as being very complex in their organization and in the spectrum of their interrelationships with the environments in which they are embedded and with which they interact. They can be so complex and dynamic in fact, that they can 'move' or be forced to positions that are far from equilibrium (Gleik, 1987), in which state they are regarded as being on the 'edge of chaos' where a small change in one component of the system can result in greatly amplified reactions elsewhere in the system. This can lead either to the demise of such systems or to the emergence of totally different systems (Stacey, 1996). Of even greater significance in this context, is the possibility, promoted by hierarchy and panarchy theorists, that entire hierarchies of systems can be affected under conditions where the complexity of any system within them becomes so great that it overwhelms existing controls across the entire hierarchy (Levins, 1973) with potentially disastrous results. Importantly it has been claimed that these 'natural' phenomena have potentially as much significance to hierarchies of human organizations and 'social systems' as they do for the ecosystems and hierarchies of nature (Wheatley, 1992). Indeed it was an economist who was to add considerable rigour to GST with his conceptualization of a nine-level hierarchical typology of complexity (Boulding, 1956), that ranged from static structures and frameworks that can be studied, through to transcendental systems which are the realm of 'inescapable unknowables'. Boulding's other considerable contribution was to argue that GST could be used for ordering different fields of study through a focus on the 'individual unit of behavior' in addition to its aim of developing a theory of very general principles, which, as Jackson (2000) observes, was the primary concern of von Bertalanffy.

The key feature of a general systems theory which allows this submission is the principle of isomorphism from which many have been able to conclude that what is so for 'natural systems' must be equally so for 'social systems'. And thus all that has been written above with regard to the nature and behavioral characteristics of living systems has been transposed in one form or another over the years, to apply to the nature and dynamics of human organizations and societies: these are, as the logic goes, composed of human beings which are, in turn, 'living systems' and much effort has been put into the application of systems approaches to human affairs over many decades past, in the search for knowledge about the nature of 'human systems'. This has a particular relevance to this present context of an environmental challenge that dictates the need to come to know and understand what is claimed to be 'the fundamental character of interactions between nature and society' (Kates et al, 2001). This is a challenge that accepts that the governance of ecosystems as complex adaptive systems requires flexibility and cognitive capacities for knowing and learning in response to 'environmental feedback' (Levin, 1998).

For all of these efforts, however, and for all of the apparent success of the system's focus in ecology, in environmental science and as a feature of the emerging sustainability sciences (Kates et al, 2001) and systems biology (Kitano, 2002), the systems idea and the styles of systems thinking that it promotes, has actually found declining support within the social sciences. As one of its most astute observers posits, systems thinking was in a less secure position within the social sciences at the beginning of the 21st century, than it had occupied several decades earlier (Jackson, 2000) at the time that the 'dawn of the systems age' had been acclaimed by Ackoff (1974). This represented a significant change from the situation where systems perspectives on, and systems approaches to the analysis of, social groupings had really been the dominant paradigm within sociology at least, and most especially among those concerned with organizational management and development.

While host of reasons can be cited for this situation – and Jackson (2000) indeed articulates most of the major influences, from the novelty of changing paradigmatic perspectives that range from functionalist through interpretivist and emancipatory to postmodernist – a central distinction between 'natural systems' and their 'social system' analogues is the inherent reflexivity of human beings (Westley et al, 2002) and our critical capacities for knowing, and for changing our minds and the views that we hold of the world about us.

As it happens, Ackoff would have been more accurate to have claimed in the mid-1970s that this was the dawning of a 'new systems age', or the emergence of a 'second wave of systems thinking', as Midgely (2000) describes it, which was being characterized by a very significant change of mind about 'systems' themselves and systemics, among, at least some, systemists. And this observation provides a useful segue into the next section of this chapter where the focus changes from a consideration of 'systems in the world' to the 'systems of cognition' through which we come to know that world. In essence, in now changing the emphasis from knowing *systems* as it were, to *knowing* systems, we reflect what Checkland (1981) referred to with his introduction of the soft systems methodology as 'the shift in systemicity from the world to ways of inquiry into that world' which indeed represented the character of the dawning of the 'new systems age' to which he himself has been such a dominant contributor.

Knowing Systems

A useful way of exploring the notion, nature, development and significance of 'knowing systems' is to reprise the earlier concept of three-dimensional thinking, specifically through the introduction and exploration of the three-level model of cognitive processing developed by Kitchener (1983) in which she suggested that different 'levels of processing' allow individuals to monitor one level of cognitive tasks at another level. She distinguishes between cognition (or level one), meta-cognition (level two) and epistemic cognition (level three) as a hierarchical sequence through which individuals can monitor the way by which they conduct their own basic cognitive tasks through a meta-cognitive process, which is itself monitored by a process of epistemic cognition. Applying a system's logic to this model, and expressing it in terms of knowing, it is thus possible to claim that a knowing or learning system can be seen to intrinsically comprise: (i) a cognitive (sub)system, which deals with the process of coming to know about the matter to hand; (ii) a meta-cognitive system that deals with the process by which the matter to hand is, and can be known; and (iii) the epistemic-cognitive (supra-)system that deals with the epistemological limits to what can be known about the other two levels as circumscribed by the very nature of knowledge itself. Conceived in this manner, each level in this intrinsic 'system-of-systems' is profoundly interconnected with the others, with each essentially providing the contextual environment for the others. The epistemic supra-system, furthermore, can be expanded to embrace not just epistemological aspects of knowing and knowledge, but also of ontological assumptions about reality and the nature of being, and about axiological assumptions and beliefs that are expressed as values. In this manner, the essential focus of the epistemic (supra-)system are the cognitive frameworks or 'meaning perspectives' or *Weltanschauungen* that represent 'those usually taken-for-granted and often idiosyncratic values, norms, and beliefs that constitute our individual and socialized views of the world' (Plas, 1986). As Kuhn (1962) presented them, such worldviews become paradigms when, as 'entire constellations of beliefs, values, techniques and so on' they are shared and put into practice by given communities. And this emphasis on 'practice' adds the fourth element of 'methodology' to the episteme where it represents the way through which the other three are interpreted into action. Thus where method, as the process of knowing, is the focus of meta-cognitive inquiry and evaluation, then methodology, as the expression of epistemological, ontological and axiological assumptions in practice, is the focus for epistemic-cognitive inquiry.

From this perspective then, it is entirely appropriate to claim that the emergence of the 'second wave of systems thinking' and the introduction of profound distinctions between the previous 'hard' systems thinkers and the new 'soft' systems types was indeed equivalent to the introduction of a new paradigm of systemics. In this light, it is perfectly understandable, as Kuhn himself would have predicted, that the shift would be associated with very significant controversy equivalent to an 'open intellectual warfare' which not only regrettably continues to this day, but has been further compounded by the subsequent introduction of a third 'critical' wave (Midgley, 2000) which focuses attention essentially on to judgements to do with social (and environmental) conditions, with the placement of boundaries and with reflexivity in knowing. These three 'waves' differ very profoundly from each other in their epistemic assumptions about the nature of nature, the nature of knowledge and the nature of human nature. Ideas from all three waves or schools of systems thinking will be significant in the conceptualization of the critical knowing/learning systems with which this chapter concludes.

The epistemic position adopted by the General Systems Theorists and by a generation of systems practitioners who were significantly influenced by them (including many systems ecologists, simulation modellers, ecosystem and systems biologists, and environmental scientists), was of the 'hard school'. From this dualistic perspective, nature 'really' is organized in the form of coherent 'systems' of integrated parts that, in turn, 'really' are organized as nested system hierarchies. In this regard it is also interesting to note the definition of a human community offered by Flora et al (1992) as 'a place and *a human system*', the claim by Daley and Netting (1994) that 'communities are living entities … (that) … like people, go through a normal life cycle', and their call for 'understanding complex social systems' as a vital reason for introducing 'systems thinking' into community development (Daley and Netting, 1994).

Such ontological realism leads, almost inevitably, to the adoption of positivist and objectivist epistemological positions: observed systems are considered to be independent of those doing the observations while the knowledge that is gained through this positivist process is considered to be objective in the sense that there must be some 'permanent or ahistoric matrix or framework' to which appeal may be ultimately made 'in determining the nature of rationality, knowledge, truth, reality, goodness or rightness' (Bernstein, 1983). Moreover, because the hard systems approach was, by definition, held to be value-free, there was little that could sensibly be known or said about what ought to be done under circumstances where the indications were that something needed to be done (which, ironically enough, was itself was a normative judgement, of course). The issue of judgement became a key criterion of distinction for Vickers (1983) in his contention that human systems were so different that it was just not possible to study them using the logic and methods of the natural sciences, precisely because of the significance of judgement to human beings. His introduction of the notion of 'appreciative systems' – those sets of largely tacit standards of judgement by which we both order and value our experiences – as unique to 'human systems' dictated that they depended on shared understandings and shared cultural mores if they were to be effective and stable. A key feature of 'second wave' systemic thinking relates to the significance of human judgement to the placement, as it were, of systems boundaries (Midgley, 2000). This is in direct contrast to the 'boundaries as given' notion that prevailed within the 'hard school', and that persisted even when the concept was extended beyond the obvious – such as with the extension of the systems idea beyond obviously bounded individual cells and organs and organisms to include the much less evidently bounded 'ecosystems' in the form of the higher order 'biotic communities', as introduced by Tansley (1935).

These issues are far from trivial for they get to the very heart of the conundrum of why it is that the citizenry seems so reluctant to commit itself to learning its way out of the environmental mess that, paradoxically, many willingly acknowledge needs to happen. They also highlight some of the critical deficiencies of the environmental and ecological 'knowing systems' that are contributing to this paradox. Witness for instance, the long-standing ambivalence of ecologists with regard to the ontological status of human beings with respect to 'natural ecosystems', which does little to inspire the confidence of the citizenry. As Berkes (1999) has stated with such eloquence, within ecology, human beings are so frequently regarded either as somehow 'un-natural' components of 'natural eco-systems' or are placed into such mythological categories as the 'Ecologically Noble Savage', the 'Intruding Wastral', or the 'Fallen Angel'. To this, as has been already indicated, must be added the issue of the ontological status and organization of 'nature itself' and whether the notion of ecosystems as cybernetically regulated, stability-seeking entities that can evolve in all of their wholeness, can ever be empirically validated beyond mathematical representation. And what a sloppy concept 'nature' turns out to be under such circumstances, and 'society' too for that matter, and yet vocal is the claim that the new field of sustainability science for instance, 'seeks to understand the fundamental character of interactions between nature and society' (Kates et al, 2001).

The environmental sciences meanwhile have an even more difficult epistemic issue with which to contend, for in identifying the environment as their issue of concern, they are in fact nominating the 'other' as their 'it'. This creates a further source of epistemic confusion, for if the 'other' becomes the 'it' in any act of cognition, then the question arises of what now is the 'other' and what is the significance of the interrelationships between 'it' and whatever the 'other' is deemed to be? As well as being a matter of some epistemic significance to environmental scientists, this matter is also central to the contributions of environmental philosophers in their attempts to bring synthesis to what Belshaw (2001) has highlighted as 'reason, nature and human concern'. This focus well captures the claim that the quest for environmental sustainability must not only embrace what it is that could persist over time, but also, and essentially, what it is that should be allowed to persist (Thompson, 2004). It also illustrates a basic contention of Norton (2005) of what is needed if we are to intelligently discuss and learn about our environmental goals and how to achieve them: we will need a discourse which is rich enough to express and disagree about values – which perforce must include aesthetic notions of beauty as well as ethics – while also incorporating knowledge gained through scientific understanding. And all of this, as Norton particularly insists, demands communicative and cooperative behaviour of us within our communities in ways that allows clarification of epistemological and ethical assumptions as well as accommodating processes by which these can be safely challenged and, when appropriate, changed. As Grove-White (1996) has asserted, modern environmentalism has evolved 'not simply in response to damaging impacts of specific industrial and social practices, but also, more fundamentally as a social expression of cultural tensions surrounding the underlying ontologies and epistemologies which have led to such trajectories in modern societies'.

Such is the nature and focus of epistemic cognition; its importance returns our gaze to the concept of the 'knowing system' and a further application to it of the systemic principle of 'three dimensionality' with the suggestion that the *knowing system* be regarded as an integral subsystem of every system under consideration along with the environmental supra-system in which that, in turn, is embedded. This fresh 'three-dimensional' view is consistent with the emphasis in the hierarchy theory as being propounded by Ahl and Allen (1996) that the observers (knowers) need to be 'reunited' with the observed for it is they who are indeed responsible for recognizing boundaries around entities as well as proposing the criteria for making those distinctions. It is these 'knowers cum decision makers' who must make the judgements about who is to be included within the system of concern, what sort of knowledge will be needed and who can be relied upon to generate it, who it that should be the main beneficiaries of any indicated change, and who will speak for those unable to be present (Ulrich, 1983). In this view, systems are indeed in the eye of the beholder, as Checkland (1981) has asserted: they are abstract constructions of a concrete reality that cannot be directly accessed through the senses, or of a coherent set of processes for collective learning within a community of interest about what might be done to improve situations that they experience and appreciate as problematic to them in one form or another (and perhaps also to others). These perspectives, it is submitted here, are of profound significance to environmental concerns, and represent crucial ways by which these concerns can become known and can provide intelligible, trustworthy and collectively generated knowledge about both what *could* be done in the search for environmental sustainability and what *ought* to be done. In essence these demand different ways of knowing and reasoning and thus different rationalities, as Habermas (1984) has long insisted. Thus while his 'instrumental rationality' is entirely appropriate for exploring the 'external natural world', it needs to be replaced by 'communicative action' whenever and wherever the purpose is 'mutual understanding to realize common goals and values' (Yankelovich, 1991). These will demand access to epistemic cognition for their clarification.

With its own three-dimensional capacities for cognitive processing, the 'knowing system' as now envisaged, brings a learning and critically reflexive capacity as a subsystem to any system or systemically appreciated situation in which it embeds itself. As mentioned earlier, it draws on elements of all three waves of systems of thinking: it can consist of a tangible group of people (a 'hard' systems perspective) who commit themselves to behaving as if they were a coherent 'knowing system'. They will have a clear idea of the matters to hand that they are addressing, an unambiguous understanding of the systemic processes of knowing that they employ (a 'soft' systems perspective), and an inherent appreciation of the need to bring critical reflections (a 'critical' systems perspective) to all of these matters as well as to the epistemic aspects of all that, as a knowing system, it is trying to accomplish. Through their interconnectedness, each individual within the 'knowing (sub)system', will contribute to the collective process of knowing, to the knowledge that comes to be known, and to the democratic deliberations that are an essential property of that system. Each person learns with and through all of the others.

To behave effectively in this manner, knowing (sub)systems must have capabilities at all three levels of cognition, and must be prepared to allow for their own evolution as a knowing system as evidenced by collective intellectual and moral development. This last issue is of signal importance, for as Salner (1986) has emphasized, there is a strong correlation between the capability to think in any systemic way – and thus effectively use any systems methodology – and an advanced state of epistemic development. Drawing especially on the work of both Perry (1968) and Kitchener (1983), Salner argues that it is essentially not until one has learned the characteristics of an epistemological/ethical stance of what Perry referred to as 'contextual relativism' or 'contextualism' and has developed on from 'dualism', that one is able to develop effective systemic competencies. Addressing complex issues with any success, demands the development of complex meaning perspectives or worldviews (West, 2004), and that, in turn, demands critical attention. It is from a similar position that Bawden (2000, 2005) has made the claim that sustainable acts of development in the material and social worlds are functions of the intellectual and moral development of all of those who ought to be involved in those acts. This therefore brings a fresh, critical epistemic perspective to the calls for social learning as the foundations for the adaptive management of 'the environment', made by Keen et al (2005), and to support the quest for shared goals for sustainability and policies for greater environmental protection through public discourse which is 'holistic' in both its focus and its nature (Norton, 2005). As Norton readily concedes, the adoption of 'holistic adaptive management' as a social learning approach to environmental sustainability, presents a host of philosophical as well as practical challenges to all concerned, with the need for ethical, aesthetic, ontological and epistemological considerations to be taken seriously if we are ever to come to really know what to do better with respect to our relationships with the environment about us (Norton, 2003) – which represents 'the matter to hand', in the language of 'knowing systems'.

This perspective on social learning for adaptive management indicates the need for what is referred to as 'transformational learning' (Mezirow, 1991) that involves epistemological challenge and change, in contrast to 'informational learning' which is merely 'a change in behavioral repertoire or an increase in the quantity or fund of knowledge' (Kegan, 2000). A key distinction between the outcomes of these two forms of learning lies with their differential impact on the 'frames of reference or minds' that we use in structuring our knowing. Thus, as Kegan sees it, both kinds of learning are expansive and valuable, 'one within a preexisting frame of mind and the other reconstructing that very frame' or worldview: from the perspective of the three-dimensional knowing (sub)system being promoted here, this focus on 'changing frames' or – 'meaning perspectives' as Mezirow (1991) calls them – is directly analogous to the concept of 'epistemic development'.

It is perhaps most useful to conclude this piece with a brief reference to the meta-cognitive competencies – the learning how to learn and knowing how to know – that remain to be addressed here. In patent contrast to those who see learning as the acquisition of knowledge, Kolb (1984) presents it as 'the process by which knowledge is created through the *transformation* of experience'. From this experiential perspective, knowledge is continuously being created, recreated and 'used' by individuals as they seek to make conceptual sense of what they are sensing through their own experiences of the ever-changing 'concrete' world about them, as the essential prelude to taking sensible actions to adapt, or to adapt to, that perceived reality.

As Kolb sees it, it this adaptation that is the essential motivation for coming to know and learning: indeed, as he argues, 'learning is *the* major process of human adaptation' (Kolb, 1984, p32). Echoing one of the central themes of this chapter, Kolb insists that experiential learning is a 'holistic process' that involves constant transactions 'between the person and the environment' in a manner that engages 'the integrated function of the total organism – thinking, feeling, perceiving and behaving'.

But with that insistence, of course, Kolb reveals an epistemic position as well as a systemic orientation and logic, that is far removed from the dualism and reductionism that continues to prevail, ironically enough, within our formal institutions of learning and in our conventional knowing institutions which 'extract' the perceptual/sensual from the conceptual, and action from reflection, the subjective from the objective and so on. This Kolbian view of learning is as a quintessentially participative and transformative process in which the transformative power lies with both 'the whole' knowing system and 'its parts'.

Knowers develop a deep sense of the world that they are experiencing from the perspective of being 'embedded' within it and participating as part of it, even as they are trying to make sense out of it. Thus participation is an 'implicit aspect of wholeness', as Skowlimowski (1985) claims, which, in this learning/knowing sense includes, as Bohm (1987) emphasized, 'thoughts, "felts" and feelings' as well the 'state of the body'. Importantly, as Bohm also argued, it is a social process with 'thought passing back and forth between people in a process by which thought has evolved from ancient times'. This continuous 'unfolding' and 'enfolding' of meanings, thoughts, 'felts' and even intentions and 'urges to do things', cannot be anything other than a dynamic, systemic process of individuals and social groupings alike – and indeed of the mind itself. And all of this is very reminiscent of Goethe's participatory approach to a science through which he strove 'to enliven and deepen our understanding of nature' (Barnes, 2000). The Goethean scientist, claimed Bortoft (1996), 'does not lose himself or herself in nature, but finds nature within himself/herself in fully conscious experience'. Such conscious participation, is seen as a synergistic condition in which humanity and nature work together in such a way that 'each becomes more fully itself through the other'; a mutual enhancement.

A similar claim has been made for the synergy between the 'experiential knowing' processes of Kolb (as a subsystem) and what has been called 'inspirational knowing' by Bawden (1998); where the former refers to the transformation of experience into knowledge, inspirational knowing accesses 'innate insights' as its focus for transformation. It can be postulated that it is through inspirational knowing that we come to know our positions on 'rights' and 'virtues' and 'aesthetics' which are then synergistic with our experientially derived contexts and instrumental knowledge of the world, which we bring to bear in our communicative actions with others, to change our ways with it!

And all of this occurs within a learning (sub)system which has an internal ambience of emotions and dispositions that are embraced as essential to the transformative functions of that system.

Conclusion

As the above has indicated, a fourth, vital category can, and ought to be added to Berkes' (1999) typology: to the 'Ecologically Noble Savage', the 'Intruding Wastral' and the 'Fallen Angel' can/ought now be included the intrinsically three-dimensional 'Knowing Being'. Through their cognitive competencies, humans are capable of coming to know about matters to hand that concern them, coming to know how they come to know that, and coming to know the epistemic contexts in which these two 'lower order' processes operate (Kitchener, 1983). Such a knowing system can refer both to individuals and to social collectives of individuals. In functional terms, the 'triarchical' organization of this intrinsic human knowing system allows cognitive (level one) processing, meta-cognitive (level two) processing, and epistemic-cognitive (level three) processing to proceed in a synergistically interconnected manner. The epistemic dimension embraces all three of the essential 'elements' of human worldviews and paradigms – epistemology, ontology and axiology.

A key conceptual implication of the knowing system is the adaptation of the lower order systems to changes in the epistemic supra-system, which, it is suggested, tends to evolve (or be deliberately developed) from the relative simplicity of 'dualism' to the much more complex 'contextualism'. The paradox here, or at least the enigma, is that until and unless the knowing system evolves or is developed to this position, it cannot appreciate its own systemic nature (Salner, 1986).

The systems image can be further extended to present this intrinsically three-dimensional 'knowing system' as the key subsystem within an extrinsic, three-dimensional system-of-systems. A knowing (sub)system attempts to make sense out of what it senses in both 'the system' which it construes or 'brings forth' (Maturana and Varela, 1988) and of which it sees itself as an essential component part, and the environmental supra-system in which that system is construed to operate, and with which it is 'structurally coupled' (Maturana and Varela, 1988). In this manner it is possible to understand and present the 'environmental concern' as either a concern of the state of the immediate system, or of the environmental supra-system at large – but, and most significantly, only when that knowing (sub) system reaches an epistemic state that supports such a construction!

Therein lies the challenge of engagement with the quest for environmental sustainability and for the design of systems that are appropriately stable, resilient and influential to that end. Therein also lies the foundations for the provocative claim that all systemic acts of sustainable development in the material and social worlds are quintessentially functions of the epistemic development of those actors who need to critically engage with the issue. And the source of the provocative claim that all acts of development in the context of systemic sustainability will depend on the systemic appreciation (and thus epistemic development) of all of those who need to act in those circumstances.

Agricultural Sustainability: What It Is and What It Is Not

Paul B. Thompson

Philosophers spend a large part of their time scrutinizing words and concepts, attempting to get clear on what they mean, and on the implications of their meaning for human endeavours. Philosophical analysis of words and concepts yields a more explicit statement of assumptions that are generally taken for granted when people speak in a certain way. Analysis can reveal ambiguity that leads to confusion and miscommunication, and it can provide insight in how interpreting a concept in one way or another can lead to large and systematic differences in the way that two people using a single vocabulary approach a given topic. Programmes in sustainable agriculture apply human, biological and financial resources to the development of technology and social institutions. They generally draw upon agronomy and other agricultural sciences to research and disseminate tools and techniques that farmers can use, or they draw on the applied social sciences to support decision making and social organization to meet the local problems of rural communities. Philosophy is a very abstract activity, and sustainable agriculture a very concrete activity. What can they have to do with one another?

There are at least two points of contact. The presumptuous title of this paper is intended to convey the idea that philosophical debate over the meaning of sustainable agriculture will prove to be a useful and important exercise. Sustainable agriculture programmes are constantly subjected to criticism and debate about what, precisely, they should be doing. Some believe that resources should be allocated to agronomic techniques characterized by reduced chemical use or low inputs. Some believe that resources should be allocated to programmes that make farms of a certain scale or pattern of land use more profitable. Still others believe that conventional agriculture is just fine as it is, and that there is no need or basis for special programmes on 'sustainable' agriculture. Each of these viewpoints involves a different perspective on what it means for a farm, a production system or a more comprehensive food system to be sustainable. The variety of views on what it

Reprinted from Thompson P B. 2007. Agricultural sustainability: What it is and what it is not. *Int. J. Agric. Sust.* 5(1), Earthscan, London.

means to be sustainable has multiplied since the early 1980s, when critics of conventional agriculture began to claim that it was 'unsustainable'. The debate is no longer confined to agriculture. Others now want to talk about 'sustainable development', 'sustainable land use', and even 'sustainable architecture'. Yet few that participate in these debates have the time, inclination or skills to step back and analyse whether what separates them is a difference in values and perspectives, or a simple verbal dispute.

Philosophy can at least help clarify what is being disputed, even if it cannot resolve the dispute. It is possible that the philosopher's task will end when the terms of debate have been clarified. Yet I think that sustainability will turn out to be a contested concept of more enduring and fundamental interest. In some cases, our thinking and communication can be clarified simply by attending closely to a specific definition. Other times we find that a particular concept is so important to the way we understand ourselves and our world that we cannot gain mastery over it simply by specifying a definition for a given context. Concepts like 'truth', 'objectivity', 'causality', and 'justice' have been contested throughout human history. Such concepts have resisted our attempts to specify them in any final sense, yet it seems we must use these concepts to think at all. I believe that as we come to think more deeply and carefully about the impact of human activity on the broader environment and on the opportunities of future generations, we will find that our conceptions of sustainability have a tremendous impact on the way that we frame these problems. So philosophy encounters sustainable agriculture first by offering tools to better understand disputed visions of what sustainable agriculture might involve, and second because the debate over sustainable agriculture may well be the opening to an important new area for environmental ethics.

Encountering Sustainability

Philosophers generally began to take an interest in the concept of sustainability in the late 1980s, and I have been working on it myself for almost 20 years. My thinking on sustainability has two main phases. From about 1988 until about 1994, I was fairly sceptical and even cynical about the idea of sustainability. This is not to say that I was ever opposed to sustainable agriculture, for I was not. However, for about six years I believed that the debates over sustainable agriculture and sustainable development were driven by different conceptions of social justice, at best, and underlying economic interests at worst. Big fertilizer, seed and equipment firms thought that sustainability meant continued profitability for big fertilizer, seed and equipment firms, small farmers in Nebraska thought that sustainability means being able to continue farming at a small scale in Nebraska, advocates for Latin American peasants thought that sustainability meant social justice for Latin American peasants etc. My writing from this period argued there was little ethical significance to any claim putatively announcing that one type of agriculture was sustainable or that another was not. It was, I believed, much better to articulate the ethical claims that might be made on behalf of the environment, farmers, peasants or the capitalist system in more direct and conventional language. However, I did believe that there were important empirical questions to answer about whether a given practice or ensemble of technologies was or was not sustainable. By an 'empirical question' I meant that it is meaningful to question how long one would be able to continue doing what one was doing before scarcity of resources or some internal contradiction in one's practice would lead to its undoing.

There are three other dimensions to this early work that should be summarized. First, I believed then and still believe that it is impossible to answer the empirical question about sustainability without taking a systems view of agriculture, development or whatever practice is in question. By this I mean that no particular production technology, form of land tenure or other human practice is either sustainable or unsustainable in isolation. One examines a practice within a system context and then asks whether the total system is sustainable, presuming that what happens outside system borders remains stable. Taking a systems view, however, involves value judgements, and these value judgements open the door for philosophical inquiry and debate. It is, for example, possible to assess sustainability at the level of a farmer's field, and such an assessment might focus on nutrient exchange, the population of soil microorganisms or physical changes in the field due to erosion or soil compaction. Assessing sustainability in such terms presumes that the farmer is 'outside' the system. Not outside in the sense that the farmer's actions have no impact on the system. Rather, the farmer is beyond system borders in the sense that this way of understanding the sustainability of the field presumes that there will always be a farmer there to manage inputs. What if the continued presence of the farmer is itself in doubt? One can then reframe the question of sustainability by asking what system has to be in place to insure that a farmer (either a particular farmer, or any given farmer) will always be there to farm.

The broader point here is to illustrate how the definition of system borders involves a value judgement that frames the empirical assessment of sustainability. If one takes the farmer for granted, one gets one set of borders and a corresponding system that may consist largely of soil, water and microorganisms; if one asks how the farmer's continued involvement can be assured, one is dealing with a very different system, one that may involve banks, loans and government payments. Which of these perspectives, which way of defining system borders, is appropriate? My answer to this question is that it depends on what kind of practical problem one is trying to solve. Some people who write about sustainability seem to think that advanced systems modelling is a wholly value free process that will, through pure science, generate the information we need to save the planet. But my view is that the way that we conceptualize a system is deeply value laden, and reflects judgements about what is thought to be problematic, as well as likely guesses about where solutions might lie (Thompson, 1995). This point is also emphasized in Bryan Norton's recent work on sustainability (Norton, 2003, 2005).

Second, my discussion of sustainability and systems took issue with the viewpoint of Richard Bawden, from whom I have learned a great deal on sustainability on a particular question of ontology. Bawden was at the time arguing that systems are pure conceptual constructs, that there is nothing real about them. He had come to this view, I believe, out of frustration with systems theorists who had devoted what he took to be a pedantic concern with modelling physical aspects of systems and who had neglected elements of human praxis, not to mention the sense in which a system model is typically developed in response to a given felt need (Bawden, 1991; Bawden and Packham, 1993). In contrast, I argued that we would not be particularly distressed about instability or unsustainability of a system if we did not believe that the system was real (Thompson, 1995). The perishability of our conceptual constructs is not, in most instances, of great concern to us.

Pursuit of these ontological themes may prove to be an additional area where philosophers can be helpful in specifying an adequate concept of sustainability. The environmental philosopher Holmes Rolston III has argued against those who view wilderness as a 'social construction' in a similar vein (Rolston, 2001). However, a detailed pursuit of the ontological questions involved in systems science and in the definition of sustainability presupposes closure on a set of prior philosophical issues, namely those that describe the conceptual relationships between systems, system modelling and sustainability as such. It is these prior issues that are the primary focus of discussion below. A more complete discussion of ontological issues must be set aside for the time being.

Third, because of this systems approach, I have argued that it is possible for a person who is morally committed to sustainability to be overwhelmed by a more comprehensive and unsustainable system. By this I mean that someone who tries to farm or eat sustainably can be part of a society that is, in aggregate, doing itself in, and that there may be very little that any individual's commitment to sustainable farming can do about it. It is also possible for someone who neither thinks nor cares about sustainability to farm (or engage in other practices) that nevertheless contribute to the sustainability of the overall system. We can presume that many people in the past did so, for thinking and caring about sustainability is of comparatively recent origin. As such, it matters less that we promote sustainability as a personal ideal than that we pursue sustainability at a system level. This may mean that we are careful to maintain norms and beliefs that contribute to sustainability, even if they are not articulated as injunctions to pursue sustainability as such (Thompson, 1986, 1992). This aspect of my earlier views has drawn the most comment, as well as some caustic and critical responses, (see especially Campbell, 1998).

In 1994, several colleagues and I undertook a fairly extensive review of the way that people were defining and using the concept of sustainability in a variety of problem solving and policy contexts. Many of the authors we read were trying to find ways of answering the empirical questions that I had already identified as meaningful. This research did not lead me to recant my earlier views, but it did lead me to recast them. I recognized that attempts to answer the empirical questions would not be straightforward, and would involve a number of subtle value judgements. Furthermore, I came to the view that although there are dozens, perhaps hundreds, of distinct methodologies for measuring and pursuing sustainability through technical research, there are two broad paradigms for conceptualizing sustainability. These two paradigms did not contradict one another so much as they represented alternative approaches, each of which would tend to subsume the other. They differed in which questions they took to be most fundamental, and this difference had implications for how one would organize and conduct research on sustainability, how one would understand our ethical responsibility to make our practices more sustainable. The tension between these competing paradigms has also led me to think that there may be something of enduring philosophical interest here, after all. As a result, what I have been writing lately has a less cynical and more hopeful tone, and it takes sustainability more seriously.

Many of the technical approaches my colleagues and I reviewed conceptualize sustainability as a problem of *resource sufficiency.* People working within this paradigm arrive at working definitions of sustainability through the way that they approach two measurement problems. First, one must measure the rate at which a given production or consumption practice depletes or utilizes resources. Second, one must estimate the stock or store of resources available. The relative sustainability of a practice is then determined by predicting how long the practice may be continued, given the existing stock of resources. The other approach conceptualizes sustainability in terms of the *functional integrity* of a self-regenerating system. On this view, a practice that creates a threat to the system's capacity for reproducing itself over time is said to be unsustainable. This approach requires an account of the system in question that specifies its reproductive mechanisms, as well as an account of how specific practices, conceived as system activities, place those mechanisms at risk (Thompson, 1997, 1998a).

On reflection, however, I recognize that when I carve up the discourse on sustainability, I am actually left with three groups, rather than two. In addition to these two paradigms, I should add that there are still a number of people writing and talking about sustainability that seem to be making a *non-substantive* use of the word. There is a sense in which calling a practice or a pattern of conduct unsustainable is just a way of saying, 'You may get away with that this time, but eventually you'll be sorry!' This might point towards a deeper sense in which the practice or conduct will lead to its own undoing, but more frequently it is just a very general form of moral or prudential rebuke. In this sense, calling something 'unsustainable' is just a mild way of calling it bad. I was harshly critical of such talk in earlier publications, arguing that it just created confusion and muddled thinking. However, I must admit that mildness can be important, especially in the mid-west where the only thing worse than accusing someone of bad farming is to praise *yourself* as being a good farmer (or as knowing more about farming). In such contexts, the phrase 'sustainable agriculture' is just a polite way of saying 'good agriculture'.

One goal for this paper is to push my thinking on sustainability a little farther by exploring some of the implications of resource sufficiency and functional integrity within environmental ethics. Eventually, I will examine how these competing conceptions play out within the way that we understand our broad obligations to nature and to future generations, and this discussion should be relevant beyond agriculture. However, I would like to begin by returning briefly to some of the non-substantive uses of sustainability, and to consider how this way of talking about sustainability enables and promotes some very healthy activities within local *and* global debates. Here, sustainable agriculture is still my primary focus.

Non-substantive Sustainability

Dale Jamieson traces the concept of sustainable development from a 1980 report from the International Union for the Conservation of Nature and Natural Resources, through the 1987 Bruntland Commission report, to its current plethora of uses and applications. Jamieson concludes that the word is useful in structuring popular discussions and debate, but that it has little philosophical content or motivational power (Jamieson, 1998, p188). The philosophical indictment amounts to the claim that conceptualizing human activities in terms of sustainability does nothing to enhance our understanding of moral and prudential obligations associated with those activities. The second claim, that sustainability has no motivational power, amounts to the claim that characterizing one course of action as more sustainable than another will have little effect on human behaviour. I will consider these claims in turn.

First, Jamieson is right to point out that 'sustainability' is a good conversation starter, and a way to bring different interests to the table. What I have called *non-substantive* uses of the word 'sustainable' can be important in bringing people with different interests and values together. When this use generates definitions of sustainability, they tend to be highly general. Two economists offered this definition: 'We define sustainable agricultural development in this paper as an agricultural system which over the long run, enhances environmental quality and the resource base on which agriculture depends, provides for basic human food and fiber needs, is economically viable, and enhances the quality of life of farmers and society as a whole' (Davis and Langham, 1995, pp21–22). This definition acknowledges that agriculture feeds the human population, provides income for farmers and rural communities, and affects the environment, and in doing so it at least acknowledges multiple interests and multiple objectives. Yet has there ever been an agricultural technology or development project that was not intended to be sustainable, given this definition? Not every project succeeds in meeting these goals, but that just brings us back to equating 'sustainable' and 'good'.

Non-substantive uses of the term sustainable are often intended to link environmental impact with social justice. Gordon Douglass noted this in his 1984 essay on different approaches to sustainability. In most instances, authors simply assert that socially unjust practices are unsustainable (see George, 1992; Thrupp, 1993; Barkin 1998). Patricia Allen and Carolyn Sachs defend this use of the term 'sustainable', when they describe sustainable agriculture as a 'banner' under which a number of groups interested in environment and social justice have assembled (Allen and Sachs, 1992). Allen and Sachs argue that an adequate conception of sustainability must include the interests of labour, of the poor and of marginalized groups (Allen and Sachs, 1993), but this claim derives its warrant solely from the judgement that the interests of these politically weak groups should be adequately considered in any politically defensible discussion of agriculture. Allen and Sachs do not provide any argument for seeing why inclusion of these interests is related to sustainability as such.

This suggests that we can lump people who make non-substantive uses of sustainability into the 'mildness' camp and the 'banner' camp. Neither is particularly interested in what the word 'sustainability' might mean. The mild wish to use the term as a way of conveying approval and disapproval in an inoffensive manner. Banner waving organizers want to use sustainability to unify political and social causes. As Allen and Sachs (1993) are aware, one problem with the banner approach is that people with different conceptions of social justice are likely to propose different definitions of sustainability. Indeed, some authors writing on sustainable agriculture have equated sustainability with ordinary profitability, both for agricultural producers (Lynam and Herdt, 1989) and for agribusiness firms (Richgels et al, 1990).

Neither mildness nor banners get us very far in understanding what criteria should be brought forward in judging a practice to be sustainable, however. No one (well, hardly anyone) sets out to practice bad or unjust agriculture as his or her primary goal. Telling people that they should not be bad or unjust is virtually meaningless in the context of agriculture unless one also lays out some agriculture-specific criteria as to what bad or unjust means. The substantive debate concerns the standard according to which sustainability is to be judged, and this takes things beyond anything that mildness and banners can hope to accomplish. The debate over standards becomes acrimonious when either money or social approval is attached to sustainability. Everyone will want to make sure that sustainability is then measured in a manner that leaves them qualified for the rewards. People scramble to 'define' sustainability in ways that resemble the annual society page listing of who is 'in' and who is 'out', and what may have started out as politeness evolves into factional politics. Replaying the debate over social justice within a rhetoric of sustainability has not altered the familiar pattern of political alliances and ideological positions.

Non-substantive conceptions of sustainability are, thus, useful conversation starters, but the conversation does not go very far unless it eventually turns toward a serious attempt to understand what sustainability could mean in a substantive sense. The basic problem with non-substantive claims is that when we call something sustainable or unsustainable, we generally think that we are making a statement that could potentially be shown to be true or false. We thus need some conception of sustainability that does more than indicating mild approval or that reiterates the work being done by contested concepts such as social justice. One solution to this problem is to allow the values and interests of individuals working within a specific decision making context to determine the parameters of sustainability (see Walters et al, 1990). This has been the de facto approach of applied researchers for the last decade. The result is that the literature contains many technical definitions of sustainability that are inapplicable beyond the specific agronomic, economic or ecological problems for which they have been tailored. Can these problem specific approaches to sustainability be generalized?

Why Sustainability is Important

In the first phase of my work I approached the question of sustainability by asking whether it represented some sort of intrinsic good, or some comprehensive synthesis of goods. If this were the case, information about sustainability would be important because we would have an ethical obligation to pursue sustainability as such (see George, 1992). I concluded that this is not the best way to characterize the ethics of sustainability. The argument can be summarized by considering an extreme question. We can ask whether murder is sustainable in terms of resource sufficiency by measuring the rate at which murder consumes victims, and the number of victims available. We can ask whether murder is sustainable in terms of functional integrity by asking how murder threatens the human population's ability to reproduce itself. As an empirical matter, it seems likely that murder would turn out to be relatively sustainable, so long as more people are born than killed off. We are not inclined to view this fact about murder as anything in favour of the practice. We are not in the least inclined to say, 'Well, at least it's a *sustainable* practice.' From this kind of argument, I have concluded that we should view sustainability as an 'add-on' value, rather than an end in itself. Once we have deemed a practice worthwhile on other grounds, it becomes meaningful to ask whether it is sustainable, and to seek relatively more sustainable ways of securing the values or achieving the goals that make a practice worthwhile in the first place (Thompson, 1992, 1995).

Though sustainability is not intrinsically valuable, it may seem obvious that knowing which of several ways to further the sustainability of values is important for personal or social planning. Yet even this judgement needs to be unpacked. For example, consider a hypothetical problem for the resource sufficiency approach. Assume that we have determined that one food production strategy will produce a great deal of satisfaction for society at large over a few generations. Assume further that an alternative is more sustainable in that it will endure for a few more generations, but at such drastically reduced levels of satisfaction that there will be less total well-being produced even over the long run. It is not at all clear that we should choose sustainability in this case (Thompson et al, 1994). It seems we would choose the alternative that leads to more satisfaction overall.

This suggests that sustainability over time is just a dimension of the general utilitarian maxim proposed by Jeremy Bentham over 200 years ago. The maxim states that we should choose practices that maximize total well-being or utility, and Bentham describes several ways to measure utility. One of these is to increase the duration of pleasurable or satisfying experiences, but increase in duration can be swamped by increase in intensity or extent (i.e. in the number of parties experiencing satisfaction) (Bentham, 1789, p30). The underlying principle is optimization, not sustainability. Nevertheless, it must be admitted that even if sustainability simply points us towards the duration of well-being over time, it is worth including in a comparison of alternative social policies. Information about sustainability in the sense of resource sufficiency is important for planning, but not in a way that adds anything to the traditional statement of utilitarian philosophy.

So far, the argument does not provide any basis to contradict Jamieson's judgement that there is nothing novel or philosophically interesting about sustainability, but perhaps this is simply a result of the resource sufficiency approach. To examine this possibility, consider again the practice of murder. Taking first the sustainability-as-duration idea suggested by the resource sufficiency approach, we could argue that society's capacity to sustain a murder rate over time is of little value because the costs or harms associated with almost any given murder outweigh any benefits. Lengthening the duration of a murder rate for society might be a good thing in comparison to an alternative where the murder rate increases, but not because of sustainability. The moral judgement is simply a matter of the total welfare produced by each alternative. Duration, again, is only a dimension of the increase or decrease in total utility, total benefit and harm.

Switching to a functional integrity approach, we ask how murder threatens a society's ability to reproduce itself. We might first assess the question in terms of biological births and deaths, but the sustainability of murder is, on the face of it, a much more complicated question than whether there are enough victims to keep up the killing. We are led immediately to consider whether a given murder rate, or perhaps murders of a particular kind or within a particular sector of society might threaten democratic or family institutions. Answering these questions might, in turn, lead us conclude that even if the birth rate is adequate to supply a continuous stream of victims, murder *does* threaten a society's ability to regenerate its fundamental institutions. *This* conclusion adds something to the urgency with which murder is understood as a social problem. The harm done by murder is itself sufficient reason to expend resources on police and courts, but the stakes are even higher when we become convinced that it threatens fundamental institutions.

I believe that a similar comparison can be made for ecological, environmental and agricultural applications of these two approaches, though the issues are more complex. If we take a resource sufficiency approach to food production, the problem is still one of balancing costs and benefits. The accounting becomes very complicated and contentious, in part because there is little consensus about the environmental costs of food production. There is far less agreement than with respect to the costs and benefits of murder. Yet if we did reach consensus on the costs and benefits of food production, the value of sustainability would be entirely subsumed in this larger optimization problem. We would compare the relative costs and benefits of different ways for producing food. The comparison would be made difficult by the disparity between different kinds of cost or benefit (e.g. gustatory *vs* nutritional value; producer *vs* consumer benefit; human *vs* ecosystem health), but sustainability-as-duration would certainly be one of least difficult aspects of the comparison to accomplish.

Consider then how food production affects our society's ability to reproduce itself. This, too, is a problem of almost overwhelming complexity, for society must be understood as a system comprising many subsystems that are threatened in different ways by different approaches to producing food. One aspect of social reproduction is the regeneration of our bodies, a reproductive process that requires food consumption. The human population's need for food sets one system parameter, but in meeting this parameter it is possible to deplete soil, water and genetic resources used in food production. Since each of these is a regenerative subsystem, threats to these subsystems represent threats to total system sustainability. Similarly, farms and rural communities represent subsystems. If farming is unprofitable, or if the local institutions that support farming are not regenerated, the sustainability of the larger system is threatened. Our desire to maintain the functional integrity of all these subsystems might make us conservative in the sense advocated by Edmund Burke. That is, we might be very cautious about 'improving' a subsystem that seemed to be functioning well enough for fear that what we would do might upset the complex interconnection of the whole.

Far from understanding sustainability as one dimension of optimization, we would understand it as a relative equilibrium among social and natural subsystems, an equilibrium that we challenge at our peril. We might say that we value these natural and social subsystems because they provide the context or the constitutional basis for personal and group identity, and for the formation of preferences that would give rise to a given conception of well being. Nevertheless, I believe this stops short of making sustainability into an intrinsic value, for we would feel considerably less compunction about interfering in a system that did not seem to be functioning well. It might be worth some risk, in other words, to change a social system that produces wretchedness and social injustice in large measure. I also hasten to add that this conception of sustainability would not entail conservatism in every case. If our knowledge about threats to system integrity indicated that our food production system was headed for collapse, sustainability-as-functional integrity would provide a basis for even extreme restorative measures.

We may summarize and tie this discussion to a broader literature in ethics and political philosophy. Resource sufficiency points towards an interpretation of sustainability as a measure of the duration associated with practices that produce (or detract from) well-being. It leaves questions about whose well-being and the relative measure of different forms of satisfaction open. It is consistent with the general form of the utilitarian maxim, and indeed seems to specify nothing more than the temporal dimension of it. It is therefore an important component of the information we need to carry out moral and political duties conceptualized in utilitarian terms, but it is not particularly interesting from a philosophical perspective.

Functional integrity, however, describes the mechanisms that allow whole systems, (such as human societies or human dominated ecosystems) to regenerate themselves over time. System-level stability manifests itself in social institutions, renewal of soil, water and genetic resources (including wildlife), and cultural identity. The basis of our obligation to maintain this stability is sometimes obscure but can be expressed as prudential advice to be cautious about very uncertain risks. It may also be expressed in more communitarian terms as a duty to maintain the integrity of institutions and natural processes that are the basis for our collective sense of identity and purpose.

Resource Sufficiency *vs* Functional Integrity

The concepts that have been sketched out above are problematic in more ways than can be discussed in a single essay. The problematic character of these general approaches to sustainability is what accounts for their philosophical significance. If sustainability were just the temporal dimension of a maximization rule, it would not merit much philosophical analysis. But sustainability is a contested concept, with functional integrity advocates claiming that it describes part/whole relationships in a way that is central to socio-natural organization of human activity. It is therefore worth taking some pains to clarify and understand what is being contested, and how functional integrity is different from resource sufficiency. The present format avails scope for discussing only one dimension of this comparison and contrast, so the goal here is not to exhaust the philosophical analysis of sustainability but merely to tease readers into a continuing philosophical discussion. What is more, resource sufficiency and functional integrity are not so easily distinguished once empirical analysis begins. There is less difference in the way that these two approaches portray the facts than might appear. However, the empirical interconnections only serve to underscore the way that advocates of each approach are interpreting facts normatively different ways.

Any attempt to carry out the empirical measurement and system modelling implied by resource sufficiency and functional integrity will tend to bring these two approaches to sustainability together. Consider what an analyst attempting to evaluate the sustainability of a given strategy for food production would do. Measuring the resources needed to produce food would lead one immediately to renewable soil, water and genetic resources. Accounting for the availability of these resources over time requires knowledge of the rates at which they are replenished. The resource sufficiency analyst is thus led to many of the same questions as the functional integrity analyst. Production strategies that maintain the functional integrity of regenerative subsystems for renewable resources are likely to come out as 'more sustainable', on either the resource availability or the functional integrity approach.

Given this similarity, why is there a debate at all? Jamieson reviews the debate between advocates of *strong sustainability*, who insist that natural capital must not decline over time, and those who advocate *weak sustainability*, that is, that human well-being does not decline over time. Both groups operationalize their respective conceptions of sustainability with accounting arguments of a resource sufficiency kind. The primary difference is that weak sustainability presumes that one means for maintaining human well-being is as good as any other. Crucially, they believe that it will be possible to maintain well-being by substituting human for natural capital (see Pearce, 1993). Advocates of strong sustainability believe that future generations have a right to the same amount of natural capital as present generations, and that protecting this right places a prior constraint on preference maximization by present generations (Howarth, 1995; Bromley, 1998). Norton also stresses the difference between strong and weak sustainability as approaches in ecosystem management (2003, 2005). Here again, I will emphasize agriculture.

Strong and weak sustainability represent significantly different perspectives for evaluating agriculture. Specifically, advocates of weak sustainability may see agricultural science as a way to compensate for declining soil fertility, water quality or genetic variability. To say that human capital is substituted for natural capital is economists' talk for saying that science will continue to increase yields, even as the renewable resource base declines. Norton and other advocates of strong sustainability reject this strategy, claiming that it violates the rights of future generations. This approach is consistent with resource sufficiency approaches to the measurement of sustainability. It is consistent with the welfarism of utilitarianism (i.e. the view that it is the well-being of individuals that is ethically important) and differs from classical utilitarianism primarily in 'taking rights seriously', in this case, the rights of unborn future generations. Thus the basic philosophical machinery in this approach to strong sustainability is consistent with recent work in ethics and political theory that is largely unconcerned with and uninformed by ecology or principles of functional integrity. Key work in reconciling rights with the consequentialism (i.e. understanding ethics as being intrinsically engaged in the comparing the expected consequences of alternative courses of action) was accomplished by Ronald Dworkin (1977) and Amartya Sen (1987). This approach does not demand a systems analysis or orientation, and presupposes only that one has some reasonably reliable means for predicting the consequences of one's action, generally as a sequence of causal relationships.

Yet one wonders whether there is not a functional integrity argument lurking in the background of strong sustainability. One way that systems can creep in to the strong sustainability view is when predicting the consequences of human action is done using models that are, effectively, systems-based. However, this makes it seem as if the predicting is purely a scientific activity. One of Norton's key points (2003, 2005) is that it is important to avoid a 'value-free' notion of science precisely because doing so conceals key value judgements that may have been made in conceptualizing system borders. The chance of such concealment is significant when the systems orientation is buried in the model being used to predict outcomes. Thus one philosophical advantage of functional integrity is that the language in which sustainability is articulated invests the system of interest with significance in an obvious way. Clearly, the only way that natural capital can be preserved consistent with rights of present generations (let alone future ones) is to utilize renewable natural resources within their capacity for regeneration and renewal. In *saying* that sustainability is about the integrity of the renewable resource subsystem, as opposed to welfare or rights, one surfaces the values implicit in viewing natural resources as a system capable of regeneration.

Another argument for resisting the dependence on science that is implicit in a resource sufficiency approach also points us toward functional integrity in stressing that key vulnerabilities reside in social (rather than soil and water) subsystems. First, if science is generating the technology crucial to meeting food needs, we must be sure that the subsystem that supports agricultural science is itself secure, and that there are good reasons to think that continuous increases in yield are in store. Yet funding for agricultural science has declined steadily over the last decade, and as the number of farmers who lobby for research declines, it is not at all clear that social apparatus needed to support the research system is stable (Buttel, 1993). Second, increases in yield have been accompanied by patterns of industrialization in agriculture that deplete rural populations, and that shift farmers' economic livelihood away from dependence on soil, water and genetic resources, and toward dependence on finance. This shift strikes to the heart of the sustainable agriculture movement, for people fear that the social and biological systems that support agriculture have been weakened, and that farming has shifted toward greater dependence on an inherently risky system for regenerating financial capital. Each of these subsystems is seen as becoming more brittle as we drift towards industrial agriculture.

I am not asserting that risks to the science subsystem or the rural community subsystem have been proven. My point is simply to sketch the implicit links between strong sustainability and a functional integrity point of view. However, this sketch does suggest that a more explicit statement of the functional basis for imputing rights to future generations would result in a more plausible and more potent philosophical statement of the case for strong sustainability. Although advocates of strong sustainability use the accounting language of resource sufficiency, it seems likely that their conservatism derives from a deeper consideration of the way that food production depends on the continued performance of many interlinked subsystems. They believe that unbridled industrial agriculture poses significant risks to the stability of social, scientific, financial and renewable resource subsystem. They therefore challenge the weak sustainability estimate of resource availability. Ultimately a defense of this viewpoint depends more heavily on a plausible account of risks to system integrity than on the imputation of rights to future generations.

Conclusion

Jamieson's negative assessment of the philosophical richness in various conceptions of sustainability is unwarranted. Even if one is inclined to favour a simple norm of optimization, one must admit that resource sufficiency and functional integrity present philosophically complex alternatives for conceptualizing the nature of human responsibility to act sustainably. However, I am only slightly less pessimistic than Jamieson about the motivational effectiveness of sustainability. On the one hand, I hope that I have shown why sustainability is important, and why getting a clearer understanding of sustainability is crucial to policy planning and project management. On the other hand, the sheer complexity of sustainability (the fact of which is part of my argument for treating it as a philosophical problem) weighs against its use as an idea that can mobilize mass political movements. It is questionable whether it can be useful in motivating individual behaviour.

This leaves us with the paradox of sustainability. On the one hand, the human polity ought to act sustainably. On the other hand, the human polity cannot mobilize around the goal of sustainability. Looked at in one way, there is no contradiction here. It is just a way of saying that it is better to be lucky than smart. If we have simple norms that provide little insight into the regenerative systems of ecology and society, but that guide our behaviour in ways that allow those systems to function, we should retain those simple norms. We ought *not* replace them with complicated conceptual or mathematical models that are 'smart' in providing predictive knowledge of system failure, but that are too complex for people to follow on a day-to-day basis (Thompson, 1995; Grant and Thompson, 1997).

While not strictly paradoxical, the upshot is at least ironic. Though we ought to improve our understanding of sustainability in a deep sense, and despite the fact that non-substantive discussions of sustainability make this more difficult, non-substantive talk about sustainability may be more sustainable (in the sense of promoting a genuinely sustainable society) than reforming the public discourse with an ecologically and philosophically richer idea. Mora Campbell has taken me to task for advocating this position. She claims that since my conceptualization of sustainability establishes a system perspective that is unavailable to people making decisions on a day-to-day basis, I have established a normative framework that is inherently elitist and exclusionary. According to Campbell, a conceptual apparatus that demands an ideal observer's perspective for establishing its normative claims is normatively unacceptable because any acceptable normative perspective must, in principle, be accessible to all (Campbell, 1998).

Campbell does *not* mean that every person must be able to 'occupy' or have deep affective sympathy with a perspective for it to have moral validity. That would be contrary to the general principles of the feminist critique her paper undertakes. Feminist thought in environmental ethics has promoted an interpretation of rightness (or the normatively correct) that is capable of accommodating deep incompatibilities in perspective (Warren, 2000; Plumwood, 2002) This is not the place to launch into a detailed discussion of feminist thought, but Campbell's critique shows, contra Jamieson, that even if my approach to sustainability is motivationally weak, it is weak in a philosophically interesting way.

In reply I offer two concluding disclaimers and qualifications that hopefully deflate the elitist and exclusionary pretensions Campbell associates with my position. First, although I have argued that the systems-modelling approach to sustainability yields a conceptualization more adequate to the task of reforming conduct and policy, I have *not* argued that adopting this approach is either a necessary or sufficient condition for adequate moral decision making. Normative inquiry is complex and I agree with the main thrust of the feminist critique: it is important to both figuratively imagine and to actually conduct inquiries into the norms and goals that guide our lives in an open and welcoming manner. We should not dismiss different views as 'irrational' nor should we try to police our normative discourse in light of philosophical conceits. We should instead try to hear and accommodate each other's voices (Thompson, 1998b).

Second, I have *not* argued that we should allow the numbers that hard systems models generate to override other considerations when reviewing how to adjust our conduct or policy. Indeed, I do not think that specific predictions and measurements of either resource sufficiency or functional integrity should be given much weight at all. In fact I think that it is very likely that current models omit crucial factors and that to rely on them too heavily in policy making would be to fall victim to the fallacy of 'state simplifications' (Scott, 1998). The argument that I *have* made is that the systems-modelling approach yields an informative and normatively more adequate *conceptualization* of sustainability, one that gives us a better sense of what we are shooting for, one that helps us better understand what our adjustments, approximations and ameliorative strategies should be striving toward. Models can also reveal patterns of association and interaction that tend to be maintained among various system elements, including human activity. Such revelations are normatively useful, even when the predictions are imprecise.

In my view, sustainability is neither equivalent to norms that we have long associated with democracy and social justice, nor should it be presumed that achieving these norms will necessarily result in a sustainable society. Yet people seeking to make their societies more sustainable at the same time that they seek to make them more democratic or more just would be well advised to develop an understanding of sustainability that has been informed by the lessons of ecology and systems modelling. They should also regard the definition and conceptualization of sustainability as a philosophically open ended and always evolving task. We will never have a complete understanding of sustainability; we must always be willing and eager to think it through again.

Learning and Mislearning

Robert Chambers

How we learn and mislearn about canal irrigation systems has not itself, to my knowledge, been a subject of research. Yet how our beliefs are formed and sustained deserves a hard look. This chapter examines examples of research and innovation. Two sets of accessible data are considered. The first is three studies made of the left bank of the Mahi-Kadana Project in Gujarat. The second is action research undertaken on the Mahanadi River Project and Hasdeo Bango Project in Madhya Pradesh. In analysing these, and in subsequent discussion of pilot projects and 'islands of salvation', my approach is critical. But it is easier to criticize than to do. It is not hard to find holes in any pioneering research or action, especially when the arena is as complex and varying as canal irrigation. The courage of those who run the risks of research and action is to be applauded. The spirit of this chapter is positive, to learn lessons and to contribute to the collective struggle, to get closer to the truth.

Mahi-Kadana: Seeing Parts and Missing Links

Unusually, the Mahi-Kadana Project in Gujarat has been the subject of three separate and substantial multidisciplinary studies, each with a different purpose, orientation and disciplinary composition. Each study reveals different aspects of the project, and leads towards different practical conclusions.

The Mahi-Kadana Project itself developed in two stages. The first was the construction of a weir across the river Mahi at Wanakbori in 1958. This diverted run-of-the-river flows primarily for the kharif (monsoon) season, to supplement rainfall. The second stage was the construction of the Kadana reservoir upstream, in 1978. Storing and releasing water from this reservoir was designed to enable rabi (winter) and summer crops to be grown. The three studies were concerned with the larger Mahi Right Bank (MRB) and not the smaller Mahi Left Bank, and all discussion and figures which follow refer only to the MRB. In 1980–1981, the Cultivable Command Area of the MRB was reported to be 213,000ha, with an

Reprinted from Chambers R. Learning and mislearning. In *Managing Canal Irrigation.* Cambridge University Press, Cambridge 1988

irrigation intensity of 55 per cent as against 131 per cent proposed by the Government of Gujarat (WTC, 1983, p356). A Command Area Development Authority (CADA) programme was launched in 1974, and was concerned with on-farm development (OFD) and later with farmers' organization for the distribution of water, all of this below the outlet. The main crops were paddy in kharif and wheat in rabi, with also a large area under eight-month tobacco. The period during which the three studies were conducted was also that of the first five years of flows from the Kadana reservoir, when rapid changes were taking place in the MRB as the extra water was available, including extensive OFD work under the CADA programme.

The three studies had different purposes and were conducted by researchers from different disciplines, as shown in Table 5.1.

The first and earliest study, *Command Area Development in Mahi-Kadana* (Asopa and Tripathi, 1978) was carried out by two staff members of the Indian Institute of Management, Ahmedabad – an agricultural economist with a background in

Table 5.1 *Three studies of Mahi-Kadana Right Bank command area*

Institution	*Stated purpose*	*Title of publication*	*Disciplines involved in study*
Indian Institute of Management, Ahmedabad	An in-depth understanding of the integrated area development approach in the command area	*Command Area Development in Mahi-Kadana* (Asopa and Tripathi, 1978)	Agricultural economics Agriculture Sociology
Water Technology Centre, Delhi	Broad objectives included 'the resource analysis of the project area and development of guidelines for efficient land use and water management in the MRBC command area'	*Resource Analysis and Plan for Efficient Water Management: A Case Study of Mahi Right Bank Canal Command Area, Gujarat*, (WTC, 1983)	Agricultural engineering Hydrology Agronomy Biometrics Statistics Soil physics Water conservation engineering Soil science Climatology Agricultural economics
Water Management Synthesis Project, Colorado State University	Training, and also 'to describe the actual operation on an irrigation system in relation to design specifications, and to identify the positive and negative aspects of the system through an interdisciplinary analysis'	*Diagnostic Analysis of Farm Irrigation Systems in the Mahi-Kadana Irrigation Project, Gujarat, India* (WMSP, 1983)	Agronomy Economics Irrigation engineering Agricultural engineering Extension/sociology

agriculture, and a sociologist. They noted that the World Bank-assisted programme in the command of Mahi-Kadana was one of the first few attempts to implement the command area development approach.

Their study was an attempt at gaining an in-depth understanding of the integrated area development approach in the area. The specific objectives were to study the planning of the integrated area development programme, to understand the implementation processes, and to assess the farmer's perception of the programme, his needs and receptivity (Asopa and Tripathi, 1978, p12).[1] There was no requirement to produce a plan. The method included study of documents, interviews with knowledgeable people and a survey of 50 farmers to know their reactions to the philosophy of the programme, its implementation and its usefulness in increasing agricultural production.

Asopa and Tripathi wrote a 112-page report which was ahead of its time in the stress it laid on farmers' participation in decision making for water scheduling, rotation periods and other aspects of water management They argued that 'the major lacuna continues to be either limited or erratic availability of water'. As long as that continued, 'no amount of administrative innovativeness, support or vigilance would promote irrigated agriculture'. They proposed water cooperatives which would distribute water and ultimately become bulk purchasers of water (Asopa and Tripathi, 1978, pp103–109). This was, then, a study which set out to examine Command Area Development and farmers' views, and found its attention directed by the farmers towards the main system and water scheduling and delivery.

The second study, *Resource Analysis and Plan for Efficient Water Management: A Case Study on Mahi Right Bank Canal Command Area, Gujarat* (WTC, 1983) was carried out by some 16 scientists of the Water Technology Centre (WTC), Delhi, including the disciplines of agricultural engineering, hydrology, agronomy, biometrics, statistics, soil physics, water conservation engineering, soil science, climatology and agricultural economics. The report (WTC, 1978, p7) states that:

> The broad objectives of this programme include the resource analysis of the project area and development of guidelines for efficient land use and water management in the MRBC command area. The studies included the collection, compilation, analysis and interpretation of all available data and information on the irrigation project.

Secondary data were collected from official sources, and primary data were collected on soils.

The 360-page report reflects the disciplines of those who took part. The main chapters, after an introduction, are:

- Climate.
- Soils.
- Irrigation.
- Drainage.

- Groundwater Development and Management.
- Impact on Environment.
- Canal Scheduling and Water Course Alignment.
- On-farm Development.
- Ancillary Resources and Infrastructure.
- Irrigation Cooperatives.
- Crop Planning and Irrigation Management.
- Water Resources Utilization and Management.

Disciplinary specialization, quantitative methods and the presentation of statistics are marked in most chapters. The focus on water is strong, with descriptions of the physical irrigation system, the official norms for system management and operation, annual water balance calculations and analysis of groundwater conditions. Groundwater was found to be rising at about a metre a year during 1976–1980, threatening waterlogging and salinity. A final chapter by P. B. S. Sarma, N. H. Rao and A. M. Michael on 'Water Resources Utilisation and Management' examines the water resources assessed as available, and the original plans for the system, which did not include extensive use of groundwater. Sarma and his colleagues propose conjunctive use of groundwater. With conjunctive use, they calculate that the intensity of irrigation, based on a Culturable Command Area of 213,000ha, could be raised from the 55 per cent reported achieved in 1980–1981, and beyond the 131 per cent proposed by the Government of Gujarat, to 180 per cent (WTC, 1978, p356). This would simultaneously help to arrest the rise in the groundwater table and increase the intensity of irrigation.

The third study, *Diagnostic Analysis of Farm Irrigation Systems in the Mahi-Kadana Irrigation Project, Gujarat, India* (WMSP, 1983), was an outcome or by-product of a five-week professional development diagnostic analysis workshop held in early 1981 as part of the United States Agency for International Development (USAID) supported Water Management Synthesis Project (WMSP), the main objective of which was training. Studies were carried out by trainers and participants in the disciplines of agronomy, economics, irrigation engineering, agricultural engineering, and extension and sociology. The objectives of the workshop were:

1. to provide the participants with the skills required to monitor and evaluate irrigation projects, thus enhancing the capacity and the capability of the government to improve irrigation facilities and management throughout Gujarat;
2. to describe the actual operation of an irrigation system in relation to its design specifications, and to identify the positive and negative aspects of the system through an interdisciplinary analysis. (WSMP, 1983, p3)

The authors of the report note that the training objective deliberately restricted the amount of data collected, so that the report simply indicated areas of constraints in the system.

The method included interviews with staff and farmers and detailed interdisciplinary field investigations at the on-farm level including measurements of water flows. The main system was included but the principal focus was below the outlet. The report is unusual for the attention given to the problems and views of both officials at different levels, and farmers. This emphasis is reflected in the sequence of sections in the report, starting with extension, and then with economics, engineering and agronomy in that order.

Three findings deserve remark. First, most farmers were found willing to pay seven to nine times more for private tubewell water than for public canal water. This was because tubewell water was predictable and controllable (WSMP, 1983, p52). Second, flows through outlets, far from being constant, were highly variable during both day and night as they were also in the canals (WSMP, 1983, pp87, 89, 99, 102, 136). And third, conveyance losses below the outlet were estimated to be 50 per cent (WSMP, 1983, p110).

Analysing and comparing these three studies, three points stand out.

Partial views and complementarities: Each study reflects the interests and methods of the investigators, covers a different range of topics, and leaves much out. If the proper names were excluded, one might not know that the three texts referred to the same system. However, when taken together, the three studies are complementary, and qualify and correct each other. For example, the WTC study includes a water balance analysis which is not based on empirical measurements of transmission losses, and assumes losses of 30 per cent below the outlets. The WMSP study found empirically that losses averaged about 50 per cent below three outlets. If 50 per cent is representative, then the WTC estimates of water availability and potential intensities for the whole system should be much lower.

Mutual ignorance: Asopa and Tripathy reported in 1978, yet I have been unable to find any reference to their work in the WMSP and WTC reports published in 1983. T. K. Jayaraman (1982) wrote prolificly on Mahi-Kadana (on cropping patterns, farmers' organization, on-farm development, rotational water supplies, the attitudes of the irrigation bureaucracy etc.), but the only mention of his work I can find in the WTC report is a paper on malaria (Jayaraman, 1982). Most striking of all, the WMSP and WTC teams appear to have worked in ignorance of one another. The complementarities which might have been exploited to mutual benefit were not realized.

Missing links: The three studies sometimes touch upon, but do not investigate in detail, key linkages and gaps in knowledge. In a common sense view of Mahi-Kadana as a system, missing links likely to be significant might include:

- Labour shortages at peak periods.
- Actual flows and regulation of the main system.
- Irrigation flows at night.
- Farmers' activities above the outlet.
- Farmers' costs (in payments, hassle, time, uncertainty) in obtaining a water indent.

- Farmers' knowledge of main system management and water supplies, and manager–farmer communications.
- Incentives and disincentives for irrigation staff.
- The operation of the groundwater market.

None of these are examined in any depth in any of the three studies. Without more insight into most or all of these, prescription for improving performance might easily be wide of the mark.

MRP and HBP: Failure through Success

In kharif 1979 the consultants Water and Power Consultancy Services (WAPCOS) conducted ambitious and inherently difficult research on two major canal irrigation projects – the Mahanadi River Project (MRP) (CCA about 180,000ha) and the Hasdeo Bango Project (HBP) (CCA about 41,000ha), both of which grew paddy in kharif with protective irrigation. The objective of the research was to ascertain the advantages, if any, of reducing chak size. Normal chak sizes ranged from 8ha to over 200ha. The experimental treatment reported was to subdivide trial chaks by constructing subminors down to 8ha subchaks, and then rotate the water supply between the subchaks. Of 14 outlets selected, 3 became trials and 11 were controls. Measurements reported included water supplied, rainfall, farmyard manure and chemical fertilizers used, percentages of chaks and subchaks planted to high-yielding varieties (HYVs) and transplanted, and yields at different locations in chaks and subchaks, using crop-cutting. It was reported for WAPCOS (Chadha, 1980, p388) that these field studies:

> demonstrated dramatically the effect of delivering water through Government constructed channels up to smaller chaks (of 8ha in this case)... Our recommendations, supported by field studies carried out as part of consultancy services are for 8ha subchaks which means that the size of subchak was limited to 4 or 5 farmers, and length of water course serving it is limited to 300m or so, which are much more manageable. It is a matter of happiness that Govt. of India also accepted these findings and have issued new guidelines on the subject.

The adoption of these recommendations as government policy is confirmed by the record of a conference held in April 1980 which reported the then Secretary of Irrigation as saying:

> The Government of India and the Planning Commission have requested the State Governments to extend field channels to 5–8 hectare blocks, on the canal system. (Patel, 1981, p9)

Let us examine the methods and evidence of the research on which, it would seem, this policy decision was based. In doing this, the most favourable assumptions will be made. The measurement of water flows, of input supplies and applications, of areas under HYVs and transplanted, and of crop yields through crop-cutting are all subject to methodological problems, and often wide margins of error. Although there is no reason to suppose this research was exempt from these difficulties, and although the WAPCOS report makes no mention of them, the critique which follows assumes complete accuracy of measurement and reporting. Full acknowledgement must also be given to the difficulties recognized by the researchers. The 1979 monsoon was poor and less water than normal was available, especially on the HBP. Low rainfall affected crop yield directly through water scarcity, and indirectly through increased pests and diseases. Cultivators were free to use whatever inputs they wished, weakening some aspects of the comparison of trial chaks with control chaks. The Government of Madhya Pradesh could only construct channels down to subchaks for three outlets – two on MRP and one on HBP. Finally, of these three, the one on HBP received very little water, and one of the two on MRP had a severe attack of gall midge.

In its conclusion, the WAPCOS (1980) report stated that it had briefly reviewed 'Exhaustive, most valuable and reliable data as collected', and then summarized its findings. Some findings were also presented in a subsequent paper (Chadha, 1980). Those especially relevant to the policy decision for smaller subchaks were:

1. *acceptance*: subdividing of a large outlet chak into smaller subchaks as irrigation units found general acceptance from the cultivators (WAPCOS, 1980, p30);
2. *time taken to irrigate*: 'the time taken for irrigating the entire command of an outlet was 5 to 14 days as against 20 to 45 days for normal outlets without subchaks' (Chadha, 1980, p388. Chadha, 1981, p70 specifies this as the time for providing first irrigation);
3. *uniformity of yield*: the variation in yield within an outlet command was less when it was divided into smaller units (WAPCOS, 1980, p30);
4. *yield*: with smaller subchaks yields were 70 to 137 per cent higher compared to the normal outlets (Chadha, 1980, p388).

The syntax used in both sources implied that the benefits were the result of the experimental treatment of subdivision and rotation.

The procedures and analysis throw doubt on the validity of these conclusions. To understand why, we must look at the detail of the procedures and analysis employed. Three methodological defects can be noted.

First, two of the three trials were eliminated from most of the comparisons because they performed badly, but none of the 11 controls was eliminated. In mitigation, none of the controls was reported to have suffered as severely as these two trials from their respective problems – a gall-midge attack, and receipt of very little water respectively. All the same, no analysis was made of the reasons for the gall-midge attack or the little water received or whether these were related to the trial treatment. Nor was the failure to eliminate any of the controls discussed or justified. Most of the conclusions were based on the one remaining trial chak with subchaks, the Koliary outlet, comparing its performance with that of the 11 controls.

Second, the Koliary outlet had a privileged location compared with the controls as a whole. It was accessible to administrative headquarters at Raipur. It was on the MRP which had more water than the HRP. It was selected because it would be possible to assure a water supply. And it was well placed on the canal system, being at the head of a distributary at the head of the canal. The relative positions are shown in Table 5.2.

Third, the Koliary chak received special treatment. Before the kharif season, the farmers on the Koliary outlet were asked if they would be prepared to plant

Table 5.2 *Details of trial and control chaks, MRP and HBP*

HYVs, use fertilizer and transplant. They said they would do so only if their water supply and other inputs were assured. This was agreed. Special efforts were made with the bank, and with seed and fertilizer supply, to ensure that farmers could obtain the necessary inputs. The subminor had a continuous flow all through the season with a flow of 4 to 5 cusecs to a lower area which was itself never short of water. Farmers could always see water flowing past their outlets, even when they were not receiving it.

To the best of my knowledge and belief, none of the controls with which the comparisons were made received the same special treatment of negotiation, guaranteed water supply, or arrangements for credit and input supply.

In the light of these procedures and other evidence let us now look at each of the four findings.

Acceptance by cultivators. No indication is given of how the 'general acceptance' was assessed, nor whether this included the two trial subchaks which were rejected, but it is scarcely surprising if the Koliary outlet cultivators accepted assurances of a guaranteed water supply, credit and inputs. Indeed, the benefits from these could override other inconveniences if they were a necessary price to pay. Had there been negative attitudes to subdivision and rotation, they could have been obscured by welcome for unprecedented access to credit and other services. In sum, this finding cannot be said to have been established.

Time taken for irrigating the entire outlet command was 5 to 14 days as against 20 to 45 days for normal outlets without subchaks. The figures cited in the finding are not those of the report. The comparison of 5 to 14 days with 20 to 45 days looks decisive and impressive. However: if the averages for all the chaks are taken, the average for trials was 15 days and for controls 17 days, hardly a decisive difference; the 5 to 14 figure for trials is reached by accepting the two better performing trial chaks, which were reported to take 5 and 14 days respectively, and rejecting the trial chak on HBP which was reported to have taken 25 days. No control chaks were rejected; the 20–45 days figure for controls is more difficult to understand. The report gives a range of 6 to 46. Four of the controls, taking 6, 6, 8 and 10 days respectively were said to have had heavy rainfall which shortened their irrigation. This rainfall was not reported to have affected any of the trials. But even if these four control chaks are eliminated on the grounds of heavy rainfall which they alone received, the controls remaining took 7, 8, 16, 17, 22, 27 and 46 days respectively, giving a range of 7 to 46, not 20 to 45.

Thus, instead of 5 to 14 for trials and 20 to 45 for controls, the correct comparison would appear to be 5 to 25 for trials and 6 or 7 to 46 for controls. The figures officially quoted as 'findings' are difficult to explain.

A more plausible interpretation is that time taken to irrigate the entire outlet command was a function of position on the main system and of the water supply. This is suggested, for example, by comparing the two trials with head locations on the MRP with the MRP control which had a comparable head location. The performance was closely similar, as follows:

Saja (trial)	71.2ha in 14 days = 5.1ha/day
Koliary (trial)	23.6ha in 5 days = 4.7ha/day
Dy 10/MMC (control)	42.3ha in 8 days = 5.3ha/day[1]

Variation in yield within an outlet command was less when it was divided into smaller units. For variance of yield within an outlet command, the Koliary outlet was compared with the 11 controls.[1] The variance in yield of the Koliary outlet was arrived at by comparing the average yields of the three subchaks (lowest subchak 87, highest subchak 120, with 100 average). For the 11 control outlets, however, variance was obtained by comparing average yields for the head areas of all 11 outlets with average yields for all their tail areas (tail areas 68, head areas 127, with 100 average). Arrived at differently, the Koliary and control figures are not comparable, and no conclusions can be drawn.

With smaller subchaks yields were 70 to 137 per cent higher compared to the normal outlets. The 70 to 137 per cent higher yields appear to be based on a comparison of yields on the Koliary outlet with respectively the 11 controls (Koliary was 70 per cent higher) and the 57 outlets on both systems which were subject to a major crop-cutting survey (Koliary was 137 per cent higher). The question is whether these higher yields could be attributed to smaller subchaks and rotations.

Some relevant data for the controls are in Table 5.3.

The WAPCOS Report (1980, p26) while conceding that 'The increased yield on Koliary might be partly due to the larger input of fertilizers' goes on to assert 'but mainly it was due to reducing the command into smaller irrigation units'. But such a conclusion could only follow from a careful analysis controlling for different variables. The surprise is that the Koliary outlet, with its special water supply, HYVs and inputs, achieved only 2.065 tons/ha and not more. Some other factors may have held down yields. A perverse possibility cannot be excluded: that, far from enhancing yields, subdivision and rotation actually depressed them.

This review of the evidence, concludes that the four findings about the good effects of subdivision of chaks and rotation of water between subchaks were unfounded. The larger survey of 57 chaks showed sharp gradients of declining

Table 5.3 *Trial and control inputs and yields*

Input	*11 control outlets without subchaks*		*Koliary outlet with subchaks*
	MRP	HBP	
Irrigation (mm)	395	171	311.5
Percentage HYV	62	Nil	100
Farmyard manure kg/ac (*sic*)	1854	890	1590
Urea, phosphate, potash and others kg/ac (*sic*)	43	23	154
Yield of rice kg/ha (*sic*)	1225	1185	2065

yields as one passed from head through middle to tail along canals, distributaries, and minors, and within outlets (WAPCOs, 1980; Lenton, 1983) and indicated location on the main system as a powerful explanation of differences in yield and other indicators of performance. When similar but rigorous research on subdivision and rotation was conducted by Wickham and others in the Philippines in the early 1970s (Wickham et al, 1974; Lazaro and Wickham, 1976; Wickham and Valera, 1978) the yield differences with subdivision and rotation were not significant compared with the control. The researchers went straight on to infer that location on the main system and water deliveries were more important. Through painstaking, good research, they identified main system management, and not subdivision and rotation, as the priority. It was tragic that India was not equally well served, and that, in contrast, the Government of India and the World Bank were pointed, at great expense, in a direction which the research did not justify, and away from main system management as the priority.

The research, it seems, was so focused on subdivision and rotation between subchaks that other explanations or findings were largely excluded. Interesting suggestions about water use efficiency were largely overlooked. The investigation seems to have set out from the start not to learn but to 'succeed'; not, that is, to conduct a scientific investigation of causality, but to show that the chosen intervention made things better. Perhaps it would be fairer to describe it as a privileged pilot project rather than a research study. As a research study, it failed by succeeding.

Islands of Salvation

The 'pilot project syndrome' is well known in rural development. A small area is chosen for its favourable conditions, and an experiment or trial undertaken with special inputs, management, care and attention. It 'succeeds'; lessons are believed to have been learnt; and directives are issued for the approach to be replicated. But the special conditions which enabled the experiment or trial to do well are not reproduced, nor indeed reproducable, and the innovation fails to spread. As with the Koliary chak above, an island of salvation is created which cannot be multiplied into an archipelago, let alone a land mass.

To try to understand this phenomenon, let us examine two other examples: the Mohini Water Cooperative Society near Surat in Gujarat; and the Naurangdeshar Canal System of the Rajasthan Canal Project.

Mohini[2]

Water cooperatives which purchase water in bulk and then distribute it among their members are widely regarded as a promising development deserving support and spread. The India's Sixth Five-Year Plan had this to say:

> Already Gujarat has made an effort in forming farmers cooperative (*sic*) for distribution of water. They take water in bulk from the irrigation department and distribute it amongst the members. This has resulted in better efficiency in use of water. (GOI, 1981, p157)

The Water Technology Centre Study of Mahi-Kadana devoted a whole chapter to irrigation cooperatives and proposed their introduction (WTC, 1983, pp288–297). A senior official, K. M. Dave, also wrote (1983, p127) that:

> The benefits of such water cooperatives have now come to be recognised by one and all. It is a very powerful tool for optimising the returns from the irrigation projects. Moreover, such water cooperatives can also help in bringing out a total change in the status and living conditions of the beneficiaries.

In the first half of the 1980s, water cooperatives, in the plural, were part of the common currency of discussion about farmers' organization on canal irrigation in India, and in 1986 one authority wrote that:

> it has been accepted at all levels that the Water Co-operative offers the best solution for economical and efficient water use and increased productivity (Shah, 1986, p9).

The idea of water cooperatives is not new: they have been proposed in Maharashtra for at least two and a half decades. The Maharashtra State Irrigation Commission recommended in 1962 that the distribution of canal water should be entrusted to cooperative societies of the irrigators. But attempts to trace back the various favourable views about water cooperatives to actual institutions operating on the ground always lead to the same place. Unlike other sources which mentioned cooperatives in the plural, the recommendations of the 1980 Conference on Warabandi (Singh, 1981) were careful to mention only a singular water cooperative in Gujarat as an example of farmers' organizations. This appears accurate, for again and again references trace back to the same institution, the Mohini Water Cooperative Society or Mohini for short. In the WTC Report it is cited as 'the first successful irrigation cooperative in Gujarat' (WTC, 1983, p291). It is described by V. S. Sinha (1983), Area Development Commissioner, Surat, by Pant and Verma (1983, pp23–4, citing Sinha), by K. M. Dave, Superintending Engineer and Officer on Special Duty (1983), and by R. K. Patil. As Dave put it, Mohini 'has made tremendous all round impact and its name and fame have spread not only in the entire state but also in the entire irrigation sector of this country at large' (1983, p133). It was indeed the source of the statement in the Sixth Five-Year Plan (Patil and Datye, 1986, p2).

This cooperative which has so influenced thinking has a good record. Founded in 1978 it was assigned a CCA of about 450 hectares on the Bhestan minor of the Kakrapar canal system, and began with 145 members. Over the years its membership, area and intensity of irrigation grew. The government wholesaled water at

30p per 10,000 litres to the society which then sold it to its members on a per acre basis with a substantial margin. Its members benefited and the society became an instant success (Patil and Datye, 1986, p4).

This success, and these benefits, were, though, based on special and privileged conditions. The cooperative had strong leadership. Seventy per cent of members were Patels, reputed to be commercially astute. Location was favourable: the society is close to Surat city, a national highway, and the Chalthon Sugar Mill. There was special government help: at the outset, the distribution network of canals was renovated at government expense, additional outlets to the minor were added, vulnerable reaches even of water courses were lined, and 'all preliminary procedures were set up for smooth interaction with local officers of Government for all matters' (Dave, 1983, p132).

For the first three years the state government provided a manager, a supervisor, and two clerks and agreed to reimburse any net loss.

There was also exceptional access to high-level staff, with solutions to problems worked out at the deputy executive engineer and executive engineer (EE) levels (Shah, 1986, p13). Although the designed crop pattern limited the area of the profitable crop of sugarcane to only 18 per cent, the actual area in Mohini Command exceeded 85 per cent (Patil and Datye, 1986, p4).

When a high-powered task force visited the Kakrapar Command in 1983, the cooperative visited was almost certainly Mohini. The task force chairman, S. P. Mukerji, the Secretary of Agriculture, wrote:

> Much has been talked about the water cooperatives in this Command. Unfortunately, we were not very much impressed by our visit and discussions with the members of a water cooperative society. The cooperative covers only 440 hectares around a sugar mill and most of the area has been brought under sugarcane... The cooperative has been a method by these farmers to obtain water in bulk at a concessional rate and distribute the same amongst the members for production of sugarcane under the overall protective umbrella and support of the local sugar mill. (MOA, 1984, p64)

The low water rate and the heavy reliance on sugarcane gave both society and farmers favourable financial margins. Perhaps, most important of all, before the society was formed, irregular water supplies from the main system adversely affected farming, but with the society a reliable and adequate supply was assured. Indeed, it would have been an unusually imprudent EE or Deputy EE who did not go to pains to ensure a good water supply to an area which attracted such frequent visitors and so much national attention.

An impression easily grew that there were other functioning water cooperatives like Mohini. V. S. Sinha (1984, p264) reported the registration of a second cooperative, the Dhanori Changa Piyat Sahakari Mandli, and a demand in 1982 for 37 more. In 1986, 21 water cooperative societies were reported to have been registered in the Ukai-Kakrapar Command Area, and two were said to have started functioning in 1985 (Shah, 1986, p14). But one authority, while supporting the propagation of irrigation cooperatives, observed that the Maharashtra Government had pursued the issue of handing over water to cooperative bodies of irrigators for 30 years but 'still full success is not in the offing' (Gandhi, 1985, p14); and others were more directly sceptical. Patil and Datye (1986, p2) wrote that the Mohini Society 'has not been replicated and 20 societies registered in the vicinity are virtually defunct'. That this could be so is scarcely surprising. The location and history of Mohini make it a classical case of the pampered pet project, where each special measure reduces replicability. The levels of subsidy, of sugarcane cultivation, of high-level official concern for success, and especially of assured water supply, were not easy to repeat. Mohini, much visited and much mentioned, generated a myth of water cooperatives in Gujarat. But it probably has been, and may well remain, alone, an island of salvation.

In its section on Command Area Development, the Seventh Five-Year Plan has farmers cooperatives again in the plural, assumes replicability and advocates their spread:

> The farmers' associations and cooperatives established in some parts of the country have been successful in the equitable distribution of water among their members, the bulk of the water supply being given by the Irrigation Department, to such cooperatives. This must be extended to other areas. (GOI, 1985, pII:82)

Outside India, Mohini has been generalized to Gujarat State as a whole. One international authority wrote in 1986:

> In Gujarat State in India, the irrigation agency sells water volumetrically in bulk to cooperatives, which distribute it and collect fees from their members (Repetto, 1986, p33)

The myth of water cooperatives in Gujarat has, it seems, an ability to spread not shared by the institution itself. It is believed in Washington as well as New Delhi. Just how immortal the myth is will be shown in the Eighth Plan, to be awaited with keen interest.

Naurangdeshar

In 1980 a long-term improved water management study was taken up in an area of about 28,000ha under the Naurangdeshar Distributary of the Rajasthan Canal (Bithu, 1983). Water flows and deliveries were measured and monitored at 21 main take-off points on distributaries and minors and at 20 tailend points on the minors and subminors. Irrigation demonstration fields were established. Special 0 and M grants were made to improve operation and maintenance. Irrigators in the area were occasionally contacted by water management staff to assess equitability of irrigation water distribution and crop production.

The trial area did better than a control area. Cropping intensity was higher in the trial area – 66 per cent against 47. More wheat, mustard and cotton were grown, while gram, the lower risk lower value crop, was grown more in the control. The programme in the Naurangdeshar distributary system was said to be widely accepted and acclaimed by the irrigators.

The better performance of the trial area was, however, at the expense of the rest of the system. Water deliveries to the Rajasthan canal from Punjab were not regular, and fluctuations in canal water deliveries were 'occasioned by the unpredictable monsoon and lack of systems approach by the interstate irrigation promoters' (Bithu, 1983, p74). Efforts were made to ensure timely and adequate supplies from Punjab, but 'in the meantime certainty of water delivery in Naurangdeshar distributary system [had] been ensured through preferential running of the system'. In his analysis, Bithu notes the connection between the trial performance and this preferential treatment, and concludes that 'since preferential running of all systems on demand is not possible unless we ensure adequate and assured supplies from Punjab, its extension to other systems is limited for sometime' (Bithu, 1983, p77). The point can be taken further: if one part of the system receives guaranteed adequate and timely water when overall supplies are variable and unreliable, then untimeliness and inadequacy are amplified in other parts of the system. Naurangdeshar's performance must have had costs elsewhere. It is perhaps unsurprising that there was a general consensus among farmers that the system should be extended. Farmers will always go for a preferential water supply.

Learning and Mislearning

These cases throw light on learning and mislearning about canal irrigation, and point to pitfalls. Four further observations can be made.

First, areas chosen for action research or pilot projects are often specially favoured. Like the Koliary chak, they may be in the head reaches. Like both Koliary and Mohini, they may be close to administrative headquarters. Conversely, controls are often in less-favoured areas, as happened with the MRP and HRP controls.

Second, special attention makes it difficult to draw practical conclusions. One reason is multiple causality. If there are several interventions, and yields are higher, then there are several explanations. The higher yields on the Koliary outlet could be attributed to combinations of special supplies of the following: credit, HYV seeds, fertilizer, pesticides, extension and water. Another reason is privileged access to water at the cost of other parts of the system. The Koliary outlet and the Naurangdeshar Distributary were both given specially adequate and reliable water supplies from larger systems where other reaches already had inadequate and unreliable supplies. In this, they were not unusual. Again and again, when an initiative – whether described as action research, or pilot project, or experiment – is probed, it emerges that it has been favoured for water. This may be a deliberate part of the treatment, as with Koliary and Naurangdeshar; or it may be unintended, where system managers give a better than usual supply to a part of their system where they know investigations are taking place.

Such a supply usually has costs elsewhere. Digby Bevan (personal communication) visiting a warabandi pilot project in Andhra Pradesh in 1980 found, through his initial questioning, that the farmers were happy and everything appeared to be running smoothly; but further investigations revealed that the pilot scheme was getting preferential treatment and receiving more water than needed while the supply in the larger area of which the scheme was part was completely erratic. P. S. Rao (personal communication) visiting a pilot project for rotational water supplies on part of the Periyar Vaigai Project in Tamil Nadu went further down the minor and found farmers who complained that they were getting less water than before as a result of the pilot project. Anthony Bottrall (1983, p106) found that farmers in a village immediately downstream of a pilot (showpiece) watercourse were receiving very little water because extra supplies were being diverted to the pilot watercourse in order to demonstrate its 'success'. Similarly low concentrations of wheat, mustard and cotton on the Rajasthan Canal control, and its higher concentrations of gram, probably owed something to the adverse effects of the privileged water supply of the Naurangdeshar Distributary.

So, wherever research or a pilot project is undertaken and 'success' reported, whether it is warabandi, on-farm development, canal lining, farmers' organization, rehabilitation, the management of minors or distributaries or something else, costs to other parts of the system must be assessed. The question is whether water to the special area means supplies to others, which are smaller, are less timely and less predictable. Islands of salvation often draw resources to themselves and deprive others. Many successes are really failures. Nor are they replicable unless water supplies on the main system can be managed to provide a similar supply elsewhere. Once again, analysis points to the priority of main system management.

Third, the normal process of learning from 'islands of salvation' can mislead. The biases of rural development tourism (Chambers, 1983, pp10–25) apply. Short visits by officials and researchers give rise to insights of uniform superficiality. The same farmers are met by a succession of visitors and they tell them the same things, while others are not met. What the farmers say can be slanted, sometimes false. A social anthropologist in South India once sat through a whole morning during which officials put farmers through their lines, rehearsing them in how to answer questions expected from a senior officer who was coming the next day. Then visitors are taken to the best places, and do not have time, even if they wish, to probe multiple causation, to question biases in what they see or are told, or to perceive costs to other places which offset the benefits they are shown. With any policy – CADA, OFD, 8 hectare chaks, warabandi – rural development tourism and the well-prepared visit impede learning and distort perceptions. Visitors depart to their conferences and committees where error reinforces error as they repeat to each other their common misperceptions. As with the Mohini Cooperative, a belief can gain currency that an approach is replicable and should be included in policy and plans. Busy politicians and policy makers need good ideas to seize on and push, but all too often these are based on and support self-sustaining myths.

Truth is elusive, and as Oscar Wilde said, never pure and rarely simple. To get closer to it requires awareness of these traps, and commitment to good research.

Reflections on Research

Good research is difficult. It is easiest to do professionally acceptable research by sticking to narrow topics. Those who branch out into more complex investigations like action research face methodological problems and will be open to criticism from colleagues. Yet these risks have to be accepted if gap and linkage subjects are to be opened up and if fuller and more balanced understanding is to help improve performance.

Two sets of considerations appear important here. First, what determines what research will be done, and in particular what deters research on gaps and linkages. Second, what approaches and qualities are required from those who undertake it.

Determinants of research

The many determinants of research include fashions and funding, who is available, and researchability.

Worldwide, rural research tends to follow the latest fashions and priorities of funding agencies, and these often follow the latest programmes of government. Canal irrigation in India is no exception. Thus, on Mahi-Kadana, Asopa and Tripathy studied the Command Area Development programme soon after it had come in; the WMSP team operated mainly below the outlet, which was also where government programmes (OFD, farmers' organization and warabandi) had concentrated; and the WTC research, in its objective, was concerned with total resource use, moving in the direction of mounting official concern with poor canal irrigation system performance. The WAPCOS research was even more directly linked with policy, intended as it was to test the benefits of a proposed large-scale programme.

But good research does not necessarily have to be linked to immediate policy or innovation. Investigations which simply (or not so simply) show what is happening to water, crops and people, have much to contribute. Those organizations, whether government or private, which fund research, do well to achieve a balance between studies which monitor and assess current performance and programmes, those which more directly investigate future opportunities, and those which open up gaps and linkages. The tendency is for current programmes to be studied, and for gaps and linkages to remain unresearched, as blind spots.

What research is undertaken is also determined by who is available. Research is often thought to be led by demand. Government, public corporations, universities and foundations determine priorities and then fund researchers to follow them.

This is only part of the truth. What can be done depends also on who is available and on their interests and skills. Research on canal irrigation in South Asia has until recently been conducted almost exclusively by physical and biological scientists. In contrast, in India in the mid-1980s, the Indian sociologists committed to field research on canal irrigation could still be numbered on the fingers of one hand. The neglect of the human and managerial domain can be attributed more to a lack of supply – of researchers – than to lack of support for them to conduct research. In this respect, the WTC study did not muster a sociologist, and, perhaps as a consequence, did not deal with farmers' actual organization or distribution below the outlet. In contrast, the Asopa/Tripathi and WMSP studies were exceptional in the attention they gave to social aspects of irrigation.

To a damaging degree, researchability also determines what is researched and so what is known. Inconvenience deters senior researchers from sustained field measurements. Water flows are anyway difficult to measure accurately. Flows at night, that most inconvenient time, remain largely a black box. Or again, corruption can affect system performance, but is a sensitive subject which cannot be explored by a quick field visit, and even less by stating that it is to be investigated. It is not surprising that the Mahi-Kadana studies did not go in any detail into whether or not payments were made by farmers in order to obtain water indents, and how this hassle and cost factor might have influenced their irrigation decisions. It is far easier for an agricultural economist to investigate input or farmgate prices than to assess the significance of a hassle factor in deterring farmers from applying for water, or for an agricultural engineer to record frequency of damage to watercourse structures than to measure water flows at night. Moreover, for gap and linkage subjects, there are often no clearly established methods of inquiry. How, for example, does one assess the knowledge and expectations of farmers regarding the water they will receive from the main system, and how this affects their behaviour? Crucial though this may be for farmer's behaviour, it is not studied or reported on. Some difficult subjects are all the more important because less is known about them.

Approaches

This leads straight to the approaches of researchers. It is easy to say what ought to be done, but harder to do it. Nevertheless, three approaches or qualities can help to offset biases, to explore gaps and linkages and to achieve balanced insight. These are an open learning process, a concern for understanding and truth, and introspection.

An open learning process approach to research is often made difficult by funding and methods. To obtain funding, a research design is often called for. Preparing it can be salutary, injecting realism into plans. But a blueprint mentality and a rigid method can damage and constrict. One great drawback of research by blueprint, on familiar topics using well-worn methods, is what it excludes. Preset questionnaires are barriers to learning. Standard surveys, in whatever subject, provide standard information and exclude the unexpected. When method is the master, gaps, linkages and serendipity stay in the dark. Standard multidisciplinary research can generate islands of information between which bridges cannot be built.

On the other hand, inquisitiveness, observation, and an eagerness to learn from farmers and others can open up unsuspected topics. For example, the WMSP finding on Mahi-Kadana that farmers were prepared to pay seven to nine times as much for lift irrigation water as the official water rate for canal water might have suggested a new research agenda with new policy implications.

There is no one recipe for an open learning process, and more depends on attitudes than on planning. But one measure can be recommended: not committing all research resources at the start of an investigation. If spare capacity is held in reserve, new questions can be followed up as and when they are identified. This is not to argue against careful measurements sustained over time. It is to argue that they are unlikely to be enough in themselves, and that qualitative investigations, often with improvised methods, have much to contribute if gaps, linkages and serendipity are to be explored as they need to be.

It seems obvious that concern for understanding and truth should drive every researcher. Yet routine performance of a method and a stereotyped report often seem to reflect concern more for proper observance of ritual than for new knowledge. One omission in most, perhaps all, disciplines is self-critical publication by researchers of defects in their methods. When researchers honestly present the errors and limitations of their research, it gains in credibility, and the confessions contribute to future methodology. Research is not a ritual, still less an exercise in producing a predetermined right answer. It is, or should be, an exploration of unknown terrain where one does not know what will be found. Canal irrigation is so shrouded in mists of misinformation that it needs many more who keep their eyes open and report what they see. Action research is thick with traps (Chambers and Lenton, 1981), and temptations to make pilot projects islands of salvation are hard to resist. The best service is done by those who strive not for correct appearances but for true insight.

Finally, observers do not often observe themselves, or assess the limits of their vision. Little research is conducted on research. Yet so often researchers see what they are trained to see, ask what they are trained to ask, measure what they are trained to measure, and conclude what they are trained to conclude. This has its value, within limits. But many of the more important aspects of canal irrigation are simply not covered in textbooks or training. Though knowledgeable and competent in their subjects, well-trained professionals miss much that matters. Normal professionalism is not enough. Few would perhaps disagree. But to extend normal professionalism to cover gaps and linkages is hard. A first step is awareness of one's conditioning and biases. It is easy to be deterred from exploring new domains, hidden linkages, and gap subjects, not just by inconvenience or risk, but also because vision is confined and directed by the ruts and reflexes of disciplines. Introspection is one way of removing such professional blinkers, gaining a wider view and offsetting biases.

Notes

1 It was also compared with the 57 general outlets, for which the same method of analysis was used as for the 11 controls (giving low 70, high 117, average 100).

2 I am grateful to R. K. Patil for personal communications derived from his field work which have shed much light on Mohini and water cooperatives. See also Patil references. Responsibility for the views expressed is, however, mine.

Reversals, Institutions and Change

Robert Chambers

Farmer first and TOT

The new behaviours and attitudes presented by the contributors to this book conflict with much normal professionalism and with much normal bureaucracy. Normal professional training and values are deeply embedded in the transfer-of-technology (TOT) mode, with scientists deciding research priorities, generating technology and passing it to extension agents to transfer to farmers. Normal bureaucracy is hierarchical and centralizes, standardizes and simplifies. When the two combine, as they do in large organizations, whether agricultural universities, international agricultural research centres, or national agricultural research systems (NARSs), they have an impressive capacity to reproduce themselves and to resist change.

But to serve well the resource-poor farm families of the third – complex, diverse and risk-prone – agriculture with which much of this book has been concerned, requires these 'normal' tendencies to be reversed: for farmers' analysis to be the basis of most research priorities, for farmers to experiment and evaluate, for scientists to learn from and with them; and for research and services to farmers to be decentralized, differentiated and versatile.

The difficulty of effecting major changes and reversals in large organizations underlines the importance of seeing what changes of behaviour and attitude are required, what institutional conditions are necessary for them to be sustained and spread, and how these might be achieved. To do this, we need to outline in more detail the contrast between TOT and the farmer-first approach and methods represented in this book (see Table 6.1).

With farmer first, the main objective is not to transfer known technology, but to empower farmers to learn, adapt and do better; analysis is not by outsiders – scientists, extensionists or NGO workers – on their own but by farmers and by farmers assisted by outsiders; the primary location for research and development

---

Reprinted from Chambers R. 1989. Reversals, institutions and change. In Chambers R, Pacey A and Thrupp L A (eds) *Farmer First*. IT Publications, London, Chapter 4.4, pp181–195.

Table 6.1 *Transfer of technology and farmer-first compared*

	TOT	*FF*
Main objective	Transfer technology	Empower farmers
Analysis of needs and priorities by	Outsiders	Farmers assisted by outsiders
Primary R&D location	Experiment station, laboratory, greenhouse	Farmers' fields and conditions
Transferred by outsiders to farmers	Precepts Messages Package of practices	Principles Methods Basket of choices
The 'menu'	Fixed	À la carte

(R&D) is not the experiment station, laboratory or greenhouse, necessary though they are for some purposes, but farmers' fields and conditions; what is transferred by outsiders to farmers is not precepts but principles, not messages but methods, not a package of practices to be adopted but a basket of choices from which to select. The menu, in short, is not fixed or table d'hôte, but à la carte and the menu itself is a response to farmers' needs articulated by them. All this demands changes in activities and roles.

Farmer-first Activities and Roles

Contributions to this book show farmers carrying out or participating in various activities which in the TOT mode are conducted only by scientists. Three of these, again and again, are analysis, choice and experiment. To support farmers in these activities generates and requires new roles for outsiders:

Farmers' activities	*New roles for outsiders*
analysis	convenor, catalyst, adviser
choice	searcher, supplier, travel agent
experiment	supporter, consultant

What these activities and roles entail can be illustrated by contributions to this book, supported by other sources.

(i) Analysis. Analysis by farmers takes many forms and can be promoted in many ways, involving outsiders to different degrees. In the examples in this book an outsider has often played a role, whether as questioner, convenor of a group, stimulator of discussion or catalyst whose presence speeds up the process.

Analysis can be part of or generated by the use of a method. Some examples are:

- open interviews and iterative group conversations (Floquet, 1989);
- ethnohistory and ethnobiography (the biography of a crop, or of a person's experience of a crop, an historical analysis of the experience of a community etc.) (Box, 1987);
- inspection and discussion: visiting trial sites, observing innovations, field days, and visits by farmers to research stations when they observe and discuss (Ashby et al, 1987);
- visual aids to analysis: seasonal and other diagramming (Conway, 1985), aerial photographs (Carson, 1987), systems diagramming on a board (Lightfoot et al, 1987), other uses of diagrams with and by farmers and communities (Kabutha and Ford, 1988; McCracken, 1988) and drawing maps (Gupta, 1987a, b);
- eliciting clients' criteria and preferences, where individuals or groups (women, men, farmers etc.) articulate their reasons for preferences, and then rank items according to them (Ashby et al, 1987; Chambers, 1988);
- key questions and approaches to questioning: 'ways in' or 'points of entry' such as 'What would a desirable variety look like to you?' (Ashby et al, 1987, p27), 'What would you like your landscape to look like in the future?' (Rocheleau et al, 1985), 'When you were a boy, what was the oldest variety of (a particular crop) that you knew about?' (Box, 1987) and 'Comparing agriculture practiced at the time of your father and grandfather with the agriculture practiced by you today, what are the major changes that have occurred?' (Gubbels, 1988);
- contrast analysis, where groups or individuals are asked to explain the contrasting conditions or behaviour of others, thus setting a frame of reference before analysing their own (Gupta, 1987a, b)
- sequences of meetings and visits (Rocheleau et al, 1985; Mathema and Galt, 1987; Lightfoot et al, 1987; Repulda et al, 1987; Norman et al, 1988);
- innovator workshops where farmer innovators meet to discuss their new practices (Abedin and Haque, 1987; Ashby et al, 1987).

The role of the outsider is to elicit, encourage, facilitate and promote analysis by farmers, providing where necessary the stimulus, the occasion and the incentive for meetings and discussions. The outsider can take part, but does not dominate. Farmers' own analysis, criteria and priorities come first. Requests are generated for outsiders to search for what farmers want and need, and to provide them with choices or ideas for experiments to solve a problem or exploit an opportunity (Lightfoot et al, 1987; Repulda et al, 1987).

(ii) Choice. Choice by farmers is prominent in the farmer-first paradigm. It has two aspects. First, farmers' analysis generates an agenda of requests for information and material. Second, farmers need a range of choice, so that they can pick and choose to suit their conditions, extend their repertoire and enhance their adaptability. Norman et al note 'the technology assessment process in which a wide range of options are presented to a large number of volunteer farmers' (1988, p141). To find and present variety and choices to farmers is largely a task for outsiders. Some examples are:

- providing farmers with varied genetic materials to test and appraise (Ashby et al, 1987; Norman et al, 1988);
- planting a variety of lines or species, to be followed by 'wait-and-see and pick-and-choose';
- issuing mini-kits of seeds and fertilizers to farmers for them to try out in various combinations;
- requiring nurseries, as with forestry in Kenya, to plant and provide a range of species, including a preponderance of indigenous species;
- transferring genetic material between regions, countries and continents, especially of non-cereal plants (multi-purpose trees, shrubs, grasses, vining plants, root crops etc.) and livestock;
- transferring indigenous technical knowledge and practices between farmers in different regions;
- enabling farmers to travel, visit, see and learn for themselves the farming practices of others.

The role of the outsider, whether scientist, extensionist, or NGO worker, is to search for and supply the species, varieties, treatments, cultural practices, scientific principles or combinations of these which fit and meet farmers' requests and needs. It may also be that of travel agent or tour operator, to arrange for farmers to visit research stations, other farmers, or other regions, to learn from other farmers and scientists and to widen their experience and options.

(iii) Experimenting. Experimenting by farmers has long been under-perceived. The professional world has been slow to recognize farmers' experimental inclinations and abilities (but see Johnson, 1972; Richards, 1985; Rhoades, 1987). Rhoades and Bebbington (1988) have identified three reasons why farmers experiment: to satisfy curiosity; to solve problems; and to adapt technology. As we have seen, their farming is both performance (Richards, 1987) and in a sense a continuous experiment: Hossain et al point out that farmers in Bangladesh are continually changing their cropping patterns (1987, p35) and Juma puts it that 'a farmer is a person who experiments constantly because he is constantly moving into the unknown' (1987, p34).

In the farmer-first approach, it is not packages of technology that are provided to farmers, but genetic material, principles, practices and methods for them to test and use. Genetic material can take many forms and may come from nearby, from other regions, or from other countries or continents. Similarly, principles can originate from different sources: in West Africa, the principle of alley cropping was taken from the research station and was adapted and experimented with by farmers (Sumberg and Okali, 1988); the principle of diffused light to inhibit potato sprouting in store originated with farmers in Kenya and was spread internationally and laterally to other farmers in many countries, who made their own applications with local materials to fit local farm architecture (Rhoades, 1987). Experimental principles and methods suitable for their conditions and needs can also be provided to farmers to improve their investigations and innovations (Bunch, 1985, 1987).

Farmers' experiments are, then, encouraged and supported by outsiders. This is close to Biggs' collegiate mode of farmer–scientist *interaction*. Farmers take part in design (Fernandez and Salvatierra, 1987), determine management conditions and implement and evaluate the experiments. They 'own' the experiments and the outsiders provide support and advice.

Evaluation of experiments is also by farmers and continuous. An authoritative World Bank publication (Casley and Kumar, 1987, p116) has pointed out that it is often assumed that illiterate, tradition-bound farmers cannot assess the dynamics of change, but that their knowledge and judgments are in many instances more accurate than those of project staff. One of D. M. Maurya's criteria for assessing a line given to a farmer to try is whether other farmers ask for seed (personal communication). It is farmers' judgements, interest and adoption that count.

Stimulating, servicing and supporting these farmers' activities – analysis, choice and experiment – requires reversals of normal and expected roles on the part of outsiders, be they scientists, extensionists or workers in NGOs. This does not mean that they have to be purely passive catalysts. It would be as absurd for their ideas and knowledge not to be brought into play, as it has been for those of farmers to be neglected. In raising questions, in providing tools for analysis, in presenting what they already know to be feasible and available choices, and in supporting and advising on farmers' experiments, they have a part to play. But their role is not that of teacher, of the bearer of superior modern technology, of the person who knows what is good for others better than they know for themselves. It is neither the role of traditional agricultural extension, nor that of normal agricultural science. An open, learning process approach is indicated, of a sort encouraged neither by the content of university curricula nor by the hierarchy and style of government bureaucracies.

For these changes and reversals of role to occur on any scale is not easy. It requires resolute changes in institutions, in incentives and in methods and interactions.

Institutional Change

Unfortunately, normal bureaucracy tends to centralize, standardize and simplify, and agricultural research and extension are no exceptions. They fit badly, therefore, with the conditions of resource-poor farm families, with their geographical scatter, heterogeneity and complexity within any farm and farm household. In resource-rich areas of industrial and Green Revolution agriculture, production has been raised through packages, with the environment managed and controlled to fit the genotype. The third agriculture, being complex, diverse and risk-prone, requires the reverse, with searches for genotypes to fit environments. In industrial and Green Revolution agriculture, higher production has come from intensification of inputs and simplification and standardization of practices; in the third agriculture, it comes more from diversifying enterprises and multiplying linkages. Green Revolution agriculture has been convergent, evolving towards common practices; the third agriculture often needs to be divergent, evolving towards a greater variety of differing enterprises and practices.

At first sight, then, the farmer-first approach appears incompatible with normal bureaucracy. But as contributors to this book have shown, reversals in government research organizations, though difficult to start and to sustain, are not impossible. Some contributors were working in special projects linked with NARSs; others were working in more normal conditions, as with the innovator workshops in Bangladesh (Abedin and Haque, 1987) and the distribution to farmers of advanced lines of rice in India (Maurya and Bottrall, 1987).

For the future, to achieve farmer-first reversals in national bureaucracies, especially NARSs, three aspects of management merit special attention: decentralization and resources; search and supply; and incentives.

(i) Decentralization and resources. Central controls need loosening if local actions are to fit diverse conditions. Centralized permissions for expenditures constrain flexibility. Centrally coordinated trials limit discretion and the ability to serve local priorities. When resources such as transport and money for travel are scarce, local discretion and control become more important than ever. The essence of farmer-first approaches is to serve and support local diversity, with a reversal of demands on staff, the demands to come from farmers below more than from seniors above.

Decentralization is difficult in normal bureaucracies. Central accountants fear loss of control over expenditures. Central officials fear loss of power and prestige. Reports are harder to collate and present, and work harder to supervise, when activities are varied. Methods are needed, perhaps easier now with microcomputers, for valuing local diversity in staff activities in place of counting reported achievements of standard targets. For NARSs, the practical implications are to devolve resources and discretion more to the local level.

Freedom and means for staff to visit and spend time with farmers are crucial. For travel, something can usually be done quite simply. In the joint trek in Nepal, scientists walk together for days (Mathema and Galt, 1987). Foot, bicycle, horse and public transport can, variously, be used. For cost-effectiveness, though, other means of travel can be important, especially when distances are great and environments diverse. Unfortunately, access to transport and permission to use it are frequent problems, though less so with foreign-funded programmes. Travel and allowances can be high-profile privileges for which staff compete, jealously guarded and sparingly allocated by directors of institutes and heads of units. Worse, when revenue shortfalls or national policy reforms force cuts in recurrent budgets, staff are usually protected and it is other votes that suffer. Fuel, vehicles and nights out allowances are favourite victims. In Zambia, the Ministry of Agriculture's vote for petrol and maintenance had been reduced by 1980 to only one fifth of its 1973 level despite an increase in vehicles and staff (ILO, 1981, pxxvi). Scientists can usually work with farmers close to their research stations and residences; but without hassle-free and adequate access to means for travel, it is difficult for them to work regularly and well with others further afield.

(ii) Search and supply. Search is neglected and rarely rewarded as a professional activity. This includes search for farmer-innovators and experimenters, for genetic material, and for principles, practices and technologies, whether locally, regionally, nationally or internationally.

Search is basic for meeting farmers' needs and widening their choices. In complex, diverse and risk-prone agriculture, what farmers want and need often differs from the simplifications of centrally planned priorities. Agricultural research and extension have, for example, a tendency to specialize on single commodities. But farmers' analysis will often specify a non-commodity need, such as multi-purpose trees for agroforestry, or a rapidly vining legume to suppress weeds, or a range of vegetable seeds, or means to create, improve and exploit micro-environments, or technology for harvesting water, capturing and concentrating soil, or improving the supply of plant nutrients. As a result of past neglect, the potential for search and supply of such varied material and technologies seems still very large.

Search and supply have institutional implications. These include that grassroots extension staff and scientists have resources and are rewarded, for finding farmers' innovations and experiments and for stimulating and articulating realistic demand from farmers; and an ability of national and international agricultural research systems to respond with supplies of genetic material, principles and methods.

These reversals face two major obstacles. First, extensionists and scientists may not be rewarded for raising problems and making requests. Extensionists seen in the TOT and normal bureaucratic mode are there to pass on messages and packages downwards, not to multiply work for their senior officers by passing varied requests upwards. Second, most NARSs lack capacity to respond to needs and requests articulated by farmers for material or information. In practice, most management information systems are designed to feed information upwards to serve central management, rather than to draw it downwards to serve farmers. Six of the seven management information systems listed in 1987 for agricultural research in the Philippines were for central management; only one, the Research Information Storage and Retrieval System, was to provide information useful at the grassroots, and that was described in the future tense, with the statement that financial support was needed to extend it into the regions. Many NARSs have poor institutional memories for research findings (see e.g. Kean and Singogo Lingston, 1988, p48), and work often has to be repeated because earlier records cannot be found. Few, if any, are yet set up well enough to provide diverse information, genetic material and technologies to meet diverse local demand.

The practical implications are for agricultural research and extension organizations to make three changes: to encourage field staff to search for, support and spread farmers' innovations; to judge and reward staff by the requests they make upwards in response to analysis and demands by farmers; and to develop information and supply systems to respond to those demands.

(iii) Incentives. As with any new paradigm, professionals who innovate in the farmer-first mode risk being marginalized. In the short term, the safest route to promotion will often seem to be work on-station not on-farm; on irrigated agriculture, not rainfed (and least of all on unreliable rainfed); on a single commodity, not complex combinations; on industrial, commercial and major cereal crops not low status subsistence food crops; with quick maturing annuals not slow maturing perennials like shrubs and trees; and with validation through standard experimental design not farmers' adoption. Nor does improving complex, diverse and risk-prone (CDR) farming lend itself to the statistical testing methods taught in textbooks, involving as it often does complex and multiple simultaneous change, for example, agroforestry combined with water harvesting, growing fish with rainfed rice, home gardening with several canopies, or the creation and exploitation of protected micro-environments in semi-arid conditions. More papers can be produced more reliably by using conventional methods on conventional crops in conventional environments, where there is already a good information base, than by using unconventional methods on unconventional agricultural practices in unconventional environments. Where promotions boards judge candidates only by adherence to standard methods, or numbers of publications, rather than farmers' adoption, then pioneers in farmer-first modes will not do as well as their less innovative colleagues.

The rapid transfer of agricultural research staff poses a further problem especially in sub-Saharan Africa. The costs in lost continuity and effectiveness in formal on-station research are well known. Less well recognized is the way in which rapid turnover reduces incentives for staff to build up relations with farmers, and undermines farmers' confidence in them.

The practical implications of these obstacles are to develop enabling conditions and incentives. The several forms these can take include the following:

- assessing research staff less on publications, and extension staff less on the achievement of targets; and both more on the demands and searches they initiate on behalf of farmers, on farmers' interest and innovation and on adoption and spread of technology;
- rewarding those who pioneer and write about new methods. Until recently, farmer-first research methods were not much the subject of articles in the harder scientific journals, but as the summer 1988 issue of *Experimental Agriculture* (Farrington, 1988) has shown, this is changing. As scientists come to realize that they can publish articles about their methods and experiences, and that these bring national and international recognition, publishing disincentives should not just disappear but be reversed;
- ensuring more continuity for scientists in field posts. This may be difficult for many reasons. Fortunately, where lack of staff continuity is endemic, experimenting farmers and local organizations may be able, more and more, to provide their own continuity;
- networking between farmer-first researchers, providing mutual support and recognition.

The strongest incentive, though, is professional and personal satisfaction. Those who make reversals and changes in directions like those in this book, and who work collegially with farmers, soon find it intellectually and professionally exciting, enjoyable, and even fun, with the supreme reward of effectively helping farmers to do better. This is the most hopeful aspect. For even if other conditions are adverse, more and more will want to work in the farmer-first mode for the simple and sound reason that it satisfies and succeeds.

Methods and Interactions

In themselves, these three things – decentralization and resources, organization for search and supply, and providing incentives – are not enough. Much also depends on what is done and how it is done – on the methods available and the quality of interactions.

The need here is to develop further, describe and disseminate farmer-first methods in detail. Just as the aim is to widen choice of practices for resource-poor farmers, so it is to widen choice of methods for scientists and extensionists. Some of these are methods for decentralization, for search and supply and for farmers' experiments; yet others are for interactions between professionals and farmers. Many such methods are now known. Those that are most promising deserve to be evaluated, written up and made accessible through manuals and practical training.

The more important methods to be developed and described include:

- aiding farmers' analysis and learning their agendas;
- getting started with families and communities;
- finding out about agricultural research (for NGOs);
- finding and supporting farmers' experiments;
- convening and assisting groups;
- convening and managing innovator workshops;
- searching, and supplying farmers with what they want and need;
- designing and managing incentives for scientists;
- communicating: farm family and outsider face to face.

This last, concerning the quality of interaction between farmers and scientists, is as crucial as it has been neglected. Most accounts and manuals concentrate on the mechanics of methods, as though rules guarantee results. This is not so. As social anthropologists, sociologists and some psychologists know, and as is only common sense, the quality of the face-to-face relationship can make or mar an interview or discussion; and much depends on mutual respect and rapport.

Good advice is available (see e.g. Rhoades, 1982; Grandstaff and Grandstaff, 1987) but one may still ask how many scientists and extensionists have a grounding in the significance of non-verbal cues, of seating arrangements, of demeanour and manners and of that respect for and interest in people and what they have to show and say which makes for free and open communication.

Even good manuals and training for farmer-first methods and manners cannot by themselves guarantee good results. After institutions, incentives and interactions, there remains personality. Personal styles and aptitudes differ. The contrast between the closed blueprint approach to development and the open learning process (Korten, 1980, 1984) parallels the contrast between TOT and farmer first. Some people are more at home with blueprints, with fixed plans and rules, and with clear ideas of what is expected and what will be officially rewarded. For them, the TOT mode fits better. Others are more at ease with learning processes, with open-ended exploration, with deciding for themselves how to proceed as they go along, and with the reward of knowing in themselves that they have done well. They will be better with the farmer-first mode.

A Pluralist Strategy

For farmer-first reversals, pluralism is one key to effective action. Individuals have different inclinations, aptitudes and opportunities, and these change over time. Organizations have different potentials, and these vary between countries, regions and environments, and also change. There is no standard situation and no one formula, but there are questions of where to start.

Besides NARSs, the obvious natural leaders at first sight are the International Agricultural Research Centres. They are seen as prestigious sources of innovation, and they set standards for agricultural research. They train many of the more able national scientists. Their publications are easily available and widely consulted. They do, though, have disadvantages. At least one centre (ICRISAT) has a mandate which is said to impede on-farm and with-farmer technology generation. The number of non-economist social scientists is everywhere low, and sometimes derisory. Many of the centres' staff do not speak local vernaculars and so cannot listen directly to farmers. Excellent facilities, normal professional aspirations and high status frontiers such as biotechnology, combine to hold scientists at the central research stations and out of contact with farmers. To their credit, CIP (the International Potato Centre) in Peru and CIAT in Colombia have pioneered and popularized farmer-first methods and some staff at the International Rice Research Institute (IRRI) in the Philippines are active. But the numbers of staff involved are still small, and it remains to be seen how far and fast they and others can go. For the present, the powerful influences of the international centres mostly reinforce the conventional TOT paradigm. The centres are still more of the problem than of the solution. But they need not remain so. With a new vision and understanding, they could lead in developing, improving and spreading the farmer-first approach and methods.

Agricultural universities and faculties, and management institutes which train scientists and extensionists, are another focus for change. Some universities are bastions of conservatism, doggedly reproducing narrow professionalism in their students. Others are more open and innovative. By changing their curricula and teaching, by rewriting their textbooks and by introducing learning from and with farmers, universities and training institutes could help mould and transform the values and behaviour of new generations of scientists and extensionists.

Given their influence, size and coverage, these large organizations – International Agricultural Research Centres, NARSs, national agricultural extension organizations and universities and faculties – must in the longer term be transformed if the gross imbalance between TOT and farmer-first is to be corrected. To achieve this on their own, in isolation, would be difficult though. Fortunately, three other, smaller-scale, types of organization and arrangement provide more favourable environments for reversals and change. These are projects, NGOs and farmers' organizations.

Special projects, working in various combinations with NARSs, are well represented by the contributions to this book: the Agricultural Research Planning Teams in Zambia (Kean and Singogo Lingston, 1988), the Agricultural Technology Improvement Project in Botswana (Norman et al, 1988), the Tropsoils Project in West Sumatra (Colfer et al, 1985), the Agricultural Research and Production Project in Nepal (Mathema and Galt, 1987) and the Farming Systems Development Project in the Eastern Visayas in the Philippines (Lightfoot et al, 1987; Repulda et al, 1987). These projects combined special resources with staff who wished to work closely with farmers, and who had the freedom to do so.

For their part, international and national NGOs have advantages. It is true that they are scattered, of variable quality and usually small. They have also, as a whole, tended to be weak on the technical side of agriculture and inexpert at making links with formal agricultural research. Change, though, is rapid. In the late 1980s, many have been shifting their priorities, staff recruitment and training towards agriculture. NGOs have a comparative advantage, especially when they can maintain the same good staff in the field in the same place for a number of years. Some, like World Neighbors, the Central Mennonites Committee, the Aga Khan Rural Support Programmes, Oxfam, and Save the Childen Fund, already have a track record in farmer-first innovation. NGOs like these find it easier than large bureaucracies to avoid the trap of TOT, to recruit and maintain sensitive staff in the field, to be close to farmers, to encourage their participation and to act in farmer-first roles.

Farmers' organizations are a form of national NGO of growing significance. They have an increasing capacity to make demands on NARSs and to influence and sometimes even fund research. They tend, though, to represent the better-endowed farmers and those who produce for standard large-scale markets. The resource-poor farmers of CDR agriculture tend to be unorganized and to have diverse needs which defy simple aggregation. For them, demand-pull will always be weaker and the responsibility for putting their priorities first rests much more with other NGOs and with individual professionals.

A plurality of organizations can combine to gain strength in diversity. This has been observed in Eastern Bolivia (Thiele et al, 1988), where area-based development projects, NGOs and producers' organizations have been 'intermediate users' of technology, exercising demands on the formal research organization on behalf of farmers. There and elsewhere, both organizational links and staff careers are becoming more varied and plural. Projects provide resources for scientists to travel and for fieldwork with farmers. NGOs arrange visits for farmers to other areas. NGOs overcome their lack of agricultural competence by recruiting staff who leave government service, or, as in the Sudan, by paying them supplements while they remain on the government payroll.

A pluralist strategy, involving a variety of large and small organizations, partly answers questions of cost-effectiveness in the use of scientists' time. Sometimes the opportunity costs of scientists working on CDR agriculture may appear high, for instance if an African country has only a few scientists to work on an industrial crop of national importance. Further, there are usually far fewer scientists per farming system in CDR than in Green Revolution agriculture. A case could be put that scientists' impact working on CDR agriculture will be low. This has been evident so far. Concern is expressed that so much of the output of research is not adopted by farmers, with the rate of rejection in India informally estimated at 80 per cent or more, with probably a higher figure for rainfed agriculture.

The farmer-first mode promises greater cost-effectiveness. Where NGOs or extension agents are the convenors, catalysts and communicators, scientists can be used sparingly as consultants. When farmers play a full part, they themselves take account of local diversity in a manner that makes low demands on scarce scientific staff. When scientists spend more time searching for genetic material, technologies and principles for farmers to try, adapt and choose between, they may have more impact. Above all, putting farmers' agendas first and helping them to meet their priorities should be a sure path to good use of time. In a plural farmer-first approach, farmers, NGO workers, extensionists and agricultural researchers can specialize and support each other, with farmers and their groups and networks doing most, and the others serving them. In making the most of scarce staff, pluralism should pay off.

Practical Action: Starting and Sustaining Change

Professionals concerned with agricultural innovation, research and extension – whether they are farmers, or physical, biological or social scientists, and whether they are independent or working in universities, training institutes, government departments or NGOs – will have found in this book many ideas for what they might do. Non-farming agricultural professionals, just like resource-poor farmers, are faced with diversity and complexity, and similarly need a repertoire of methods so that they can be versatile and adaptable.

At a personal level, it is tempting to say that nothing can be done until a whole bureaucratic and professional system changes. Usually, though, there is room for manoeuvre. Some steps can be taken; a start can almost always be made. Even if the start is small and progress slow, it may be the seed of a self-sustaining movement. In the spirit of the learning process approach to development, it is better to start, to do something and to learn on the way, than to wait for better conditions before acting.

In the spirit of pluralism, action can and should start in many places. But not everything can be done at once. There are questions of how and where to start.

Two principles help here. The first is to start where it is easier, simpler and quicker, while weighing the danger of biases against poorer farmers. It is better to start and learn by doing and through mistakes than to wait for perfect conditions. By starting, experience is gained and confidence built up.

The second principle is to change behaviour before attitudes. Preaching about attitudes invites acquiescence without deep change. Action means experience gained and that, more than exhortation, reorients attitudes and habits of thought.

Taking these two principles together, analysis by and with farmers appears the most promising point of entry, followed by search, choice and experiment. A basic question to ask is what farmers would like in their basket of choices. From this question follow demands which reverse the normal top-down flow. Whether a department of agriculture, a university, an NGO or combinations of these can handle such requests can then be put to the test. Activities and roles then have to change. Procedures to accept and handle demands are required. Information systems for management from below have to be created and made to work. Subsequently, other elements of the paradigm become active, with testing and experiments by farmers and consultative support by others.

It is one thing to start and establish a bridgehead. It is quite another to sustain and spread it. The experiences reported by the International Service for National Agricultural Research's (ISNAR) On-Farm Client-Oriented Research project in nine national institutes are sobering. They include difficulty maintaining an interdisciplinary focus, vulnerability to the withdrawal of special support, a tendency to methodological stagnation, a loss of early enthusiasm and of farmer participation, and a career ladder which leads away from collaboration on-farm and towards specialization on-station (Merrill-Sands, 1988; von der Osten et al, 1988). With farmer-first, similar problems can be expected but also differences. The approach and methods described by the contributors to this book go further than most on-farm research, exploiting as they do the comparative advantage of farmers' knowledge, continuity and capacity for innovation. When it is farmers, with their full experience of their own farming systems, who analyse, experiment, monitor and make judgments, it is less important to sustain an interdisciplinary focus; farmers' enthusiasm and participation are more likely; and if outside support weakens, farmers can carry on on their own, and make their own demands on the research system, strengthened by their personal interest and participation. Compared with on-farm research in the TOT mode, the farmer-first mode promises to be feasible with a lighter touch and sustainable with less outside support.

Finally, for professionals to innovate by working in the farmer-first mode demands vision and leadership on the part of those with power and responsibility. These include senior officials in capital cities, vice-chancellors and deans, directors of research stations, leaders of teams and senior staff in regional, provincial and district headquarters, as well as in aid agencies and NGOs. Leaders can act like normal professionals and normal bureaucrats who simplify, standardize and stifle; or they can break out and encourage and support initiative and change, providing resources and room for manoeuvre for those under their management who have the aptitude and will to work in new participatory ways; and they can reorganize departments, procedures and management information systems so that searches can be made to meet farmers' demands and fill their basket with choices.

Alliances and mutual support also help. Those who see or sense the potential will do well to seek out and support like-minded fellow professionals in their own and other organizations. Shared ideas and experiences speed up learning. If those in this book provide stimulus and encouragement, they will have served their purpose. And if the new paradigm fulfils its promise, and is accepted and practiced much more in the 1990s and the 21st century, then those who take risks now to support, develop and spread it will not have acted in vain.

For the stakes are high. Over a billion people are supported by the third agriculture. The challenge is to enable many of the poorer among them to secure better and more sustainable livelihoods from their complex, diverse and risk-prone farming when normal agricultural research has so largely failed. This book points to new potentials. It shows that reversals in the farmer-first mode can be effective for farmers and exciting for professionals. A quiet revolution has already started, but it is scattered and still small scale. Which countries, institutions and individuals will now lead remains to be seen. Change depends on personal decisions and action. Those who now explore the frontiers of farmer participation cannot expect Nobel prizes, or be confident of early recognition or promotion; but they will be joining a vanguard. Their rewards, more surely, will be the exhilaration of pioneering, the satisfaction of seeing innovations spread and the knowledge that through their work, poor farm families are being truly served.

Participatory Learning for Sustainable Agriculture

Jules Pretty

Recent Impacts of Sustainable Agriculture

During the past 50 years, agricultural development policies and practices have successfully emphasized external inputs as the means to increase food production. This has led to growth in global consumption of pesticides, inorganic fertilizer, animal feedstuffs, and tractors and other machinery.

These external inputs have, however, tended to substitute for natural processes and resources, rendering them more vulnerable. Pesticides have replaced biological, cultural and mechanical methods for controlling pests, weeds and diseases; inorganic fertilizers have substituted for livestock manures, composts and nitrogen-fixing crops; information for management decisions comes from input suppliers, researchers and extensionists rather than from local sources; machines have replaced labour; and fossil fuels have substituted for local energy sources. The basic technical challenge for those concerned with sustainable agriculture is to make better use of these internal resources. This can be done by minimizing the external inputs used, by regenerating internal resources more effectively, or by combinations of both.

There is now emerging evidence that regenerative and resource-conserving technologies and practices can bring both environmental and economic benefits for farmers, communities and nations. The best evidence comes from countries of Africa, Asia and Latin America, where the concern is to increase food production in the areas where farming has been largely untouched by the modern packages of externally supplied technologies. In these complex and remote lands, some farming communities adopting regenerative technologies have substantially improved agricultural yields, often only using few or no external inputs (Bunch, 1991, 1993; GTZ, 1992; UNDP, 1992; Lobo and Kochendörfer-Lucius, 1992; Krishna, 1993; Shah, 1994; SWCB, 1994; Balbarino and Alcober, 1994; Pretty, 1995).

This article was published in *World Development* 23(8) 3, Pretty, J. N., Participatory learning for sustainable agriculture, 1245–1263, copyright Elsevier (1995).

But these are not the only sites for successful sustainable agriculture. In the high-input and generally irrigated lands, farmers adopting regenerative technologies have maintained yields whilst substantially reducing their use of inputs (Bagadion and Korten, 1991; Kenmore, 1991; van der Werf and de Jager, 1992; UNDP, 1992; Kamp et al, 1993; Pretty, 1995). And in the very high input lands of the industrialized countries, farmers have been able to maintain profitability, even though input use has been cut dramatically, such as in the USA (Liebhart et al, 1989; NRC, 1989; Hanson et al, 1990; Faeth, 1993; NAF, 1994); and in Europe (El Titi and Landes, 1990; Vereijken, 1990; Jordan et al, 1993; Pretty and Howes, 1993; Reus et al, 1994).

All of these successes have elements in common. Farmers have made use of resource-conserving technologies, such as Integrated Pest Management, soil and water conservation, integrated plant nutrition and recycling, multiple cropping, water harvesting and waste recycling. There has been action by groups and communities at local level, with farmers becoming experts at managing farms as ecosystems, and at collectively managing the watersheds or other resource units of which their farms form part. And there have been supportive and enabling external government and/or non-government institutions, often working in new partnerships with new participatory methodologies, which have reoriented their activities to focus on local needs and capabilities.

Sustainability as a Contested Term

Although it is relatively easy to describe goals for a more sustainable agriculture, things become much more problematic when it comes to attempts to define sustainability: 'everyone assumes that agriculture must be sustainable. But we differ in the interpretations of conditions and assumptions under which this can be made to occur' (Francis and Hildebrand, 1989, p8).

A great deal of effort has gone into trying to define sustainability in absolute terms. Since the Brundtland Commission's definition of sustainable development (WCED, 1987), there have been at least 70 more definitions constructed, each different in subtle ways, each emphasizing different values, priorities and goals. The implicit assumption in many is that it is possible to come up with a single correct definition. Each author presumably regards his or her effort as the best.

But precise and absolute definitions of sustainability, and therefore of sustainable agriculture, are impossible. Sustainability itself is a complex and contested concept. To some it implies persistence and the capacity of something to continue for a long time. To others, it implies resilience, and the ability to bounce back after unexpected difficulties. With regard to the environment, it is used to imply not damaging or degrading natural resources. Others see it as a concept that means developmental activities that simply take account of the environment. Economies are sometimes said to be sustainable if economic activities do not harm the natural resource base; to others, sustainability simply implies continuing to grow at the same rate.

In any discussions of sustainability, it is important to clarify what is being sustained, for how long, for whose benefit and at whose cost, over what area and measured by what criteria. Answering these questions is difficult, as it means assessing and trading off values and beliefs (Campbell, 1994a). It also means that we can never be certain about sustainability. The 'undecidability theorem', proved by the logician Alan Turing in the 1930s, captures this essence: the theorem says that no matter how clever we think we are, there will always be algorithms (sets of rules) that do things we cannot predict in advance. The only way to find out what will happen is to run them (in Waldrop, 1992, p234).

Nonetheless, when specific parameters or criteria are selected, it is possible to say whether certain trends are steady, going up or going down. At the farm or community level, it is possible for actors to weigh up, trade off and agree on these criteria for measuring trends in sustainability. But as we move to higher levels of the hierarchy, to districts, regions and countries, it becomes increasingly difficult to do this in any meaningful way.

It is critical, therefore, that sustainable agriculture does not prescribe a concretely defined set of technologies, practices or policies. This would only serve to restrict the future options of farmers. Although many resource-conserving technologies and practices have been widely proven on research stations to be both productive and environmentally sensitive, the total number of farmers using them is still small. Part of the problem is that scientists experience quite different conditions to those experienced by farmers, and few farmers are able to adopt the whole packages of technologies without considerable adjustments. Despite the benefits of resource-conserving technologies, if they are imposed on farmers, then they will not be adopted widely.

One example is alley cropping, an agroforestry system comprising rows of nitrogen-fixing trees or bushes separated by rows of cereals, which has long been the focus of research (Kang et al, 1984; Attah-Krah and Francis, 1987; Lal, 1989). Many productive and sustainable systems, needing few or no external inputs, have been developed. They stop erosion, produce food and wood and can be cropped over long periods. But the problem is that very few, if any, farmers have adopted these alley cropping systems as designed. Despite millions of dollars of research expenditure over many years, systems have been produced suitable only for research stations. Where there has been some success, however, is where farmers have been able to take one or two components of alley cropping, and then adapt them to their own farms. In Kenya, for example, farmers planted rows of leguminous trees next to field boundaries, or single rows through their fields; and in Rwanda, alleys planted by extension workers soon became dispersed through fields (Kerkhof, 1990).

But the prevailing view tends to be that it is farmers who should adapt to the technology. Of the Agroforestry Outreach Project in Haiti, it was said that 'Farmer management of hedgerows does not conform to the extension program... Some farmers prune the hedgerows too early, others too late. Some hedges are not yet pruned by two years of age, when they have already reached heights of 4–5 metres. Other hedges are pruned too early, mainly because animals are let in or the tops are cut and carried to animals... Finally, it is very common for farmers to allow some of the trees in the hedgerow to grow to pole size' (Bannister and Nair, 1991, pp54–55).

This contrasts starkly with a recent analysis of sustainable agriculture initiatives in Guatemala and Honduras. A learning group from the non-governmental organization (NGO), COSECHA, returned to areas where projects had ended 3, 4 and 15 years previously, and used participatory methods with local communities to investigate changes (Bunch and López, 1994). They found that those communities in the project areas were substantially better off economically and socially. But, surprisingly, many of the technologies known to be 'successful' during the project (those that had increased crop yields without damaging the environment) had been completely replaced by new practices and, in all, some 80–90 innovations were documented. This has led Bunch and López (personal communication, 1994) to conclude that 'technologies are not sustainable: what needs to be made sustainable is the process of innovation itself'.

As conditions and knowledges change, so must farmers and communities be encouraged and allowed to change and adapt too. Again, this implies that any definitions of sustainability are time- and place-specific. As situations and conditions change, so must our constructions of sustainability also change. Sustainable agriculture is, therefore, not simply an imposed model or package. It must become a process for learning and perpetual novelty.

Science and Sustainability

Although there exist successful applications of sustainable agriculture throughout the world, still relatively few farmers have adopted new technologies and practices. One reason is that sustainable agriculture presents a deeper and more fundamental challenge than many researchers, extensionists and policy makers have yet supposed. Sustainable agriculture needs more than new technologies and practices. It needs agricultural professionals willing and able to learn from farmers and other stakeholders; it needs supportive external institutions; it needs local groups and institutions capable of managing resources effectively; and above all it needs agricultural policies that support these features. It also requires we look closely at the very nature of the way we conceptualize sustainability and how it might be achieved (Pretty, 1994, 1995).

Since the early 17th century, scientific investigation has come to be dominated by the Cartesian paradigm, commonly called positivism or rationalism. This posits that there exists an objective external reality driven by immutable laws. Science seeks to discover the true nature of this reality, the ultimate aim being to discover, predict and control natural phenomena. Investigators proceed in the belief that they are detached from the world. The process of reductionism involves breaking down components of a complex world into discrete parts, analysing them, and then making predictions about the world based on interpretations of these parts. Knowledge about the world is then summarized in the form of universal, or time- and context-free, generalizations or laws.

This methodology of science has been hugely successful, producing technologies and medicines that have enabled many people to live safer and more comfortable lives than ever before (Funtowicz and Ravetz, 1993). It is an approach that clearly works, and as a consequence, investigation with a high degree of control over the system being studied and where system uncertainties are low has become equated with good science. And such science is readily equated with 'true' knowledge, and so the 'only proper way' of thinking and doing.

But it is also this positivist approach that has led to the generation of farming technologies that have been applied widely and irrespective of local context. Where it has been possible to influence and control farmers, either directly or through economic incentives or markets, agricultural systems have been transformed. But where neither the technologies have fitted local systems nor have farmers been controlled, then agricultural modernization centred on positivist science has passed rural people by.

What the positivist paradigm does not recognize is that all data are constructed within a particular social and professional context. This context affects the outcomes, and can have a profound impact on policy and practice in agricultural development.

Michael Stocking (1993) has described just how the values of the investigators affect the end result when it comes to soil erosion data. Since the 1930s, there have been at least 22 erosion studies conducted in the Upper Mahaweli Catchment in Sri Lanka. These have used visual assessments of soil pedestals and root exposure, erosion pins, sediment traps, run-off plots, river and reservoir sediment sampling, and predictive models. Between the highest and lowest estimates of erosion under mid-country tea, there is an extraordinary variation of some 8000-fold, from 0.13 t/ha/yr to 1026 t/ha/yr (El-Swaify et al, 1983; NEDCO, 1984; Krishnarajah, 1985). The highest estimate was in the context of a development agency seeking to show just how serious erosion is in the developing world; the lowest was by a tea research institute seeking to show how safe was their land management. There was, however, nothing wrong with the scientific method; it was more a question of what the researchers defined as a problem, and how they chose to investigate it.

A similar case is described by Jerome Delli Priscoli (1989) regarding water and energy in the north-west of the USA. One projection for energy needs showed a steady growth to the year 2000; this was conducted by the utility company. Another showed a steadily downward trend; this was conducted by environmental groups. Other projections by consultancy groups were found towards the centre. What does this say about the data? 'Each projection was done in a statistically "pedigreed" fashion. Each was logical and internally elegant, if not flawless. The point is, once you know the group, you will know the relative position of their projection. The group, organization or institution embodies a set of values. The values are visions of the way the world ought to be' (Delli Priscoli, 1989, p36).

Both cases illustrate that science is not the neat, objective collection of facts about nature and its processes. The data were clearly constructed by people with values and human foibles. As Stocking (1993, p12) put it: 'What, then, is the right policy response? … Not surprisingly policy makers pick the measurements to suit their needs.' The challenge is not just that these differences have to be recognized, but that the competing values need to be mediated so as to produce agreements between actors with very different agendas. This calls for better forms of active participation and new platforms for decision making that engage wider public interests and social movements (Woodhill, 1993; Röling, 1994).

Alternatives and Additions to the Positivist Paradigm

One problem with the positivist paradigm is that its absolutist position appears to exclude other methodologies. Yet the important point about positivism is that it is just one of many ways of describing and analysing the world, and what is needed are pluralistic ways of thinking about the world and acting to change it (Kuhn, 1970; Feyerabend, 1975; Vickers, 1981; Checkland, 1981; Reason and Heron, 1986; Habermas, 1987; Giddens, 1987; Maturana and Varela, 1987; Rorty, 1989; Bawden, 1991; Uphoff, 1992; Wynne, 1992; Chambers, 1993; Funtowicz and Ravetz, 1993; Röling, 1994). Recent years have seen the emergence of a remarkable number of advances in a wide range of disciplines and fields of investigation. The sources include the so-called 'harder' sciences, such as physics, biology, chemistry, meteorology and mathematics, as well as the 'softer' sciences of philosophy, economics, sociology, architecture and organizational management.[1]

Despite this wide ranging list, those arguing for the seriousness and importance of developing additions to positivism are still in the minority. Many scientists continue to argue strongly that information is first produced by science, and only then interpreted and applied by the public and policy makers. It is this process of interpretation that is said to introduce values and confuse certainties. Yet the results from any investigation are always going to be open to different interpretations. All actors and stakeholders, and particularly those with a direct social or economic involvement and interest, have different perspectives on what constitutes a problem and/or improvement in an agricultural system.

These advances in alternative paradigms have important implications for how we go about finding out about the world, generating information and so taking action. All hold that 'the 'truth' is ultimately a kind of mirage that in principle cannot be achieved because the worlds we know are those crafted by us' (Eisner, 1990, p89). All suggest that we need to reform the way we think about methodologies for finding out about the world. Although these alternatives are emerging from a wide range of disciplines, there are five principles that differentiate them from positivist science (Pretty, 1994).

The first is that any attempt precisely to define concepts like sustainability is fundamentally flawed. It is a contested concept, and so represents neither a fixed set of practices or technologies, nor a model to describe or impose on the world. The question of defining what we are trying to achieve is part of the problem, as each individual has different values. Sustainable agriculture is, therefore, not so much a specific farming strategy as it is an approach to learning about the world.

The second is that problems are always open to interpretation. All actors have uniquely different perspectives on what is a problem and what constitutes improvement. As knowledge and understanding are socially constructed, what each of us knows and believes is a function of our own unique contexts and pasts. There is, therefore, no single 'correct' understanding. What we take to be true depends on the framework of knowledge and assumptions we bring with us. Thus it is essential to seek multiple perspectives on a problem situation by ensuring the wide involvement of different actors and groups.

The third is that the resolution of one problem inevitably leads to another 'problem-situation', as problems are endemic. The reflex of positivist science is to seek to collect sufficient data before declaring certainty about an issue or problem. As this position is believed to reflect the 'real world', then courses of action can become fixed and actors no longer seek information that might give another interpretation. Yet in a complex and changing world, there will always be uncertainties and new interpretations.

The fourth is that the key feature now becomes the capacity of actors (professionals, farmers and the public) continually to learn about these changing conditions, so that they can act quickly to transform existing activities. All should make uncertainties explicit and encourage rather than obstruct wider public debates about pursuing new paths for agricultural development. The world is open to multiple interpretations, and so it is impossible to say which one is true. Different constructed realities can only be related one to another.

The fifth is that systems of learning and action are needed to seek the multiple perspectives of the various interested parties and encourage their greater involvement. The view that there is only one epistemology (that is, the scientific one) has to be rejected. Participation is an essential component of any system of learning, as any change cannot be effected without the full involvement of all stakeholders and the adequate representation of their views and perspectives. As Sriskandarajah et al (1991, p4) put it: 'ways of researching need to be developed that combine "finding out" about complex and dynamic situations with "taking action" to improve them, in such a way that the actors and beneficiaries of the "action research" are intimately involved as participants in the whole process'.

All of this indicates that it is clearly time to break the domination of the old paradigm of positivism for science, and so explore the alternatives. This is not to suggest that there is no place for reductionist and controlled science. This will continue to have an important role to play where system uncertainties are low and problems are well defined and agreed. But it will no longer be seen as the sole type of inquiry. The process will inevitably mean huge transformations. Thomas Kuhn's

(1970) hugely influential analysis of paradigm changes in science describes the process of revolution for case after case. But the process can bring big shifts in understanding: 'During revolutions scientists see new and different things when looking with familiar instruments in places they have looked before' (Kuhn, 1970, p111).

The fundamental challenge facing agricultural scientists and development professionals is to find effective ways of involving a wider peer community (Funtowicz and Ravetz, 1993) and a greater breadth of social and cultural institutions (Woodhill, 1993) in the business of developing a more sustainable agriculture. Fortunately, they do not need to start just with theoretical analyses to shift underlying values. From practice, there has emerged a rich experience of the use of participatory methods for just this purpose.

The Many Interpretations of Participation

There is a long history of participation in agricultural development, and a wide range of development agencies, both national and international, have attempted to involve people in some aspect of planning and implementation. Two overlapping schools of thought and practice have evolved. One views participation as a means to increase efficiency, the central notion being that if people are involved, then they are more likely to agree with and support the new development or service. The other sees participation as a fundamental right, in which the main aim is to initiate mobilization for collective action, empowerment and institution building.

In recent years, there have been an increasing number of comparative studies of development projects showing that 'participation' is one of the critical components of success. It has been associated with increased mobilization of stakeholder ownership of policies and projects; greater efficiency, understanding and social cohesion; more cost-effective services; greater transparency and accountability; increased empowering of the poor and disadvantaged; and strengthened capacity of people to learn and act (Montgomery, 1983; Paul, 1987; USAID, 1987; Baker et al, 1988; Reij, 1988; Finsterbusch and van Wicklen, 1989; Bagadion and Korten, 1991; Cernea, 1991; Guijt, 1991; Kottak, 1991; Pretty and Sandbrook, 1991; Uphoff, 1992; Narayan, 1993; World Bank, 1994).

As a result, the terms 'people's participation' and 'popular participation' are now part of the normal language of many development agencies, including NGOs, government departments and banks (Adnan et al, 1992; Bhatnagar and Williams, 1992; World Bank, 1994). It is such a fashion that almost everyone says that participation is part of their work. This has created many paradoxes. The term 'participation' has been used to justify the extension of control of the state as well as to build local capacity and self-reliance; it has been used to justify external decisions as well as to devolve power and decision making away from external agencies; it has been used for data collection as well as for interactive analysis. But 'more often than not, people are asked or dragged into partaking in operations of no interest to them, in the very name of participation' (Rahnema, 1992, p116).

One of the objectives of agricultural support institutions must, therefore, be greater involvement with and empowerment of diverse groups of people, as sustainable agriculture is threatened without it. The dilemma for many authorities is they both need and fear people's participation. They need people's agreements and support, but they fear that this wider involvement is less controllable, less precise and so likely to slow down planning processes. But if this fear permits only stage-managed forms of participation, then distrust and greater alienation are the most likely outcomes. This makes it all the more crucial that judgements can be made on the type of participation in use.

In conventional rural development, participation has commonly centred on encouraging local people to sell their labour in return for food, cash or materials. Yet these material incentives distort perceptions, create dependencies, and give the misleading impression that local people are supportive of externally driven initiatives. This paternalism undermines sustainability goals and produces impacts which rarely persist once the project ceases (Bunch, 1983; Reij, 1988; Pretty and Shah, 1994; Kerr, 1994). Despite this, development programmes continue to justify subsidies and incentives, on the grounds that they are faster, that they can win over more people, or they provide a mechanism for disbursing food to poor people. As little effort is made to build local skills, interests and capacity, local people have no stake in maintaining structures or practices once the flow of incentives stops.

The many ways that development organizations interpret and use the term participation can be resolved into seven clear types. These range from manipulative and passive participation, where people are told what is to happen and act out predetermined roles, to self-mobilization, where people take initiatives largely independent of external institutions (Table 7.1). This typology suggests that the term 'participation' should not be accepted without appropriate clarification. The World Bank's internal 'Learning Group on Participatory Development', in seeking to clarify the benefits and costs of participation, distinguished between different types of participation: 'many Bank activities which are termed "participatory" do not conform to [our] definition, because they provide stakeholders with little or no influence, such as when [they] are involved simply as passive recipients, informants or labourers in a development effort' (World Bank, 1994, p6). The problem with participation as used in types one to four is that any achievements are likely to have no positive lasting effect on people's lives (Rahnema, 1992). The term participation can be used, knowing it will not lead to action. Indeed, some suggest that the manipulation that is often central to types one to four mean they should be seen as types of non-participation (Hart, 1992).

A recent study of 230 rural development institutions employing some 30,000 staff in 41 countries of Africa found that participation for local people was most likely to mean simply having discussions or providing information to external

Table 7.1 *A typology of participation: How people participate in development programmes and projects*

Typology	*Characteristics of each type*
1 *Manipulative participation*	Participation is simply a pretence, with 'people's' representatives on official boards but who are unelected and have no power
2 *Passive participation*	People participate by being told what has been decided or has already happened. It involves unilateral announcements by an administration or project management without any listening to people's responses. The information being shared belongs only to external professionals
3 *Participation by consultation*	People participate by being consulted or by answering questions. External agents define problems and information gathering processes, and so control analysis. Such a consultative process does not concede any share in decision making, and professionals are under no obligation to take on board people's views
4 *Participation for material incentives*	People participate by contributing resources, for example labour, in return for food, cash or other material incentives. Farmers may provide the fields and labour, but are involved in neither experimentation nor the process of learning. It is very common to see this called participation, yet people have no stake in prolonging technologies or practices when the incentives end
5 *Functional participation*	Participation seen by external agencies as a means to achieve project goals, especially reduced costs. People may participate by forming groups to meet predetermined objectives related to the project. Such involvement may be interactive and involve shared decision making, but tends to arise only after major decisions have already been made by external agents. At worst, local people may still only be co-opted to serve external goals
6 *Interactive participation*	People participate in joint analysis, development of action plans and formation or strengthening of local institutions. Participation is seen as a right, not just the means to achieve project goals. The process involves interdisciplinary methodologies that seek multiple perspectives and make use of systemic and structured learning processes. As groups take control over local decisions and determine how available resources are used, so they have a stake in maintaining structures or practices
7 *Self-mobilization*	People participate by taking initiatives independently of external institutions to change systems. They develop contacts with external institutions for resources and technical advice they need, but retain control over how resources are used. Self-mobilization can spread if governments and NGOs provide an enabling framework of support. Such self-initiated mobilization may or may not challenge existing distributions of wealth and power

Source: Adapted from Pretty (1994), Satterthwaite et al (1995), Adnan et al (1992), Hart (1992) agencies (Guijt, 1991). Government and non-government agencies rarely permitted local groups to work alone, some even acting without any local involvement. These external agencies did permit some joint decisions, but usually controlled all the funding.

Another study of 121 rural water supply projects in 49 countries of Africa, Asia and Latin America found that participation was the most significant factor contributing to project effectiveness and maintenance of water systems (Narayan, 1993). Most of the projects referred to community participation or made it a specific project component, but only 21 per cent scored high on interactive participation. Clearly, intentions did not translate into practice. It was when people were involved in decision making during all stages of the project, from design to maintenance, that the best results occurred. If they were just involved in information sharing and consultations, then results were much poorer. According to the analysis, it was quite clear that moving down the typology moved a project from a medium to highly effective category.

Great care must, therefore, be taken over both using and interpreting the term participation. It should always be qualified by reference to the type of participation, as most types will threaten rather than support the goals of sustainable agriculture. What will be important is for institutions and individuals to define better ways of shifting from the more common passive, consultative and incentive-driven participation towards the interactive end of the spectrum.

Alternative Systems of Learning and Action

Recent years have seen a rapid expansion in new participatory methods and approaches to learning in the context of agricultural development (see *PLA Notes (formerly RRA Notes)*, 1988-present; SPRA, 1982[2]; Rahman, 1984; Conway, 1987; Grandin, 1987; KKU, 1987; Scrimshaw and Hurtado, 1987; Rocheleau et al, 1989; NES/CU/EU/WRI, 1990; Rhoades, 1990; Campbell and Gill, 1991; Mascarenhas et al, 1991; Chambers, 1994a, 1994b, 1994c; IDS/IIED, 1994; Pretty et al, 1995). Many have been drawn from a wide range of non-agricultural contexts, and were adapted to new needs. Others are innovations arising out of situations where practitioners have applied the methods in a new setting, the context and people themselves giving rise to the novelty.

There are now more than 30 different terms for these systems of learning and action, some more widely used than others.[3] Participatory Rural Appraisal (PRA), for example is now practised in at least 130 countries, but Samuhik Brahman is associated just with research institutions in Nepal, and REFLECT just with adult literacy programmes. But this diversity and complexity is a strength. It is a sign of both innovation and ownership. Despite the different contexts in which these approaches are used, there are important common principles uniting most of them. These systems emphasize the following six elements:

1 *A Defined Methodology and Systemic Learning Process* – the focus is on cumulative learning by all the participants and, given the nature of these approaches as systems of inquiry and interaction, their use has to be participative. The emphasis on visualizations democratizes and deepens analysis.
2 *Multiple Perspectives* – a central objective is to seek diversity, rather than characterize complexity in terms of average values. The assumption is that different individuals and groups make different evaluations of situations, which lead to different actions. All views of activity or purpose are heavy with interpretation, bias and prejudice, and this implies that there are multiple possible descriptions of any real-world activity.
3 *Group Learning Process* – all involve the recognition that the complexity of the world will only be revealed through group inquiry and interaction. This implies three possible mixes of investigators, namely those from different disciplines, from different sectors, and from outsiders (professionals) and insiders (local people).
4 *Context Specific* – the approaches are flexible enough to be adapted to suit each new set of conditions and actors, and so there are multiple variants.
5 *Facilitating Experts and Stakeholders* – the methodology is concerned with the transformation of existing activities to try to bring about changes which people in the situation regard as improvements. The role of the 'expert' is best thought of as helping people in their situation carry out their own study and so achieve something.
6 *Leading to Sustained Action* – the learning process leads to debate about change, and debate changes the perceptions of the actors and their readiness to contemplate action. Action is agreed, and implementable changes will therefore represent an accommodation between the different conflicting views. The debate and/or analysis both defines changes which would bring about improvement and seeks to motivate people to take action to implement the defined changes. This action includes local institution building or strengthening, so increasing the capacity of people to initiate action on their own.

The participatory methods (sometimes called tools, techniques or instruments[4]) used in these systems of learning and action can be structured into four classes: methods for group and team dynamics, for sampling, for interviewing and dialogue, and for visualization and diagramming (Table 7.2). It is the collection of these methods into unique approaches, or assemblages of methods, that constitute different systems of learning and action.

Participation calls for collective analysis. Even a sole researcher must work closely with local people (often called 'beneficiaries', 'subjects', 'respondents' or 'informants'). Ideally, though, teams of investigators work together in interdisciplinary and intersectoral teams. By working as a group, the investigators can approach a situation from different perspectives, carefully monitor one another's work, and carry out a variety of tasks simultaneously. Groups can be powerful when they function well, as performance and output is likely to be greater than the sum of its

Table 7.2 *Participatory methods for alternative systems of learning and action*

Group and team dynamics methods	*Sampling methods*	*Interviewing and dialogue*	*Visualization and diagramming methods*
• Team contracts • Team reviews and discussions • Interview guides and checklists • Rapid report writing • Energisers • Work sharing (taking part in local activities) • Villager and shared presentations • Process notes and personal diaries	• Transect walks • Wealth ranking and well-being ranking • Social maps • Interview maps	• Semi-structured interviewing • Direct observation • Focus groups • Key informants • Ethnohistories and biographies • Oral histories • Local stories, portraits and case studies	• Mapping and modelling • Social maps and wealth rankings • Transects • Mobility maps • Seasonal calendars • Daily routines and activity profiles • Historical profiles • Trend analyses and time lines • Matrix scoring • Preference or pairwise ranking • Venn diagrams • Network diagrams • Systems diagrams • Flow diagrams • Pie diagrams

individual members. Many assume that simply putting together a group of people in the same place is enough to make an effective team. This is not the case. Shared perceptions, essential for group or community action, have to be negotiated and tested. Yet, the complexity of multidisciplinary team work is generally poorly understood. A range of workshop and field methods can be used to facilitate this process of group formation.

In order to ensure that multiple perspectives are both investigated and represented, practitioners must be clear about who is participating in the data-gathering, analysis and construction of these perspectives. Communities are not homogenous entities, and there is always the danger of assuming that those participating are representative of all views. There are always differences between women and men, between poor and wealthy, between young and old. Those missing, though, are usually the socially marginalized (see Rocheleau, 1991; Guijt and Kaul Shah, 1995). Rigorous sampling is, therefore, an essential part of these participatory approaches, and a range of field methods is available.

Sensitive interviewing and dialogue are a third element of these systems of participatory learning. For the reconstructions of reality to be revealed, the conventional dichotomy between the interviewer and respondent should not be permitted to develop. Interviewing is, therefore, structured around a series of methods that promote a sensitive dialogue. This should appear more like a structured conversation than an interview.

The fourth element is the emphasis on diagramming and visual construction. In formal surveys, information is taken by interviewers, who transform what people say into their own language. By contrast, diagramming can give local people a share in the creation and analysis of knowledge, providing a focus for dialogue which can be sequentially modified and extended. Local categories, criteria and symbols are used during diagramming, which include mapping and modelling, comparative analyses of seasonal, daily and historical trends, ranking and scoring methods to understand decision making, and diagrammatic representations of household and livelihood systems. Rather than answering questions which are directed by the values of the researcher, local people are encouraged to explore their own versions of their worlds. Visualizations, therefore, help to balance dialogue and increase the depth and intensity of discussion.

These alternative methodologies imply a process of learning leading to action. A more sustainable agriculture, with all its uncertainties and complexities, cannot be envisaged without a wide range of actors being involved in continuing processes of learning. Some of the changes underway are remarkable. In a growing number of government and non-government institutions, extractive research is being supplemented by investigation by local people themselves. Participatory methods are being used not just for local people to inform outsiders, but also for people's own analyses of their own conditions (Pretty and Chambers, 1993; Chambers, 1994a, 1994b, 1994c).

The contrast between systems of learning that involve a wider community than just scientists is illustrated by a recent example from the development of the Landcare movement in Australia (Woodhill, 1993; Campbell, 1994b). Jim Woodhill (1993, p1) put it this way: 'Scientists had been monitoring the problem [salinity] for along time and producing a range of publications to inform farmers. What was now significant was the way the farmers talked about the dramatic impact "doing their own science" had on their understanding, motivation to act, and willingness to engage in more fruitful ways with the "experts".'

The Trustworthiness of Findings

It is common for users who have presented findings arising from the use of participatory methods to be asked a question along the lines of 'but how does it compare with the real data?' (see Gill, 1991, p5). It is commonly asserted that participatory methods constitute inquiry that is undisciplined and sloppy. It is said to involve only subjective observations and so reflect just selected members of communities. Terms like informal and qualitative are used to imply poorer quality or second-rate work. Rigour and accuracy are assumed, therefore, to be in contradiction with participatory methods.

This means that it is the investigators relying on participatory methods who are called upon to prove the utility of their approach, not the conventional investigator. Conventional research uses four criteria in order to persuade their audiences that the findings of an inquiry can be trusted (see Lincoln and Guba, 1985; Guba and Lincoln, 1989). How can we be confident about the 'truth' of the findings (internal validity)? Can we apply these findings to other contexts or with other groups of people (external validity)? Would the findings be repeated if the inquiry were replicated with the same (or similar) subjects in the same or similar context (reliability)? How can we be certain that the findings have been determined by the subjects and context of the inquiry, rather than the biases, motivations and perspectives of the investigators (objectivity)? These four criteria, though, are dependent for their meaning on the core assumptions of the conventional research paradigm (Cook and Campbell, 1979; Lincoln and Guba, 1985; Kirk and Miller, 1986).

Trustworthiness criteria were first developed by Guba (1981) to judge whether or not any given inquiry was methodologically sound. Four alternative, but parallel, criteria were developed: credibility, transferability, dependability and conformability. But these '*had their foundation in concerns indigenous to the conventional, or positivist, paradigm*' (Lincoln, 1990, p71). To distinguish between elements of inquiry that were not derived from the conventional paradigm, further 'authenticity' criteria have been suggested to help in judging the impact of the process of inquiry on the people involved (Lincoln, 1990). Have people been changed by the process? Have they a heightened sense of their own constructed realities? Do they have an increased awareness and appreciation of the constructions of other stakeholders? To what extent did the investigation prompt action?

Drawing on these, and other suggestions for 'goodness' criteria (Marshall, 1990; Smith, 1990), a framework of 12 criteria for establishing trustworthiness have been identified (Pretty, 1994).

1. *Prolonged and/or Intense Engagement Between the Various Actors*
   For building trust and rapport, learning the particulars of the context, and keeping the investigator(s) open to multiple influences. Trust takes a long time to build, but can be destroyed overnight. It is increased by confirming that participants will have an input into, and so influence, the learning process.
2. *Persistent and Critical Observation*
   For understanding both a phenomenon and its context. Observation increases the depth of understanding and breadth of realities encountered.
3. *Parallel Investigations and Team Communications*
   If subgroups of the same team proceed with investigations in parallel using the same methodology, and come up with the same or similar findings, then

these findings are trustworthy. This requires regular formal meetings and agreed group norms of behaviour.

4 *Triangulation by Multiple Sources, Methods and Investigators*
For cross-checking information and increasing the range of peoples' realities encountered, including multiple copies of one type of source or different copies of the same information; comparing the results from a range of methods; and having teams with a diversity of personal, professional and disciplinary backgrounds.

5 *Analysis and Expression of Difference*
For ensuring that a wide range of different actors are involved in the analysis, and that their perspectives are accurately represented. These perspectives will not be resolved to a single consensus position.

6 *Negative Case Analysis*
For sequential revision of hypotheses as insight grows, so as to revise until one set of hypotheses accounts for all known cases.

7 *Participant Checking*
For testing the data, interpretations and conclusions with people with whom the original information was constructed and analysed. Participants have the opportunity to investigate discrepancies and challenge findings, to volunteer additional information, and to hear a summary of what investigators have learning and constructed. Without participant checks, investigators can make no claims that they are representing participants' views.

8 *Peer or Colleague Checking*
Periodical reviews with peers or colleagues not directly involved in the learning process, so as to expose investigators to searching questions.

9 *Reports with Working Hypotheses, Contextual Descriptions and Visualizations*
These are 'thick' descriptions of complex reality, with working hypotheses, visualizations and quotations capturing peoples' personal perspectives and experiences.

10 *Reflexive Journals*
These are diaries individuals keep on a daily basis to record a variety of information about themselves and sequential changes in methodology.

11 *Inquiry Audit*
The team should be able to provide sufficient information for a disinterested person to examine the processes and product in such a way as to confirm that the findings are not figments of their imaginations.

12 *Impact on Stakeholders' Capacity to Know and Act*
For demonstrating that the investigation has had an impact, including participants having a heightened sense of their own realities, as well as an increased appreciation of those of other people. The report could also prompt action on the part of readers who have not been directly involved.

These criteria can be used to judge quality, just as statistical analyses provide the grounds for judgement in positivist or conventional science. An application of an alternative system of learning without, for example, triangulation of sources, methods and investigators and participant checking of the constructed outputs, should be judged as untrustworthy. It will never be possible, however, to be certain about the trustworthiness criteria. Certainty is only possible if we fully accept the positivist paradigm. The criteria themselves are value-bound, and so we cannot say that 'x has a trustworthiness score of y points', but we can say that x is trustworthy because certain things happened during and after the investigation. The trustworthiness criteria should be used to identify what has been part of the process of generating information, and whether key elements have been omitted. Knowing this should make it possible for any observer, be they reader of a report or policy maker using the information to make a decision, also to make a judgement on whether they trust the findings. In this context, it becomes possible to state that the 'data no longer speak for themselves'.

Towards a New Professionalism

The elements of these systems of participatory learning, the values, principles, methods and trustworthiness criteria, will not be sufficient to provoke widespread change in institutions and individuals. The methods themselves are not neutral of historical, social and political context. They may be used to lead to genuine local capacity building and organisation, or they may be used to satisfy external objectives alone.

These systems of learning are centred on approaches that are alternatives to positivism. They are more likely to generate information already agreed and negotiated by various interest groups. As a result, the likelihood of conflicts is reduced. For these reasons, they can be good for decision makers, as the needs and values are explicit: 'inquiry that purports to be value-free is probably the most insidious form of inquiry available because its inherent but unexamined values influence policy without ever being scrutinized themselves' (Lincoln, 1990, p82, quoting Beardsley, 1980). However, there will never be any final, correct answers. There is no absolute trustworthiness, only trustworthiness for a given time in a given context. Furthermore, because all the actors can be said to trust a particular body of information at a particular time, this does not mean to say they will always do so. As external conditions change, so their values and criteria for judging will also change. The information may then come to be judged as untrustworthy, with various people no longer having confidence in it.

It will be important to ensure the construction and generation of timely, relevant, agreed information and knowledge that will support the quest towards a sustainable agriculture. This raises two challenges: finding ways of developing both new institutional arrangements and alliances to encourage greater learning and wider peer involvement; and a whole new professionalism with greater understanding of the range of scientific methodologies and an emphasis on the process of learning (and unlearning) itself.

The central concept of sustainable agriculture is that it must enshrine new ways of learning about the world. Such learning should not be confused with 'teaching'. Teaching implies the transfer of knowledge from someone who knows to someone who does not know, and is the normal mode of educational curricula (Ison, 1990; Argyris, 1991; Russell and Ison, 1991; Bawden, 1992, 1994; Pretty and Chambers, 1993). Universities and other professional institutions reinforce the teaching paradigm by giving the impression that they are custodians of knowledge which can be dispensed or given (usually by lecture) to a recipient (a student). Where teaching does not include a focus on self-development and enhancing the ability to learn, then 'teaching threatens sustainable agriculture' (Ison, 1990).

A move from a teaching to a learning style has profound implications for agricultural development institutions. The focus is less on *what* we learn, and more on *how* we learn and *with whom*. This implies new roles for development professionals, leading to a whole new professionalism with new concepts, values, methods and behaviour (Table 7.3). Typically, normal professionals are single-disciplinary, work largely in ways remote from people, are insensitive to diversity of context, and are concerned with themselves generating and transferring technologies. Their beliefs about people's conditions and priorities often differ from people's own views. The new professionals, by contrast, make explicit their underlying values, select methodologies to suit needs, are more multidisciplinary and work closely with other disciplines, and are not intimidated by the complexities and uncertainties of dialogue and action with a wide range of non-scientific people (Pretty and Chambers, 1993).

But it would be wrong to characterize this as a simple polarisation between old and new professionalism, implying in some way the bad and the good. True sensibility lies in the way opposites are synthesized. It is clearly time to add to the paradigm of positivism for science, and embrace the new alternatives. This will not be easy. Professionals will need to be able to select appropriate methodologies for particular tasks (Funtowicz and Ravetz, 1993). Where the problem situation is well defined, system uncertainties are low, and decision stakes are low, then positivist and reductionist science will work well. But where the problems are poorly defined and there are great uncertainties potentially involving many actors and interests, then the methodology will have to comprise these alternative methods of learning. Many existing agricultural professionals will resist such paradigmatic changes, as they will see this as a deprofessionalization of research. But Hart (1992, p19) has put it differently: 'I see it as a "re-professionalisation", with new roles for the researcher as a democratic participant.'

A systematic challenge for agricultural and rural institutions, whether government or non-government, is to institutionalize these approaches and structures that encourage learning. Most organizations have mechanisms for identifying departures from normal operating procedures. This is what Argyris (1991) calls single-loop learning. But most institutions are very resistant to double-loop learning, as this involves the questioning of, and possible changes in, the wider values and procedures under which they operate. For organizations to become learning

Table 7.3 *Towards a new professionalism for sustainable agriculture*

Elements	*Components of the new professionalism*
Assumptions about reality	The assumption is that realities are socially constructed, and so participatory methodologies are required to relate these many and varied perspectives one to another
Underlying values	Underlying values are not presupposed, but are made explicit; old dichotomies of facts and values, and knowledge and ignorance, are transcended
Scientific method(s)	The many scientific methods are accepted as complementary; with reductionist science for well-defined problems and when system uncertainties are low; and holistic and constructivist science when problem situations are complex and uncertain
Who sets priorities and whose criteria count?	A wide range of stakeholders and professionals set priorities together; local people's criteria and perceptions are emphasized
Context of researching process	Investigators accept that they do not know where research will lead; it has to be an open-ended learning process; historical and spatial context of inquiry is fundamentally important
Relationship between actors and groups in the process	Professionals shift from controlling to enabling mode; they attempt to build trust through joint analyses and negotiation; understanding arises through this interaction, resulting in deeper relationships between investigator(s), the 'objects' of research, and the wider communities of interest
Mode of professional working	More multidisciplinary than single disciplinary when problems difficult to define; so attention is needed on the interactions between members of groups working together
Institutional involvement	No longer just scientific or higher-level institutions involved; process inevitably comprises a broad range of societal and cultural institutions and movements at all levels
Quality assurance and evaluation	There are no simple, objective criteria for quality assurance: criteria for trustworthiness replace internal validity, external validity, objectivity and reliability when methods is non-reductionist; evaluation is no longer by professionals or scientists alone, but by a wide range of affected and interested parties (the extended peer community)

Source: Adapted from Pretty and Chambers (1993)

organizations, they must ensure that people become aware of the way they learn, both from mistakes and from successes.

Institutions can, therefore, improve learning by encouraging systems that develop a better awareness of information. The best way to do this is to be in close touch with external environments, and to have a genuine commitment to participative decision making, combined with participatory analysis of performance. Learning organizations will, therefore, have to be more decentralized, with an open multidisciplinarity, and heterogeneous outputs responding to the demands and needs of farmers. These multiple realities and complexities will have to be understood through multiple linkages and alliances, with regular participation between professional and public actors. It is only when some of these new professional norms and practices are in place that widespread changes in the livelihoods of farmers and their natural environments are likely to be achieved.

Acknowledgements

An earlier version of this article benefited from many insights arising from discussions with colleagues and from practical issues arising during many training workshops. I am particularly grateful to David Blacket, Andrew Campbell, Robert Chambers, John Devavaram, Irene Guijt, Sam Joseph, Charles Lane, Neela Mukherjee, Michel Pimbert, Niels Röling, David Satterthwaite, John Thompson, Alice Welbourn and Jim Woodhill, together with three anonymous referees, for comments on earlier versions of this article. Any errors, omissions and misleading statements are, of course, solely my responsibility.

Notes

1 Alternatives, additions and challenges to the positivist paradigm have emerged from a very wide range of disciplines, including from chaos theory and non-linear science (Prigogine and Stengers, 1984; Gleick, 1987; Gould, 1989); fractal geometry and mathematics (Family and Vicsek, 1991; Lorenz, 1993); quantum physics (see many sources, but especially theories of Schrödinger and Heisenberg); neural networks (Holland et al, 1986); soft-systems science (Checkland, 1981, 1989; Checkland and Scholes, 1990; Röling, 1994); post-normal science (Funtowicz and Ravetz, 1993); philosophy of symbiosis (Kurokawa, 1991); historical sociology (Abrams, 1989); morphic resonance (Sheldrake, 1988); popular epidemiology (Brown, 1987); complexity theory (Waldrop, 1992; Santa Fe Institute, *passim*); Gaia hypothesis (Lovelock, 1979); alternative economics (Arthur, 1989; Daly and Cobb, 1989; Ekins, 1990; Douthwaite, 1992); post-positivism (Phillips, 1990); critical systems theory (Popkewitz, 1990; Jackson, 1991; Tsoukas, 1992); constructivist inquiry (Denzin, 1984; Lincoln and Guba, 1985; Röling and Jiggins, 1994; Engel, 1995); communicative action (Habermas, 1987); postmodernism (Harvey, 1989); adaptive management and operationality in turbulence (Holling, 1978; Norgaard, 1989; Mearns, 1991; Roche, 1992; Uphoff, 1992); learning organizations and clumsy institutions (Argyris and Schön, 1978; Peters, 1987; Handy, 1989; Shapiro, 1988; Thompson and Trisoglio, 1993); and social ecology (Bawden, 1991, 1994; Woodhill, 1993).

2 This list of references cannot possibly be comprehensive, as the antecedents and actors involved are too numerous to mention. The informal journal *PLA Notes (formerly RRA Notes)* (in issues 1 to 22) has alone published 240 articles since 1988 based on field experiences in rural and urban communities in some 55 countries; and the IDS/IIED (1994) annotated bibliography contains a listing of some 600 references relating to Participatory Rural Appraisal (PRA) and Rapid Rural Appraisal (RRA).

3 A selection of recently emerged terms of alternative systems of learning and action include Agroecosystems Analysis (AEA), Beneficiary Assessment, Development Education Leadership Teams

(DELTA), Diagnóstico Rurale Participativo (DRP), Farmer Participatory Research, Farming Systems Research, Groupe de Recherche et d'Appui pour l'Auto-Promotion Paysanne (GRAAP), Méthode Accélérée de Recherche Participative (MARP), Participatory Analysis and Learning Methods (PALM), Participatory Action Research (PAR), Participatory Research Methodology (PRM), Participatory Rural Appraisal (PRA), Participatory Rural Appraisal and Planning (PRAP), Participatory Technology Development (PTD), Participatory Urban Appraisal (PUA), Planning for Real, Process Documentation, Rapid Appraisal (RA), Rapid Assessment of Agricultural Knowledge Systems (RAAKS), Rapid Assessment Procedures (RAP), Rapid Assessment Techniques (RAT), Rapid Catchment Analysis (RCA), Rapid Ethnographic Assessment (REA), Rapid Food Security Assessment (RFSA), Rapid Multi-perspective Appraisal (RMA), Rapid Organisational Assessment (ROA), Rapid Rural Appraisal (RRA), Regenerated Freiréan Literacy through Empowering Community Techniques (REFLECT), Samuhik Brahman (Joint trek), Soft Systems Methodology (SSM), Theatre for Development, Training for Transformation, and Visualisation in Participatory Programmes (VIPP).

4 These terms, 'tool', 'technique' and 'instrument', imply a functionality that does not exist in practice. A tool, such as a screwdriver, guarantees an output from an input; a technique, such as how to join together two pieces of wood, is something that can be repeated by skilled practitioners; an instrument, such as a compass, unerringly measures and indicates. No participatory methods can guarantee outputs from given inputs as they involve the activities of diverse social actors, whose interests and concerns cannot be predicted in advance (see Checkland, 1989).

Past, Present and Future

J. D. Van der Ploeg

We generally imagine society, and the practices and processes localized in it, as ordered by historically rooted patterns and relationships. Yet this idea, found in and promoted particularly by the social sciences, is increasingly open to challenge. Indeed, this idea becomes an obstacle to an adequate understanding of social processes and developments. However improbable it seems at first, contemporary society is increasingly ordered in a roundabout way – that is, via the future.

Human activity is always and everywhere future oriented. *Somos lo que vamos a ser*, we are what we are becoming, according to Ortega y Gasset (1995, p277).[1] This does not pre-empt the fact that the relations between past, present, and future are subject to radical changes. The way in which future-oriented actions are constituted and founded has changed drastically.

Within societies that are generally regarded as traditional, the future was understood, and subsequently created, as a repetition of the past. Previously acquired experiences plotted the course of the future. By pursuing that course in the present, the future became a repetition of past relations. The past was reproduced via the present through collective memory, through the fear of deviating from it, as well as through the convenience of the tried and true. Thus emerged a straight and above all narrow road, running from the past, via the present, to the future. A crucial role was played by what sociologists call *Gemeinschaft*. Well-defined norms applied to the levels of community, family, village and vocational group. One had to act according to norms reflecting what was well tried, what was historically just. Deviation resulted in sanctions.

A radical change was introduced into this initially monotonous scheme, during the period defined as the age of modernization.[2] The past turned from guiding principle to starting point, to be built upon in various ways; no longer according to the strict rules inherent to the *Gemeinschaft*, but according to new degrees of freedom applying to the *Gesellschaft*: people belonged to a class, to a society, they were part of markets, and they shared in the blessings of technical development.

Reprinted from Van der Ploeg J D. 2003. Past, present and future. In *The Virtual Farmer*, Royal van Gorcum Assen, Netherlands. Chapter 1, pp3–48.

On the one hand, this new constellation introduced an often considerable set of limitations; on the other hand, it accommodated further unfolding and unfurling. Starting out from the foundations created in the past – and embodied in particular practices, resources, knowledges, and opportunities – various roads were developed towards a future that could be understood as a multifaceted process of unfolding the potentialities situated in what had been established so far (Kosik, 1976).

Thus, the present became an important link. It had been built on the past in specific and often contrasting ways. Hence, the future appeared as a vast array of possibilities – that is, those possibilities contained in the present to be utilized and realized subsequently.

At the moment, we already have one foot in an ensuing constellation,[3] which I will call, for the sake of convenience, the postmodern. In this constellation, the future is no longer the multifaceted utilization and unfolding of development opportunities situated in the present. Instead, the future becomes a beacon, strongly conditioning contemporary actions. If future-oriented actions were initially based in the routines of the past and later became founded on, and hence defined by, the opportunities located in the present – today, the construction of the future is systematically disconnected from both. History becomes almost irrelevant, and the present is reduced to merely a (more or less favourable) run-up to the future. The burning questions are who, or what, will in which way, construct the guiding images of the future.

All in all, the moment of ordering has shifted dramatically. Initially, this moment was hidden in history (for the future could not be anything but a repetition of the past). Collective memory, with its defined normative frame, constituted the moment of ordering par excellence. Later, in the age of modernization, the moment of ordering shifted to the present: even though the past was still built on, the way in which this happened was highly variable. The present became an essential, albeit highly variable, link between past and future. Taking the former achievements into consideration, one chose and realized multiple roads to the future. Thus the future became freed from its ties with the past.

If every moment represented a particular reality, it also contained various development opportunities, various routes to the future. Of course, of all those possibilities, only one could be realized in any given situation. Agency – that is, the capacity to achieve something – became decisive in this dance from reality to the future.

At present, the ordering moment is, to a large extent, located with those[4] who are able to specify where we are heading. However astonishing this may initially seem, images of the future almost irresistibly determine what we do today.

Social developments and practices are increasingly ruled and directed by such images of the future. In a way, the present becomes shackled by the limited and compelling images of the future that we create; for these images of the future define what is, in the here and now, sensible and rational and also what is absurd and irrational.

Remarkably, and in sharp contrast to the previous phase, these are no longer multiple and mutually contradistinctive images of the future (every one of which can potentially be realised) but instead they are compelling and exclusive. Only one option is regarded as feasible and legitimate. If a certain reality contained various alternatives in the past, now one single option acts as the selective frame in defining the preferred (or unavoidable) future reality. Institutionalized images of the future have become the pre-eminent moments of ordering. The expert systems that have emerged in recent decades are the most important carriers of this process.

Megaprojects (see Scott, 1998)[5] now constitute the largely contested, but still highly imperative frames that orient the actions of various actors towards one set of parameters: towards the future constellation that facilitates 'profits' and in which it is better to participate than to stand aside. Expert systems are crucial in constituting these megaprojects.

A similar development can be encountered in the markets. The most important markets no longer deal with commodities that are produced and traded here and now – they are concerned with the future. On option markets (and on stock markets) 'trade' is in expectations: trade is about the opportunity to supply and sell a certain commodity at a future price. The same applies to stock markets: they are inspired and constituted by expectations about future profits. Crucial in all this is that the actual trade taking place at present is dominated by the trade in expectations.

Figure 8.1 summarizes this argument. In traditional society (1a) past, present, and future were in alignment with each other. In modern society (1b) the present contains a series of alternatives. Starting from currently available resources various prospects can be realised. Finally, in postmodern society (1c) 'disciplining' originates from the future. Only one future is considered possible, to which present practices are subordinated. Future resources, rather than current ones, become critical.

Types of Social Cohesion

The crucial cement in traditional societies is constituted by what is tried and true. Everyday life is shaped by faith in what are well-tried routines, and by faith in those organisations and individuals that embody and/or express this faith most adequately. Social practices are ordered through such faith – similarly, the compass is oriented to the past via this faith in what is familiar and well-tried; thus the past is carried towards the future, via the present.

In other words, the habit of drawing on the repertoire of what is tried and true emerges here as one of the most important ordering principles (or, following Law (1994), one of the most important 'modes of ordering'). The normative frame – 'do as we always have done because it is right in itself – is the foremost medium for maintaining the continuity that connected past, present and future. It provided social cohesion.

In modernizing societies, this normative moment, which focuses on what is tried and true, is replaced by agency: the ability to realize one's own future projects.

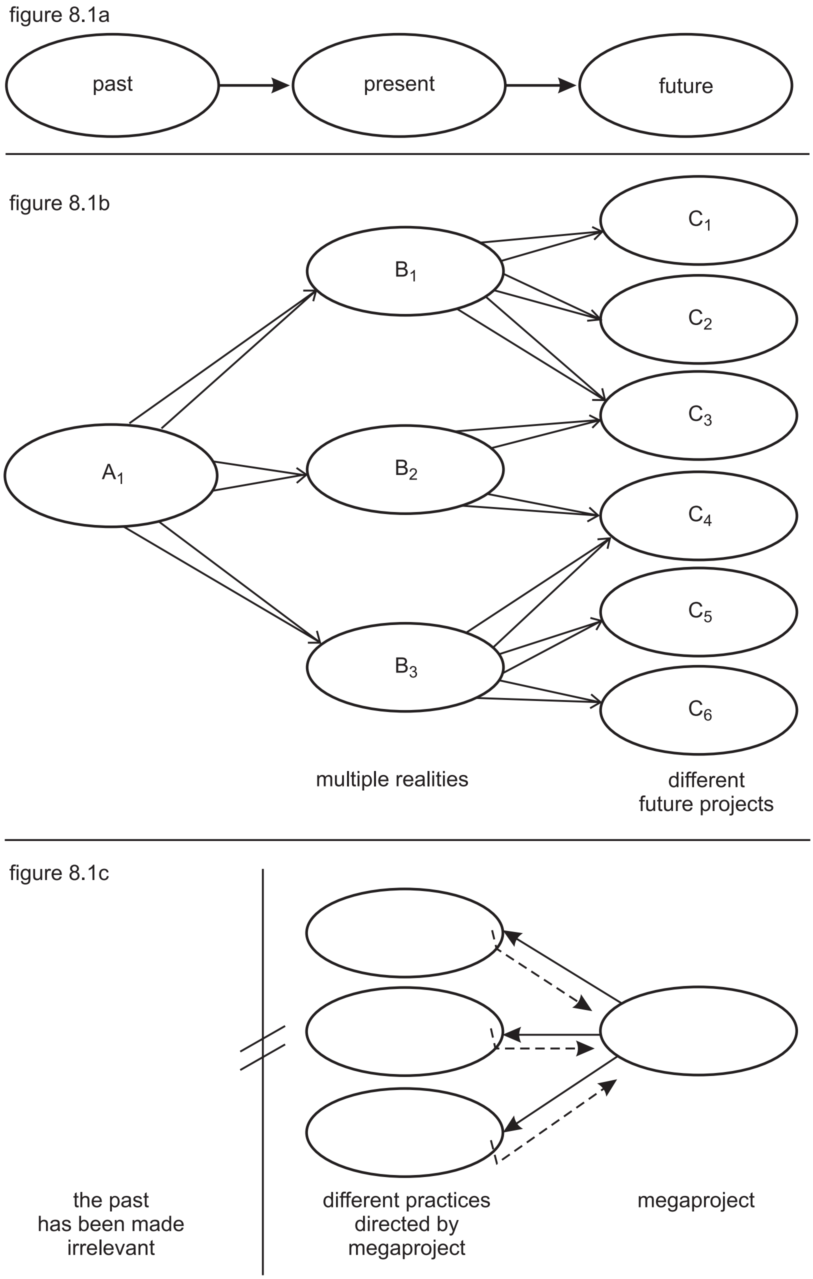

Figure 8.1 *The relations between past, present and future*

Here too faith is a vital ingredient, yet this is no longer the same faith that once was the cement of traditional societies. Now it is confidence in one's own knowledge and capacity. Integral to all this is confidence in the realization of new alternatives that build on the resources developed thus far and in the ability to develop the required connections with others.

Thanks to agency, the various projects of Figure 8.1b can be realized. The question of what is possible is always crucial. Knowledge (whatever the type) of new possibilities that reach beyond both what is well-tried and what is considered right becomes a decisive factor. Knorr-Cetina provides an accurate definition of the difference between these two phases:

> *Not only has order become a cognitive (including linguistic) rather than a normative phenomenon, it has also become a man-made rather than a man-coercing matter: it is produced, contested, repaired, organised and displayed in concrete situations whose definition became the subject of continual accomplishment and interruption* (1981, p6).

Increasing differentiation is characteristic of 'order as a man-made matter'. Available resources (both material and social) are unfolded and developed in increasingly different ways. Hence, different and mutually contrasting realities (multiple realities) emerge, each providing their own starting points for further evolution. Apart from the social, the material too produces an ordering effect.[6]

In retrospect, the high degree of institutional clustering that seems to rule the contemporary, postmodern world was largely absent in modernizing societies. At present a semi-coherent system of artefacts, rules, procedures, agendas and expectations – in short a technological regime (Rip, 1995; Rip and Kemp, 1998) – directs, informs and sanctions social actions to an extent that can almost be described as coercive. In contrast, a much more diffuse process of variation and selection was in operation during the modernization phase. New development opportunities (such as those represented in Figure 8.1b) were not judged a priori by the degree to which they were in alignment with dominant development projects. Variation originated from every nook and cranny. The evolving practices themselves formed the basis for the judgement of what was 'better' and what was 'worse'.[7] Variation increased and selection followed later. The selection was *ex post* and essentially made by the parties that were directly involved.

These ongoing processes of variation and selection merit further discussion. First, the unfolding of development opportunities – that is, the pursuit of particular development projects – should not be understood as a mere individualistic enterprise. Just as the actions (of any individual actor) can only be understood as the concomitance (interlocking)[8] of and/or distantiation[9] from different practices, individual projects can only be realized if they are founded in the required degree of coordination – that is, if they become part of a larger system of interlocking projects. Actor-networks are crucial in this.[10]

This is illustrated in Figure 8.2. Actor A only has a chance of realizing their specific development project if they succeed in realizing the essential convergence with B's and C's development projects at the right time. Say, B and C stand for the dairy industry and a neighbouring farmer, respectively. So far, A has had little to do with C (there is currently no interaction). However, since A's 'project' anticipates a

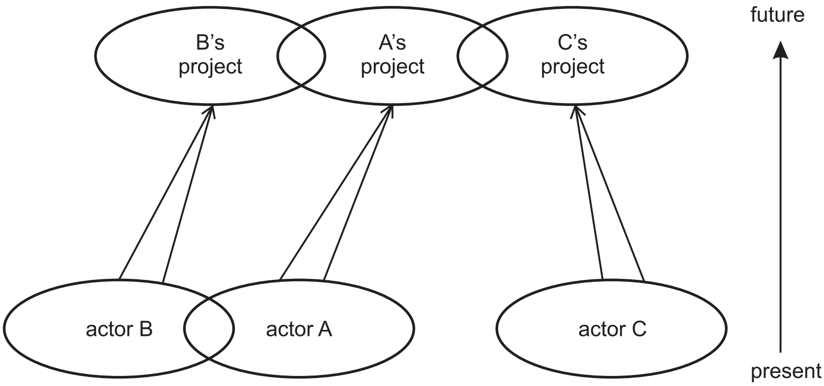

Figure 8.2 *The convergence of projects*

rapid expansion (more land, more quota, more room for ammonia emissions etc.), partly because this is expected by B, the future disappearance of C (and hence the transfer of development opportunities from C to A) can be crucial for the realization of A's development project.

The degree to which convergence of development projects is created thus emerges as one of the most important ordering principles.

> *Instead of being seen as a monolithic system which regulates individual action, order comes to be seen as an upshot of concrete, communicative interaction [...] Social order is not that which holds society together by somehow controlling individual wills, but that which comes about in the mundane but relentless transactions of these wills* (Knorr-Cetina, 1981, p7).

In the postmodern constellation, a new 'cement', a new mechanism for maintaining cohesion can be identified: trust.[11] Trust refers to the necessity to follow more or less implicitly, and to rely on, a system of objectified parameters defining rational versus irrational alternatives for action. In this context Galjart (1998, p13) speaks of 'trust in systems'.[12] As social cement, trust contrasts sharply with the normative and cognitive mechanisms discussed above. What may, and should be, proved is defined by new frames. The (decentralized) production of multifarious knowledge becomes replaced by a new approach: how to organize knowledge in a centralized way. This requires a particular carrier.[13] If collective memory and widely supported normative frames were initially important and later replaced by the capacity *to make a difference*, as supported by various and varying groups of actors – trust is accompanied by a new carrier, the expert system. That is:

> *a system of technical accomplishment [and] professional expertise that organises large areas of the material and social environments in which we live today* (Giddens, 1990, p27).

Figure 8.1c illustrates how a certain (as yet not existing) image of the future is specified within, and through, the expert system. Only later will the means and rules through which this image will be designed and implemented become evident. This realization takes place via the simultaneous coordination of various, apparently unconnected, practices. The extent to which such a coordination occurs depends directly upon trust, upon the supposed certainty that adjusting one's own actions to the specified image of the future achieves better results than diverting from the image.

The outcome of modern courses of action (see Figure 8.1b) is a highly heterogeneous world, a set of contrasting practices, which, due to a particular organization of interrelationships, collectively compose a system that is able to operate due to the realization of sufficient degrees of freedom for each of the discernible practices.

In the postmodern constellation (see Figure 8.1c), on the other hand, society tends towards uniformity. Since expert systems radically restructure the relations between 'the universe of the undisputed' and the 'universe of discourse' (Bourdieu, 1977, p168) and between what is and what is not allowed, a process of ordering emerges that puts great pressure on, or eliminates, the heterogeneous nature of social relations and practices.

Expert systems create a new 'domain of the undisputed', a new '*habitus*' (Bourdieu, 1990) of their own: that is, a world as it should be; not because there would be some sort of subjectivity or intersubjectivity, but because this 'world', this future, would be determined objectively by laws that are understood in and by the expert system.

Incidentally, it should be mentioned that in the creation of a heterogeneous world the phrase 'everything goes' definitely does not apply: the world cannot be moulded and shaped at will. Co-production and co-evolution always play a key role in the development of the various practices, that collectively compose a 'heterogeneous world'. I use these concepts to refer to the interaction between, and the mutual transformation of, the material and the social. Farming can be understood as a special type of co-production, precisely because here the material largely coincides with the living world.

The living world (animals, crops, soil, ecosystems in the wider sense etc.) is not only exploited by agriculture; it is also continuously unfolded, recombined, enriched and/or depleted by it. In short, the resources that are derived from nature, and which remain part of nature at the same time, are particularized in, and through, farming to contain new, always specific, possibilities but also new, again specific, limitations. In terms of Figure 8.1b: you cannot jump from B1 to C5 just like that. For example a high-yielding Holstein cow cannot suddenly be put on a low-energy diet. In summary, people draw their own boundaries in and through their interaction with nature (that is, through co-production). And where one considers jumping over the boundaries, it emerges sooner or later that the material, and certainly the living world, cannot be understood and treated as if it is as 'malleable as clay'.

Similarly, the social world has its own characteristics. Various examples will be discussed in the course of this book. They are partly related to the particular requirements resulting from co-production: not every form of social organization matches the particular kind of co-production and co-evolution in agriculture. Disregarding those particular requirements (a remarkable characteristic of current expert systems) can result in extreme disruptions and irreversibility (NRLO, 1997; Scott, 1998).

Finally, when expert systems become dominant, in the sense that they reduce the expanding set of future possibilities to one exclusive alternative, selection changes its nature. Then there is no longer concern about an *ex post facto* selection, but rather about an *ex ante* selection: only those actions that correspond with the preferred future count as valid. All the others become delegitimized from the very start. It goes without saying that this has radical and highly negative effects on the production, and maintenance, of variety.

Time, Structure and the Social Sciences

Just as every revolution is decorated with the colours and symbols of the previous revolution (Groen and De Buch, 1968), the social sciences try to unravel existing constellations by using concepts that were developed to understand the previous ones. The modernization period – characterized by its highly differentiated nature, by a process of simultaneous unfolding of various, contrasting projects (see Figure 8.1b) – is usually approached with a concept of structure derived from, and corresponding more closely with, the previous, traditional situation. Central to this concept of structure are causal complexes, which precede certain outcomes (see Figure 8.1a). Because a certain cause cannot produce contrasting effects, the explanation of heterogeneity (see Figure 8.1b) becomes an almost insoluble problem from the outset.

The same is repeated under postmodern relations. Attempts are made to understand practices that are increasingly standardized, if not 'caged', by the dominance of the expert systems (see Figure 8.1c) through the application of an adage better suited for the modern era: 'agency is going beyond structure/structure follows action'. Again, a major problem arises; that is, to understand how convergence, homogenization and coercion increase in an apparently free world.

In all societies, regardless of time and space, regularities and recurring patterns emerge. These regularities constitute the blessing and the curse of the social sciences. They constitute the starting point, but often also the Waterloo, of the enterprises of economists, sociologists and historians.

Such regularities, irrespective of where they occur and of their nature, always lead to a set of interrelated questions, which I will briefly summarize here.

1 To what extent are the observed regularities absolute? What is the importance and relevance of the exceptions, the 'black swans', which, on careful inspection, can generally be found as well? And subsequently, what influence (if not bias) do the methods have with which we construct these regularities? How do we get to determine regularities at all?

2 What do these regularities mean? Do they mark out the undisputed from the discursive, the fixed from what might still be variable? Do they refer to a frame in which human action and, more generally, social development necessarily has to take place?
3 What do the occurring regularities refer to? Do they offer information about underlying structures (irrespective of their nature) imperatively directing human action (and hence social development)? Do they refer to cause–effect relations with which the observed (or constructed) regularities can be regarded as resulting from underlying causal complexes? Or are they rather the expression (and/or representation) of temporally and spatially bounded conventions, which should be considered as fluid and variable?
4 More precisely, how do the different regularities, the different conventions, relate to each other? And maybe even more importantly, what role does our ability and/or inability to gain control over the occurrence of regularities play in the actual ordering of the world?

Social practices contain certain regularities. They follow certain patterns, a certain logic, resulting in a certain course, a certain pattern, becoming self-evident truisms: 'that's just the way it goes'. Observers of the agricultural sector will come across countless, and often impressive, examples of regularities. These are usually examples that reach far beyond specific locations in time and space.

Whatever the place or time, agriculture is generally organized into small units, which we define nowadays as family farms – that is, units in which labour and capital are combined in one and the same person. Farm men and women are not only owners of most of the means of production, they also do most of the productive work. Management as an isolated factor is absent: mental and manual labour are combined in the same person. All this constitutes a remarkable contrast to the industrial organization in the urban economy (Braverman, 1974) where design and implementation, mental and manual labour are usually separated, as are the ownership of the means of production and the realization of the actual labour and production processes.

Other regularities are more confined in terms of time and space. There are periods in which farms are systematically and purposefully reduced in size (Staatscommissie, 1912, pp477, 492), whereas in other periods there seems to be a universal tendency towards farm enlargement. These seem to be almost general processes within the boundaries of the period in question. Someone who looks further into this will recognize the particular and the temporary.

Similarly, regularities are spatially confined. Hayami and Ruttan (1985) show, in a comparative analysis at the global level, how there is ongoing intensification in certain regions, while scale enlargement emerges as the dominant development pattern in others, and stagnation is most striking in others. A similar spatial differentiation can be found even within the European Union, where similar economic relations increasingly apply and where new technologies are basically accessible to every one (Van der Ploeg, 1991, p65).

Why do regularities exist at all? What are their roots? What exactly do they consist of? And why does one pattern sometimes replace another? These essential questions are asked repeatedly within the social sciences and many answers have been offered. In this book I will try to relate these questions to the way in which past, present and future are connected.

Regularities are, to summarize a large part of social science theories, the outcome of a certain ordering: the result of an ordering that, it is often assumed, is produced in the last instance by a certain structure. There are, to summarize further, certain, clearly definable and identifiable structures that order human action, i.e. different social practices.

Structures form the guiding principles for action, they lead action in a certain direction. Hence, regularities emerge, which in turn constitute an argument for further (conformation of the already introduced) ordering: indeed, 'that is just the way it goes'. One can try to set up an industrial farm (based on labour – capital relations), one can try to escape the necessity of farm enlargement, but sooner or later such attempts will fail. The course of history – structural development, as one says in agricultural circles – is irreversible.

Alongside the question of where to locate such a structure (within the predominant mode of production, in the system of norms and values inspiring and informing human action, in the system requirements inherent in every society, within the combination of opportunities and limitations contained in every situation, within the relations situated in markets, in the development of technology, or within the combination of technological and economic development?) the question of how to imagine such a structure emerges. In essence, the latter question leads us to the relation between cause and effect, to the interrelations between past, present and future.

Within the space of this section it is almost impossible to do justice to all that has been said about this issue (for an excellent discussion about the structure concept in agriculture, see Benvenuti, 1990). Therefore, I will confine myself to a simple contrast: the image in which structure is represented as a *skeleton*, as the carrying framework, versus the concept of structure as a *process of ordering*, as that which is being built.

A favourite image represents structure as being like a skeleton. Just as a skeleton shapes the human body (at most one can be fatter or thinner), structure shapes human action. In other words, action is conditioned by structure: certain actions are possible, others are ruled out. I will never be a sprinter with my hip dysplasia.

Apart from the analogy with the human body, reference is frequently made to large-scale constructions: a modern high-rise block of flats contains a framework, a skeleton made of reinforced concrete (Giddens, 1992, pp19, 731). The framework is fixed. Within the possibilities of the framework, only certain rooms and arrangements can be created.

In short, structure is coercive. Certain possibilities are ruled out, while other possibilities present themselves as obvious. Furthermore, structure precedes subsequent actions. Action is determined by structure; and structure precedes action. Hence, structure is in essence external to action.

Structure as process of ordering

As indicated in Figure 8.1b, certain realities contain certain development opportunities, while ruling out others at the same time. In essence, it means that the mobilized resources are shaped, are differentiated, into particular resources. In plain English, a beef cow is not a dairy cow, and it is impossible to change her into a dairy cow overnight.[14] The same goes, for example, for the craftsmanship of a beef farmer; it differs remarkably from a dairy farmer's. By implication, there is little use in abruptly replacing the herd (selling beef cattle, buying dairy cows); the necessary craftsmanship will still be missing. The same applies to the capacities (the 'abilities') of the actors involved: they know how to realize, utilize and further develop certain matters, but not others. And finally, the networks: there are certain relations that can be built upon, while other relations are missing and cannot be developed just like that. It is questionable, for example, whether a dairy factory is willing to accept a new supplier, especially one with no experience of dairy farming.

Further illustration will not be necessary. A particular constellation has been built up, including networks, resources and actors (often summarized in this context in terms of socio-technical networks);[15] a particular 'system' that contains its own development opportunities and rules out others. This particular process of ordering directs and shapes future-oriented action to a large extent, but not so much in the classic, determinist sense. What orders (or 'structures') here is the already constructed practice, not something external to that practice.

Similarly, the situation of the beef farmer (I use the example one more time) contains various distinct possibilities. He or she can gradually develop their farm towards high-quality cattle (focus the use of his resources into one direction) and develop the networks necessary to pursue this goal. However, other options will present themselves too: to continue beef production whilst sharply increasing its scale, et cetera. Whatever alternative is chosen (can be chosen), the process of ordering will always be continued. Ordering is an ongoing process, and a process that largely directs itself. I have summarized this again in more detail in Figure 8.3.

Of course, the unfolding of development opportunities, the realization of a particular project that builds on what is already realized, does not happen in isolation. Whatever possibility is pursued and realized, interactions with the development projects of others will always be at issue. Frequently this will be translated through abstract, depersonalized categories. For example, what developments are taking place in the markets? Of course, these issues are taken into consideration in the unfolding of one's own project. External developments are followed, interpreted and translated into one's own actions, into further-reaching processes of unfolding.

Again we have to conclude that this does not involve unidirectional determination. Not everyone has made himself equally dependent upon external developments, upon other projects. Some meat producers, for instance, will have made extensive use of external funding. They have let their own development project

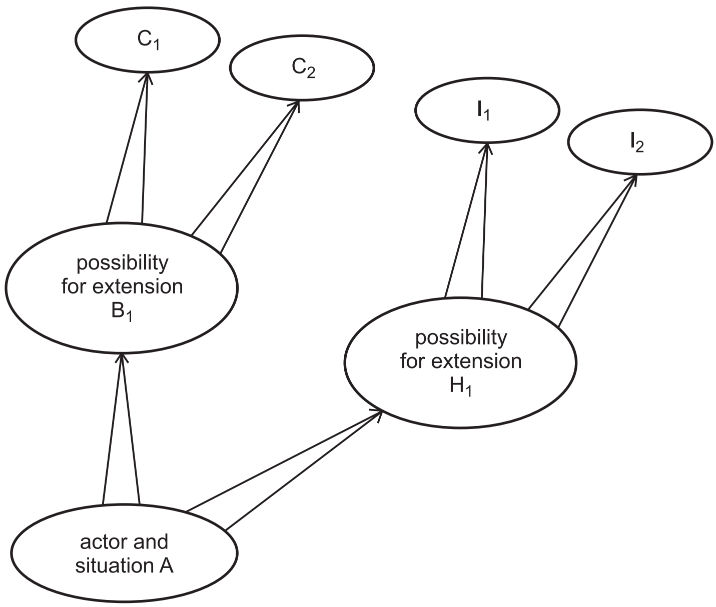

Figure 8.3 *Ongoing process of unfolding*

converge largely with the particular development projects of banks. Consequently, in case of further expansion they have to take account of the parameters applying to capital markets and of the requirements of the funding organizations. This will not apply to other meat producers who have based the construction of their farm on their own savings and/or family capital, or if it does apply it will be less significant.

Analytically, integration and distantiation thus become important key concepts. In more general terms, the network of relationships connecting different projects becomes decisive in the further construction of practices. What is important to note here, however, is that the nature of these networks can vary considerably.

In a way current practices constitute the result of former processes of unfolding. In turn, these practices (the particular and fine-tuned systems of resources, capabilities and networks) direct and order the further processes of unfolding, which will undoubtedly leave their mark on subsequent possibilities and impossibilities. That which has been constructed in a certain practice structures the further development of that practice. Hence, regularities emerge: patterns of coherence and continuity. In turn, they refer indeed to something that orders, to something that structures. In other words, there is absolutely no need to deny that 'actors' choices can be constrained' (Harriss, 1997, p11).[16]

Essentially, that which structures is not external to, but inherent and implicit in, the practices themselves – that is, in the practices that the actors involved realize themselves, in mutual interaction with others and with other things. In essence outside of these social practices (in their broadest sense) there is no other structure that orders these practices as a given 'skeleton'.[17] The structuring element is contained in the practices themselves: in the unfolding and, therefore, in that which is unfolded. To unfold is to structure, and structuring takes place through processes of unfolding. This is not to deny the influence of distant practices, of practices situated elsewhere, or the influence of 'interactive systems over which they [i.e. the actors involved] have little control' (Booth, 1994, p39).[18] In so far as such 'interactive systems' (or 'networks' as I have defined them above) and external parameters, such as the interest rate, given in the previous example, exert any influence this will occur through the interaction between the 'internal' and the 'external' – never unilaterally and deterministically from the 'external'.[19]

Agency – the capability 'to make a difference' – and networks are two essential concepts in the development of a non-determinist concept of structure as construction, of structure as situated, and inherent, in social practices – hence, of structure as a heterogeneous and evolving phenomenon.

The concept of agency occupies a prominent position in contemporary sociology. According to Giddens:

> *Agency refers not to the intentions people have in doing things but to their capability of doing things in the first place... Agency concerns events of which an individual is the perpetrator, in the sense that the individual could, at any phase in a given sequence of conduct, have acted differently. Whatever happened would not have happened if that individual had not intervened* (1984, p9).

In other words, agency is the capability to make a difference, the art of changing the course of events; the capability, in summary, to turn one's own situation into something different, into something that would not have existed, or that would have been different, if the actor in question had not intervened.

What does this 'capability of doing things' depend upon? The problem with Giddens' definition is that too much emphasis is placed upon the individual. Agency expresses itself nearly always as a manifestation of several actors and explicitly not as something of which the 'individual is the perpetrator'. Even if it involves only one individual, the action expressing his or her agency should absolutely not be considered as an individualistic action. An individual only displays agency in interaction with other people or with other things.

Second, it is not clear from the quoted definition (which applies to Giddens' oeuvre, *tout court*) what it is an actor draws from to realize agency (hence there is little left but to represent it as a somewhat mythical individual attribute). What resources are mobilized to produce agency?

A more adequate description that addresses this problem, is presented by Long.

> *[A]gency attributes to the individual actor the capacity to process social experience and to devise ways of coping with life, even under the most extreme forms of coercion. Within the*

> *limits of information, uncertainty and the other constraints (e.g. physical, normative or politico-economic) that exist, social actors are 'knowledgeable' and 'capable'* (Long and Long, 1992, pp22–23).

Agency is made concrete in this definition, especially by pointing out what it relies on and builds upon: the capability to process and utilize the experiences gained thus far and also the capability to face existing and/or imminent difficulties (it should be noted explicitly that these difficulties are of a social nature – that is, concern the interrelations among actors and between actors and things). *En passant*, I want to mention that agency is discussed here as something that 'is attributed' to the individual actor, which implies that agency does not necessarily have to be rooted in or stem from the individual – even if it seems that way.

Third, when we speak about agency we should also mention its opposite ('non-agency'). Alongside the capability to make a difference, the opposite, incapability, also frequently occurs.[20] Without the latter, we cannot define the former.[21] Without non-agency as a conceptual and empirically manageable counterpart, agency becomes a non-concept.[22] A number of the issues raised here can be solved by involving the future-oriented nature of social action explicitly in the analysis. I will do this by way of Figure 8.4, which builds upon Figure 8.3.

Effective unfolding (from the initial situation A) along the first track (from A to C_1 and subsequently to C_2) is only possible if C_1 and subsequently C_2 can be effectively woven into the required relations. If we consider C_2 as a project in which strategic and future-oriented actions are united, C_2 can only be realized if coordinated and actually interwoven with other relevant projects.

> *Par définition, un projet … est une fiction, puisqu'au début il n'existe pas* (Latour, 1991, p155).

The essence of a project is that it does not yet exist, but that it has still to be realized. Let track 1 be the above-mentioned quality option of the beef farmer (the example returns once more). It will only be possible to realize this project if it interlocks with various other projects (first with X_1 and Y_1, subsequently with X_2 and Y_2). Groups of consumers will have to be interested in high-quality meat; they will also have to be able to recognize this. Butchers will have to be willing to distribute the meat as a distinctive product. Abattoirs are needed that are willing to slaughter an, initially, limited number of animals. And so on.

It might be possible to think of alternatives (for an empirical sketch describing production, processing, distribution and consumption of beef from nature reserves, see Kuit and Van der Meulen, 1997; Ventura and Milone, 2000). However, it remains to be seen whether these alternatives correspond with the way in which government implements and enforces hygiene regulations – which, in turn, could depend heavily on developments in the agroindustrial complex. More generally, it is highly conceivable that X (for example, the agroindustry) and Y (for example,

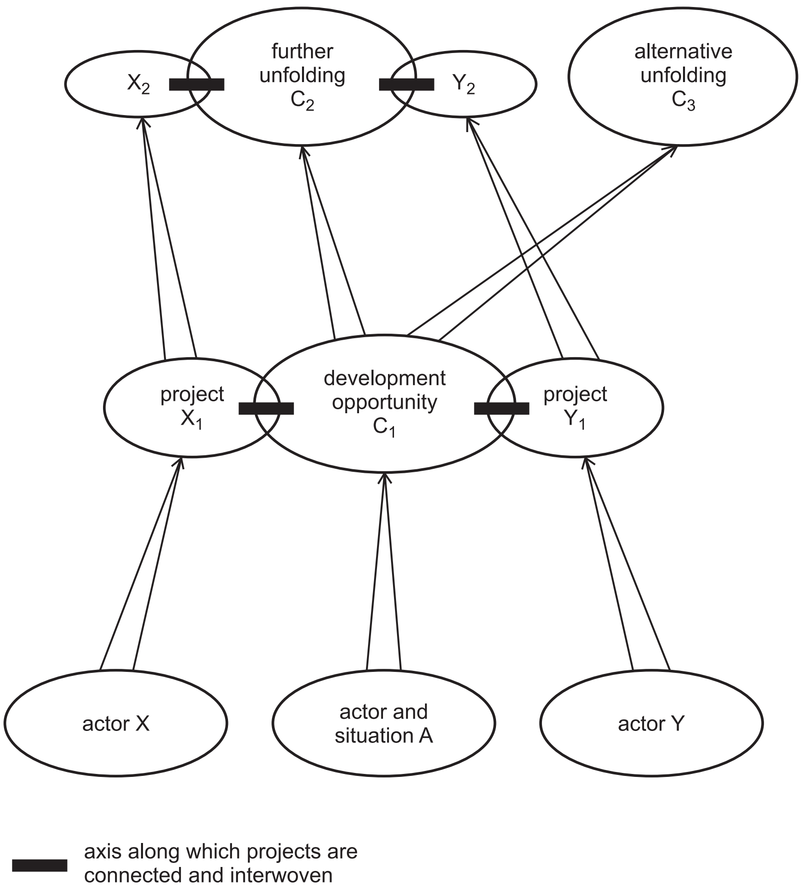

Figure 8.4 *The interaction between projects and the construction of networks*

government) establish their positions (X_1 and Y_1 and later X_2 and Y_2) to such an extent that actor A is left with only one trajectory (for a general view, see Burawoy, 1985; and with regard to agriculture, see Benvenuti, 1982, Benvenuti et al, 1989). Thus it becomes, for example, impossible to realize C_3 – unless actor A can actually develop mechanisms to distance himself from X_2 and Y_2.

'Realizing things' (of any nature) always happens through others, although to a varying degree – through other actors, through institutions, through artefacts etc. An 'actor-network' is needed: a set of precise (i.e. not accidental) relations with others, through and within which one's own 'project' can be realized. Through an 'actor-network' one's own project can be carried out, because through this network the project is connected to the projects and procedures of others. Such a network explicitly involves the 'social' (it includes other actors and institutions), the 'material' (it contains particular resources, artefacts and transactions) and the interaction between the two.

What then is agency? Agency is the capability to anticipate the necessary interaction and synergy of various projects – the capability to develop one's own project in such a way that the chance of actual synergy, of an 'interlocking of projects' (Long and Van der Ploeg, 1994, pp80–81), is as strong as possible. Hence, agency is also (and perhaps especially) the capability to interest and involve others in one's own project, the capability to encourage others to further unfold their projects in coordination with one's own. In other words, agency is the capability to create an actor-network. Only by doing so, is it possible to make the proverbial 'difference'.

Furthermore, agency is the capability to actually realize the initially *imagined* constellation (the set of 'interlocking projects' around C_1). The more and better anticipated, the more carriers of other relevant projects will become interested and involved, and the more and better the road to C_1 becomes effectuated. The more agency there is, the more capability there is to 'make a difference'. The less this applies (to whatever subject), the less agency there will be; hence, incapability emerges.

Initially, the network around C_1 is a virtual network (a 'prospective structure', according to Van Lente and Rip, 1998). The network is, as yet, only imagined. However, this does not make it less real, for it is above all real in its consequences.

Agency manifests itself through initially virtual networks; networks that are subsequently realized (or not). Therefore, agency should not be considered an individual quality. Whatever it is that I imagine and consider, does not in itself help me realize anything.

Agency is first of all dependent on the extent to which a virtual network can be imagined and, subsequently, can be constructed and extended. The individual actor emerges only in the second instance, in so far as he or she has the capability to contribute to the constitution, specification and realization of the intended set (the network) of 'interlocking projects'. Again, the role of the individual actor can only be understood in relation to the thoughts and actions of other actors – and definitely not in a strictly isolated, sheer individualistic sense.

What turns the commotion and goings-on of the human enterprise into agency? What is the ordering principle? What is the structuring moment? The answer is simple. The fluid and continuously changing concepts[23] with which groups of actors imagine the future – the *virtual* networks of intended future projects, whether or not attuned to each other – are structuring action. 'Commotion and goings-on' become agency in so far as they result in virtual networks that actually mobilize, inspire and cause realization. All action is future-oriented action (even though it appears to be different sometimes). Future-oriented action is structured via and by way of virtual networks – networks imply agency and at the same time define it (in a more concrete sense).

I claimed above that no structure exists beyond social practices (I should say socio-technical practices). Structure is immanent in social practices. That which structures is implicit in social practices as the way in which ordering occurs. How this process of ordering occurs is described here in a general sense: via the indicated virtual networks. Hence, structure is localized, agency is specified, which explains why the concept of structure is partly actor dependent and partly not; moreover, structure – that is, that which appears to be structuring – is the outcome of agency. At first this seems incomprehensible (and within the accepted Giddensian theories it cannot be but nonsensical), but it becomes plausible as soon as we integrate the time dimension and the importance of virtual networks into the analysis.

> *Networks, routinisation, and institutionalisation*
> *[A] network refers to a set of direct and indirect social relations, centred around given persons, which are instrumental to the achievements of the goals of these persons, and to the communication of their expectations, demands, needs and aspirations* (Anderson and Carlos, 1976, p28).

In this description, Anderson and Carlos stress, surprisingly, the orientation to the future – that is, the virtual nature of networks.

The concept of social networks was developed initially by anthropologists such as Radcliff-Brown and Mitchell (1969). Their direct intention was a better understanding of society in terms of 'fabric' and 'web of social life'. What keeps society together? What gives cohesion to, and connects, the commotion and goings-on?[24]

The social relations of which individuals are part can be analysed as a network (Boussevain, 1974, p25). A social network is more than a communicative structure, for many messages consist de facto of transactions – transactions that explicitly concern the material. In short, it concerns *socio-technical networks* (Wiskerke, 1997, p1). This applies a fortiori to the above-mentioned virtual networks.

In premodern constellations one would hardly, or even not at all, be aware of the extent to which the construction of the future occurs via virtual networks. The goals that those involved aim for, and more importantly 'the set of direct and indirect social relations' (the network) supporting the realization of the goals, are all largely routinized. Today's goals, and the social relations important for their realization, are the same as yesterday's. It is as if thinking is not needed. One can steer by the compass of the well-tried and proven. The required network does not seem to be virtual. It is the network that has always been there. 'That is just the way things are.' Having unshakeable faith that things would happen just like they did before, one could face the challenge of the future.

The most fascinating – and unusual, but no less adequate for that – critique of traditionalism and its routinization stems, surprisingly, not from science but from literature. This criticism is from Jean Auel (1980), who sketches the ins and outs of the 'clan of the cave bear'. The members of this clan act on the grounds of routine. The tried and true is the measure of (future-oriented) actions. Because the members of the clan increasingly, and despite themselves, gain *new* experiences, however, they have to remember more and more. Consequently, their heads become larger, the essential brain size intended for the required memory increases. This results in more difficult child births. The heads of the newborn babies, brimful of and hence swollen by collective memories, become too large. Therefore the clan becomes extinct. 'They didn't know it, but their days on earth were numbered, they were doomed to extinction' (Auel, 1980, p503).

In the modern period the creation of variation becomes an established, if not self-evident, phenomenon, resulting from the ubiquitous search for innovations and improvements. Of course, certain types of division of labour accompany this: not everybody can carry the risks inherent in innovation (see Hofstee, 1985). Similarly, (experiential) rules apply, structuring the process of innovation. Ironically, the smaller the proportion of what is potentially changeable, the higher the chance of success (Herrera, 1984).[25] Innovation is explicitly understood as a quest. This is typically expressed by the subjunctive, as explained by Van Kessel in a fascinating essay:

> *The subjunctive … is oriented towards the universe of possibilities, to everything that could exist in society* (Van Kessel, 1990, p92; see also Darré, 1985).

Talking and thinking about changes does not involve security but rather insecurity. Hope and desire constitute the most important guidelines; hence, the subjunctive mood. This grammar is in sharp contrast with the grammar of the previous, traditional period, characterized by the imperative, and especially with the grammar of the postmodern phase, in which expert systems use the indicative, which refers to the way reality merely *is*. This involves a highly objectified ('it is the case that …') and nomological language ('if this, then that'; see Koningsveld, 1987). Also closely related to the subjunctive, which is so typical of innovation in the modern period, is modesty: the success of an intended innovation depends on many elements that collectively compose the socio-technical network. Van den Berg (1989) gave his study about agriculture in the Peruvian highlands the meaningful title: *La tierra no da asi no mas*. The Earth does not give without difficulty – you cannot impose just anything upon her, let alone demand and expect just anything of nature and the living world (see also Salas, 1996). Looking back, this modesty (recognizable in many places)[26] is in striking contrast with the pretensions with which the process of innovation is positioned and legitimized in the postmodern period – but I will leave this aside for the moment.

Looking back, various other features can be recorded. It is remarkable that innovations almost always start at a small scale. This not only reduces the risks involved, but it also enables 'learning by doing' (Dosi, 1988). The initial small scale is partly related to the situation of utilizing mainly, if not exclusively, one's own resources (one's own land, own labour, own knowledge, own savings, own networks etc.). The latter feature, in turn, reinforces the multiformity of (potential) development routes, explored and realized through experimenting and innovating (Osti, 1991). After all, the specificity of the already present resources (irrespective of their nature) cannot but lead to multiple modes of unfolding (Jollivet, 1988).

In summary, the process of innovation as it occurs in agriculture under 'modern' conditions implies a clear balance. The development of new constellations ('new realities'), such as C_1 in Figure 8.4, assumes the creation of new (or more clearly specified) resources, and also of new combinations of resources and new (or at least partly new) networks. As a project, C_1 is (that is, from the position of the here and now, i.e. seen from A's position) a *virtual* reality. It is not there yet, but it is, presumably, possible to create it.

At the same time, this very *confidence* makes the project into much more than a merely virtual whole. It inspires actions in the here and now (at A in Figure 8.4) but also in the future and probably elsewhere too (see X_1 in Figure 8.4). It can and will also inform and inspire the actions of others, certainly if the project in question radiates sufficient authority and persuasion to create faith, to establish the necessary network (X_1-C_1-Y_1) in the future (C_1). Hence, there is an essential balance between, on the one hand, what is new, what is unknown, what is still to be realized and, on the other, the thus far constructed set of resources and what is knowable and controllable.

In other words, innovation is not the abrupt reorganization of what exists (for an applied analysis, see Van der Ploeg, 1993). Here, innovation represents the art of creating something new by making as much use as possible of the existing (see, for example, Brush et al, 1981); however, it needs mentioning that the 'existing' does change, precisely because it is fitted into a new, relevant whole. *Voilà*, the paradox of the innovation process: the less virtual the networks, the higher the chance of creating them and, hence, new 'realities' (such as C_1). The tension between possibility and reality is essential for the innovation process, but a careful 'monitoring' of the tension is equally essential. Just like an elastic band, it cannot be allowed to break.

At this very point, one of the central differences between 'modern' and 'post-modern' constellations emerges (between Figure 8.1b and Figure 8.1c). The definition of macroprojects (or 'megaprojects', following Scott's terms) by, and from the position of, one or more expert systems is crucial (see Figure 8.5). Such macroprojects are pre-eminently virtual. They are in principle disconnected from the identities, resources, projects and networks that apply here and now (at moment X). Here the balance between what is virtual and what is real, so typical of the modern constellation, is largely if not completely absent. Hence the intended innovation can only take place as a comprehensive reorganization.

In this book, I will discuss such a macroproject[27] at length: the reorganization of agriculture according to the models developed in the expert system in and around agriculture. I use the metaphor of the *virtual farmer* for this. The 'virtual farmer' is an image developed in the expert system. It concerns the farmer (or grower) as s/he should be and should function according to the assumptions that are axiomatic within this expert system. The same metaphor also refers to agriculture as a whole – at least, as it should be – and to farms as they should be.

The virtual farmer refers to the 'one order world', to the only conceivable, rational model towards which the actions of a wide range of actors, of government, of banks, of agroindustries, of farm men, of farm women, of advisory services and research centres and so on, need to be directed.

Hence, the virtual farmer also defines a network, a virtual network. However, the latter network does not contain a balance between reality and possibility, it is completely virtual. It does not consist of the unfolding of the potentials contained in the current reality. On the contrary, a rupture emerges: the development opportunities are replaced by the new, virtual macroproject. This macroproject directs and sanctions the actions of various actors in and around the expert system in an almost coercive manner (see Figure 8.5), in such a way that, on the whole, the intended reorganization materializes. Hence, the macroproject implies *trust*, the essential cement assumed in a constellation such as that sketched in Figure 8.5. A virtual network can only function by the grace of trust – that is, by the grace of faith in the prospect suggested by the expert system. Also, it can only function in so far as various unintended consequences of the macroproject can be controlled and/or externalized.

The realization of a macroproject can only happen via and as a comprehensive reorganization. This implies that variation and selection cannot happen via the multiple unfolding of various realities. Here selection is no longer part of the development process: selection becomes a one-off and occurs *ex ante*.

Alongside macroprojects, other alternatives are implicitly or explicitly interpreted as inferior; and as undesirable, because the realization of other, competing alternatives cannot but be an intrusion on the intended comprehensive reorganization, reducing the efficiency of the operation as a whole. Similarly, a partial realization of other opportunities refers to an insufficient degree of trust; the virtual

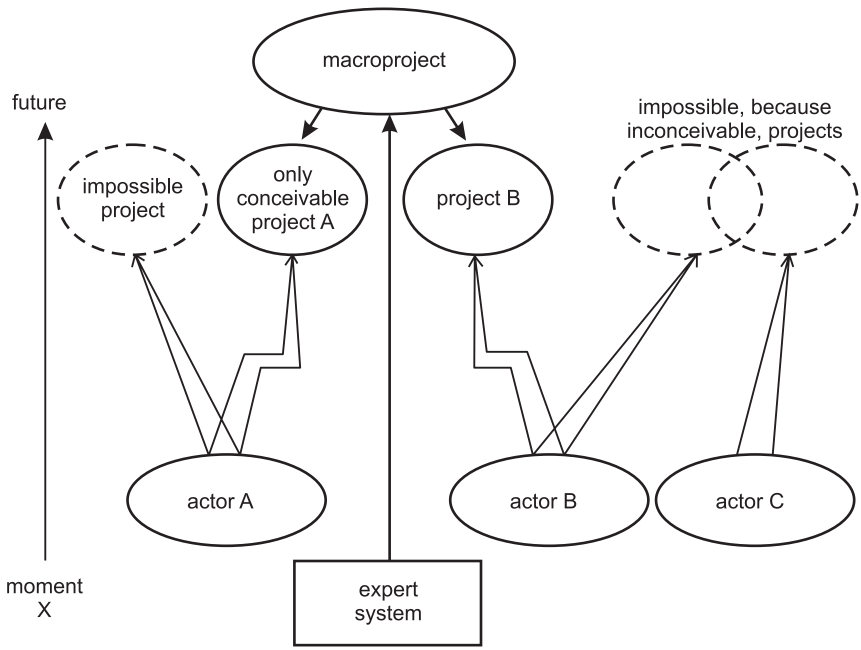

Figure 8.5 *The directive role of macroprojects*

network would be incomplete. In summary, variation is thus significantly reduced from the beginning.

En passant, this points to the essential differences in scale. The intricate types of development, characteristic of the modern constellation, will be relatively small in scale because of the reasons briefly touched upon above, especially in the initial phase of conceiving, experimenting and innovating.

In a postmodern constellation, on the other hand, the realization of macroprojects implies almost by definition a large scale. Not for nothing, system innovation has become a catchword. Various other implications arise from this difference in scale. I refer to two effects here. First, transformation costs will be very much higher, not only because of differences in scale but also because of the generally high degree of disconnection from the existing situation. The macroproject does not build upon the resources, networks, identities and opportunities inherent in the existing situation (X) as described in Figure 8.5, but represents a rupture.

Second, a 'democratic issue' of a completely new order emerges. Realization of the macroproject leaves little opportunity for discussion and learning, whereas multiple unfolding provides more room for the insights and choices of the different actors themselves. While existing and virtual networks coincide within traditional constellations (because the future can only be imagined as repetition of the given) and while modern constellations consist of an undeniable tension, of a carefully managed balance between both types of networks, in postmodern constellations one finds the *other* extreme. Just as, in general terms, the future dominates the present, in a more specific sense, virtual networks come to dominate the current networks and practices. In agriculture, this becomes strikingly clear in the fact that those who define and materialize the future (the macroproject) are completely different actors than those who constitute the current relevant networks in and around agriculture. Alongside these complications, there is another, central, paradox. Conceptualizing innovation is no longer difficult. The expert systems are well up to this job. On the other hand, realization of the imagined innovations (the intended macroprojects) becomes one of the main, if not the central, problems. Here capability and incapability emerge again as two, closely related, themes.

Finally, an observation about the often extreme degree of 'institutional clustering' arising in postmodern constellations in and around these virtual networks. Innovation revolves, in essence, around the recognition, realization and utilization of new possibilities. New possibilities (that currently do not exist but that could exist in future) are the pre-eminent resources in the postmodern constellation (one could say, with some irony, that resources too have become highly virtual). However, by way of large macroprojects, such as those developed by different expert systems, this future has already become highly parcelled out by the state. The future is divided into fields that are considered to be conceivable, realizable and legitimate and into other fields that are considered to be inconceivable, unrealizable and illegitimate.

Hence, in the postmodern constellation, the virtual network is highly institutionalized. With respect to various future projects (irrespective of their nature) particular government organizations function as gatekeepers. A constantly expanding set of rules and procedures is developed to this end. The realization of different future projects (surfacing in civil society) is only possible in so far as they correspond with these procedures, in so far as they provide support for the gatekeeper, or, more generally, in so far as they are in line with prevailing macroprojects.

From this point of view, the state is, above all, a complex machine that seeks to prevent its parts from entering (for whatever reason) into hasty arrangements: the meetings, the endless consultations, the mechanism of initialling (all divisions and departments involved have to agree), the mechanism of co-funding, the procedures and calendars all function to eliminate every possible deviation from the prevailing macroproject (and, at the same time, to orient all possible resources and networks towards the macroproject in question).

The effects are threefold. First, the so-called transaction costs (the costs that have to be made to make something happen, to get something done) increase often to extreme levels. Second, the rules, procedures and gatekeeper functions often gain an independence that reaches far beyond the initial macroproject. It is possible for a macroproject to have long lost its meaning and importance, while the rules and procedures retain their own power. This can lead to grotesque events: important innovations remain unnoticed or are hindered. During the past ten years, I have witnessed extreme examples of this. Innovations that emerge outside of this expert system are regarded as suspect – as undesired competition, even if only in a symbolic sense. Hence, numerous potentially valuable innovations remain marginalized, restricted to the proverbial proportions of 'hidden novelties' (see Van Lente and Rip, 1998).

I came across a different expression of the same tension through the so-called 'commissions of wise men' of which I was part several times (probably by mistake). Such commissions are generally launched in The Netherlands when implementation of the prevailing regulations leads to almost insoluble problems and conflicts between those involved. To a researcher, these commissions constitute an exceptional research method as well as an extraordinary learning experience. One of the things that I have learned from them is that the solution, the way out of thorny problems (irrespective of whether they are concerned with the ammonia question in south-east Friesland, the national ecological network and the Gaasterland uprising,* or unemployment in the north of the country),[28] is often very simple in theory (because it assumes at the most a flexible interpretation of rules and above all a clear focus on objectives). The complication lies in sidestepping the prevailing procedures, arrangements and (bureaucratic) identities in ways that do not set a precedent or mean that the civil servants involved lose face.

This takes me to a third complication. This is the 'democratic deficit' brought about by, and effectuated in, this procedure. The *trias politica* – the separation of

* *Translator's note*: The realization of the national ecological network was initially imagined as a massive expropriation of farm land in order for it to be converted into a nature reserve. In Gaasterland, the entire population (including the non-agricultural population) protested against and effectively blocked this approach.

powers, at one time the basis of our polity – becomes increasingly lost as a result of the institutional clustering. Increasingly one and the same group of highly specialized and highly gifted civil servants are responsible for (i) developing the rules that regulate the workings within a particular socio-material domain (for example ammonia emission and deposition), (ii) providing for the 'right interpretation' of these rules and (iii) deciding when the rules are violated, or not. In short, even though the term 'postmodern' constellation seems to suggest a more or less definite, or at least superior, mode of social ordering, as yet things do not function at all smoothly.

The coordination of projects

With a view to the empirical analysis of the differences discussed here between multiple processes of unfolding, on the one hand, and macroprojects, on the other, we need an adjusted vocabulary, a set of interrelated words and concepts, which, on the one hand, does justice to the outcome of events while, on the other hand, being fundamentally non-determinist (Knorr-Cetina, 1996).

One of the concepts of great importance here is agenda-setting (Rhodes and Marsh, 1992; Baumgartner and Jone, 1993; Kingdon, 1995; Just, 1998). That is, defining the situation, specifying problems, indicating directions for solutions, and hence identifying the resources that have to be mobilized in order to implement the intended solutions.

Agenda-setting is not a neutral activity. Crucial issues are who is to join in the discussions, and who will be excluded.[29] Joining in the discussions provides the opportunity to influence the agenda: it gives authority and, conversely, only authoritative persons are invited to join in the discussions. As such, an agenda represents authority. An institutionalized agenda influences the thinking and acting of others – even when there are no face-to-face relationships; in that case we can only speak of 'control from a distance'.

What is authority? Authority, you could say, represents insight into, and overview of, the relevant whole – that is, knowledgeability and capability. For this reason, and also because of the related capability to subsequently arrange events according to this insight and overview, we can define authority as a type of agency. It is not, however, an arbitrary type of agency but rather one that is generally recognized. Again, this makes clear that agency is not an individual attribute. It emerges in and is brought about by networks.

Control over and mobilization of resources deserve – as do agenda-setting, authority and networks – a prominent place in the vocabulary with which structuring or ordering of social practices can be understood in a non-determinist sense. However, it is essential that resources are not taken at face value.

Speaking straightforwardly, a certain area of land, a number of cows, a shed with adjacent buildings, a certain number of labourers (or whatever) do not represent resources, either intrinsically or collectively. Material and/or social elements become resources only in the case of a more or less explicit model, in which they are congruently forged together into a working and sufficiently promising whole, into a solution, a vision, an expectation.

Such a vision or solution ('how to achieve goals', following Anderson and Carlos, 1976) also represents authority in the above-mentioned sense. It represents authority if it (i) concerns the relevant whole, (ii) puts something into perspective and (iii) is recognized as such by a sufficient number of actors.

Defining boundaries is an element that needs separate attention. It is partly implicit in the definition of problems that follows from agenda-setting. Determining the boundaries is also closely linked to the question who does and who does not join in the discussion about the agenda. The same applies to the other elements. Take authority, for instance; authority is not limitless. Authority always applies vis-à-vis a more or less defined territory; outside of which apply the remarks: 'What's it to you?', 'What do you know?' Boundaries are crucial. They are also constantly subject to dispute, negotiation and renegotiation. Boundaries mark inclusion and exclusion. But again, this repeatedly concerns exclusion and/or inclusion vis-à-vis something. This applies perhaps pre-eminently to the presented solution, which must be defined as superior in comparison to other trajectories, by way of a clearly defined boundary.

Agenda-setting, authority, resources, solutions, boundaries – these are all concepts that mutually define each another. Without the other terms, each concept on its own becomes an isolated and therefore meaningless notion. Collectively, these concepts refer to an actor-network (or a socio-technical network). Within this network, agendas, authority, solutions and so on follow naturally from one another. It is the essence of a network to produce a high degree of congruence.

A typical feature of the period of modernization is the emergence of complex constellations characterized by a multitude of networks that operate alongside one another, but which also partly overlap and partly compete with one another. In other words, there are *multiple structures*, and therefore variation and selection; hence, the ordering of a highly heterogeneous world.

Why? I will confine myself to one or two observations. Compared to the traditional world, agenda-*setting* became increasingly desacralized in the modern world. Priests, elders and nobles lost their power and control. People themselves were increasingly looking for solutions and answers. New forms of authority were acquired in the process and, again, became institutionalized.

Another example concerns the value of what is tried and true (the Jean Auel formula). Confronted with the decreasing importance of local authority and with the emergence of new, at first seemingly imperative parameters such as markets and technology, many farmers redefined their solutions in their own, often original, ways, hence giving rise to a whole gamut of farming styles. Of necessity, they crossed the boundaries of the tested and true and developed various, contrasting, sometimes complementary, sometimes competitive solutions, each of which represented a search.

The preconditions for such a development are also clear, at least in retrospect. Again, I confine myself to a few considerations. The first concerns the degree of institutional clustering. Or rather, its absence. Far-reaching institutional clustering can, as I argued above, nip many, if not all, innovations in the bud. In this context, it is telling that calls for 'protected spaces' are heard (Kemp et al, 1997; Kemp et al, 1998; Van Lente and Rip, 1998) in the very situations that are characterized by a high degree of institutional clustering. A second essential precondition concerns the necessary self-confidence. A third concerns the required design capacity, the art of creating new solutions and new development opportunities.

Actors, Projects, Co-production, Convergence and Distantiation

In the beautifully written introduction to *Organizing Modernity*, John Law describes projects as 'self-reflexive strategies for patterning the network of the social' (1994, p20), a description which captures the meanings of agency, virtual networks and their interrelations. At the same time, Law describes these strategies as modes of ordering, as the mechanisms that shape social life. This underlines that these modes of ordering do indeed work via the future, precisely because they are the expression of the reflexive strategies that constitute networks.

No direct one-to-one relation can be assumed between a mode of ordering and the practices that emerge from it.[30] The decisive element is the interaction between various modes of ordering.[31]

As indicated previously (in part as a result of Figure 8.4), the presence, interaction, synergy and tensions between various, sometimes even conflicting, modes of ordering must always be anticipated in the construction of a network. The outcome of this process is, in principle, indefinable. Strategies and projects will be adjusted – that is, unfolded in a particular way – to enable interlocking of and/or distantiation from other projects, strategies and modes of ordering. Considered thus, a network ('for patterning the social') is, above all, a particular set of modes of ordering linked together or defined vis-à-vis one another.[32]

In the process of constituting and developing such networks as a set of interrelated projects, interfaces are crucial. This concept, largely developed by my colleague Long, refers in essence to discontinuities, to issues and social relations that do not necessarily follow on from one another (Long, 1989; Long and Long, 1992).

The idea grew from another concept: linkages. A different research group (from Leiden University) developed this concept to explain how various issues and relations are constantly forged together by linkages, originating from their (supposedly) underlying structural patterns. The Wageningen reaction to this, most imaginatively expressed by Long, was that it was not so much the unproblematic linkages that should be the focus of attention, but rather the incapability to combine various issues and relations (i.e. the problematic linkages).

Thus, interface analysis was born – that is, the study of both discontinuities and the, above all, unpredictable and often difficult to grasp ways in which translations sometimes emerge at the level of interface – translations that, in turn, produce a highly ordering effect, even though it is not chosen by anybody as such.

> *Interface studies are essentially concerned with the analysis of discontinuities in social life. Such discontinuities are characterised by discrepancies in values, interests, knowledge and power. Interfaces typically occur at points where different, and often conflicting, 'life-worlds' or social fields intersect. More concretely, they characterise social situations … wherein the interactions between actors become oriented around the problem of devising ways of 'bridging', accommodating to, or struggling against each others' different social and cognitive worlds* (Long, 1989, p232).

The development of a project implies risks, which are largely related to the question of whether the required connections with other projects can be established. Considerable risks exist on and around the interfaces. Heavy investments are often required in the creation of concrete agreements. The withdrawal of one actor can imply a major disappointment. Realization of possibilities that have thus far not been taken advantage of is risky, for the individual actors involved in the construction of a new network, and for all of those involved as a whole.

Risks are perceived in various ways. If the realization of a certain project presupposes a considerable input of external capital – that is, the association with an external financier – this introduces a perspective in which the relation between opportunities and risks are decisively different from when this does not apply. External funding implies a particular way of valuing invested capital – that is, as an increase in the value of invested capital. This entails particular criteria: it forces the actors involved to develop their project in a particular way – that is, to extend certain possibilities, to curtail or exclude other possibilities, to enter into certain coalitions, to rule out others. Such 'coercion' will apply less if one can use one's own resources and if other forms of valuation can be chosen.

Financial capital[33] wields a highly conservative influence: it 'forces' the development and utilization of new possibilities into the mainstream of established projects and their related interests and visions. It corkscrews new plans towards dominant constellations and towards their associated certainties. These constellations seem to offer *trust*, the (supposed) certainty that there is no, or a lesser degree of, risk. Related interests are reproduced via the chain of risk avoidance, the search for certainty and dominant visions. Capital, in the Marxist sense, represents power and dominance, but not for intrinsic reasons. Capital retains its dominance because it is repeatedly used as a guiding compass in the process of project development.

There are, of course, other ways to develop and realize a project:

1. by using resources that do not need to be used as capital in the narrow sense of financial capital;
2. by using other calculi, with a broader range of values;
3. by structuring the development process differently (for example, step by step as opposed to all at once).

Agency is crucial in the development and realization of projects. In this context, I understand agency to be the capability to create the required interrelations with other projects. In other words, the capability to recognize, to utilize, to bridge or to reconceptualize discontinuities as essential demarcations. Insight into the interaction between intended plans, the interaction between presupposed positions, actions, reactions, outcomes, benefits, costs and their allocation is decisive in this.

Therefore, agency is the capability to create *virtual congruence*:[34] congruence that does not yet exist (or is not yet necessary), but which is decisive for the future of the projects under discussion. To create future congruence, coordination in the here and now becomes decisive: the required congruence is achieved by way of coordinating various development projects vis-à-vis each other. Failure to do so results in incongruence. Fragility is therefore a term that should be part of any analysis of social developments, because the effective construction of congruence and coherence is probably the exception in real life. In view of the many possible discontinuities, risks and incapabilities, failure seems to be more likely than success. This applies more strongly when it concerns innovations and the more so when it concerns deviations from the institutionalized patterns and regularities. The search for and extension of such 'deviations', however necessary when established patterns go wrong, is and remains particularly fragile.

An Example

In the autumn of 1998 the *Friese Ecologische Zuivelfabriek* (FEZ, Frisian Organic Dairy Products) was opened in Drachten. However, the real, the essential, innovation is not the building and inauguration of this factory, but the preceding rearrangement of projects vis-à-vis one another. Numerous projects were at issue here: those of the many organic dairy farmers (about 80 in Friesland at the time) who at the time had to have their milk processed beyond the provincial borders; furthermore there was the, shall we say, potential project of an unknown number of dairy farmers considering a changeover to organic production, but confronted by a series of questions. These questions all related to the future actions of others. They raised many uncertainties: will consumer demand grow sufficiently to support the higher supply levels and maintain higher prices? Will the cost increases related to producing organically exceed the benefits? Will the profits of the organic circuit become increasingly extracted by those controlling large-scale processing (that is, the owners of the new organic dairy factory)? Is it possible, if the intended project (the changeover to organic dairy production) appears set to fail, to fall back on the existing patterns (specifically: will it be possible to rejoin Friesland Coberco Dairy Foods, the largest and, by now, sole processor of milk in the north of the country?).

The initiators (who intended to build the FEZ) also had an almost infinite series of questions, which again were related to the future actions of others. Will sufficient dairy farmers want to change over and supply the new plant? If not, there will be underproduction and losses.

If the new project to establish processing and marketing units is successful, will the big brothers (the established dairy companies) subsequently decide to invest in this new area and attempt to outcompete the FEZ? Will consumers accept the scale increase of production, processing and marketing? And is it possible to realize a reduction in the consumer price through this scale increase (and the subsequent cut in, for example, logistical costs), without having to lower the farm gate price? Alongside consumers, who buy organic products for reasons of principle, will new groups decide to purchase because of the lower price (although still higher than the price of non-organic products)? To what extent will supermarket chains cooperate? Will financiers (banks) want to cooperate in the realization of the intended project? And to what extent can new government projects, such as green funding, be used in order to win the financiers over and/or to present better conditions?

It is clear that – even though we have only discussed some of the actors involved – their projects, and the many questions and uncertainties surrounding those projects, cover an almost infinite sea of possibilities. If each actor has at their disposal X alternatives of future action and there are N actors in question, X is raised to the nth power. In the case of eight actors (organic dairy farmers, farmers considering a changeover, the initiators of the FEZ, the conventional dairy companies, consumers, banks, supermarket chains, government) who each have, say, five alternatives for action at their disposal, there are almost 400,000 (390,625 to be exact) possible final constellations, the majority of which will be characterized by a sometimes high degree of incongruity.

Only in a limited number of cases will there be congruence, a 'working whole' (Roep, 2000) functioning properly and, indeed, generating the expected results and distributing them in such a way that there will be continuity.

To be able to operate in this sea of uncertainty (that is, to be able to actually realize innovations), it is essential for all relevant actors to choose or develop their alternatives for action in such a way (to have their projects evolve in such a way) that real interweaving and mutual reinforcement emerges. Projects should be integrated into the working whole; a working whole that does not yet exist, but which (still) needs to be realized. In other words, it concerns an (increasingly concrete) expectation that will structure the doings of the actors involved (as expressed by the slightly abject, but still frequently used phrase that 'they have to be of one mind').

In the creation of this expectation (this interpretation of a new working whole), an essential role is played by agenda-setting, integration, boundary definition (who will be involved?, in which ways?, how to keep negative and disintegrating forces at a distance?) and scale (what level of cooperation and how many participants are needed to define the 'working whole'?). The more convincing answers, solutions and prospects are generated with respect to integration, definition, and scale the more convincing the presented course through the sea of uncertainty will become (precisely because the uncertainties and their associated risks become eliminated step by step).

In fact, the thus presented degree of complexity returns at least twice. For even though it is possible to conciliate a working whole, it will actually have to be constructed subsequently. The seemingly real possibility will have to be realized. This is only possible if the participants effectively devote themselves to its realization. If they do not – if in the interim they withdraw or they adjust their projects in a non-congruent way – it can still go completely wrong. Thus, the trouble experienced by other participants will appear in vain: it will reveal itself as a cost with no return. Hence, fragility needs to be considered.

Furthermore, a solution (whichever one) will have to contain a sufficient degree of acceptability: there will have to be an acceptable balance between advantages and disadvantages, between benefits and costs. If it appears that free riders can rake in an unequal share of the benefits without sharing the costs of the whole, this may provoke extensive desertion. The same will occur if some partners have to carry a more than equal share of the costs.

The uncertainties in question are largely related to the expectations of the actors involved with regard to the future actions of other, similarly involved, actors. What will the others do? And to what extent will I be able to influence their projects? Or rather, to what extent can the developments of my project and that of the others be integrated so as to create co-evolution? How can fragility be reduced? How can the required acceptability be achieved?

These are weighty questions, especially if one realises that neither hierarchy nor the autonomous development of market relations[35] provide an obvious answer and/or a smoothly functioning mechanism for the construction of such an answer.

Why and how was co-evolution constructed in this particular case? I will only mention a few elements here. A first important element was the increasing pressure from supermarket chains on the large dairy companies to offer a range of organic products alongside their conventional ranges. Given the hesitation of these dairy companies to independently start a separate line for processing of organic milk, a coalition between the initiators of the FEZ and the large dairies became increasingly obvious. The latter eventually participated in 33 per cent of the financing of the FEZ; more importantly, they also declared that their suppliers were allowed to change over to the FEZ without having to pay withdrawal fines; furthermore, the suppliers would have the right to rejoin the companies in question within three years if FEZ's results were disappointing.

This clearly indicates a package deal: participation in the FEZ and hence being able to satisfy the desires of the supermarket chains became possible by offering good conditions to the potential suppliers. Thus, various projects became interwoven; they were combined into the indispensable connections upon which the new working whole had to be based. As a result of this package deal, which was definitely not undisputed, a number of other positive effects occurred relating to distribution and its costs. If lorries of the large companies stop at the FEZ, supermarkets could be supplied with a wide range (including organic products) from one lorry-load.

In early 1999 I had a long conversation with Henk Brouwer, initiator and current director of the FEZ. Looking back he says;

> *Yes, you do indeed set out with grave uncertainties, and you want to move towards more certainty. But of course you never achieve this… If I look back, it was mainly faith that grew in the start-up phase. Faith on both sides and also faith in one's own abilities, to the extent that you dare to take risks. You need faith, commitment of all those who will become involved in such a chain, of farmers, financiers, retailers, the whole lot. This faith will in turn give you the feedback that you're on the right track.*

Here I want to bring forward a number of elements that played an important role in the creation of this faith (and therefore in the construction of the FEZ as a new socio-technical network). I do this especially because these elements are in sharp contrast with the way in which expert systems usually operate and also because those same elements sometimes represent a somersault through past, present and future.

A first element concerns the *goals*. While expert systems usually arrive at a clear indication of objectives, to subsequently implement these via standard planning techniques (which create *en passant* the required prescriptiveness and verifiability; cf. Christis, 1985), a completely *different* approach applied to the creation of the FEZ:

> *You have to know which way you want to go, you'll have to be very clear about it, but otherwise your more concrete goal is something that emerges slowly as something that you work towards. Most important is to define the margins, to drive pickets into the ground. Those margins or boundaries are V-shaped as it were, they take you closer to where you want to be … Yes, of course it's true that you adjust your objectives along the way. I wanted much more at first, and other things too.*

In other words, the goal around which the necessary set of partners (the *virtual network*) groups itself, is not well defined. In fact, it is precisely the other way round: an at first loosely organized network is gradually working towards a set of shared objectives. Partners will drop out, new partners will join. Meanwhile, the possible goals become more and more sharply defined, hence creating faith on both sides.

Network and strategy consolidate each other to the same extent. Neither one is a function of the other. Henk Brouwer is very outspoken about this:

> *In the beginning you're swimming against the tide. I have had some problems addressed – for example, where roughly the break-even point would be. It gives you some idea, and then you can again determine where the margins are, where the pickets have to go; and thus the end goal gradually takes more shape [agenda-setting and particularly agenda-building appear as key factors here]. No, the planning approach with one well-defined goal from the start, from which you have to reason backwards – it doesn't work like that. Yes, that's the way the large organizations*

> *deal with things, but not surprisingly that's how they kill everything off. The Investment and Development Company for the Northern Netherlands [*Noordelijke Ontwikkelings Maatschappij*] wanted me to do that, but it was impossible of course. That's how they set up a dictatorship, they dictate things, they issue a diktat, but things work the other way round.*

A second important element was, so I understand from Henk Brouwer's story, the introduction of clear *rules of the game* on the basis of which the required network (however virtual at first!) could be demarcated and consolidated:

> *Farmers, processors, and the trade, and the others too, they all had to benefit from it.*

Hence, the foundation was laid for the actual interlocking of various projects, which occurred much later.

But more rules were developed:

> *Sooner or later you'll have to make it clear that it will continue, with or without the other.*

Here emerges what I pointed at previously: authority. And related to this: the moment at which involvement (of the other partners) becomes a choice, whether or not to actively contribute and devote themselves to the cause.[36]

Furthermore, there is a third element, the combination of *autonomy* and *fallback position*. The most important resources were to a large extent controlled by the initiators. Here I refer not so much to financial resources (which partly evolved from the sale of a considerable share of the quotas of their former dairy farms), but above all to immaterial resources, such as the capability to (in all likelihood) actually manage the required socio-technical network (to actually supply retailers with a high-quality and organic product, to actually have retailers commit themselves, to actually have a number of producers supply organic milk etc.).

Agency, not in an abstract but rather in a concrete sense, reveals itself here as resource par excellence. In obtaining this agency, the aforementioned start-up phase (in which a network emerged, expectations were adjusted vis-à-vis one another, faith emerged) was a *sine qua non*. Without wanting to go into detail, the availability of a fallback position ('if it had gone wrong, it wouldn't have been the end of the world') was important in the creation of this indispensable precondition.

An organic dairy factory has now been established in Drachten, despite being initially regarded by various expert systems (the 'Eindhoven' office of the Rabobank,[37] the large dairy companies[38] and the Ministry of Agriculture)[39] as unthinkable and/or unfeasible. The creation of this factory is exceptional in that it illustrates the realization of agency in a context characterized by and also controlled by expert systems that increasingly rule out such agency.

It goes without saying that all this is closely related to the question about the interrelations between various ordering principles, and to questions about who and what will create the future, which conditions will have to be met, and what its legitimacy will be.

Agriculture as Empirical Object

Agriculture as a particular empirical phenomenon presents complications, but also a certain advantage. The advantage can be described easily. The search for and creation of congruence and consistency within projects (between the natural and the social) as well as between projects, the subsequent complexity of the coordination issue, and the sometimes inclusive, at other times radical, nature of the variation and selection processes make their presence felt more in agriculture than in other areas. Why? In agriculture, there is always and everywhere an enormous number of actors. There are now about 110,000 farms in The Netherlands, involving more than 300,000 workers. Furthermore, there is an immense agribusiness: a set of enterprises supplying commodities and services to the primary sector. A further 250,000 workers are involved in this.

In contrast to various other sectors, this complex and variegated whole, this multitude of projects, cannot and does not allow itself to be managed like a command economy. Coordination is essential, particularly in and around agriculture. In addition, present, past and future fall continuously on top of each other, sometimes in the most bizarre ways. This makes contemporary agriculture such a fertile, yet difficult, empirical territory for the issues under scrutiny here.

Two issues should be clarified from the outset. They concern the relation between the words and the things, and between things.

There once was a time when it was felt that The Netherlands were 20 years behind the rest of the world – Germany acted as the most direct point of reference. Similarly, agriculture and the countryside were seen as being 20 years behind the rest of society, i.e. the city.[40] All in all, this does not do agriculture and the countryside much good. It is hard to imagine them without the stigmas of slowness and tradition, of reluctance and resistance to adopt that which has been widely accepted elsewhere for some time. Incidents, discussions, images and events that seem to support such an interpretation are not difficult to find.

What needs to be stated clearly and resolutely is that the agricultural sector is often more modern, progressive, dynamic and innovative than the rest of society. Not 40 years behind but in some ways 10, sometimes 30 years ahead. However, this applies (let me dampen the fun at once) not only in a positive sense but also in a negative one.

In the conventional view of agriculture, the countryside is seen as intrinsically traditional and conservative. While the rest of society had thrown off the shackles of the past, the modernization project only began to become defined in agriculture in the late 1950s. Backwardness rules, certainly if we realize that at the end of the 20th century things have still not been put right.

In this conventional image, the relation between the words and the things is completely amiss, persistently amiss. For, even though these are established self-evident habits, or an institutionalized view, it has to be stated that the relationship between the notions employed and the practices grasped and interpreted with these notions suffers on all sides.

Of course, there is tradition in the rich and complex agricultural history of The Netherlands. However, there is no absolute traditionalism, in the sense of conservatism and stagnation. This has been demonstrated in the diligent work of agricultural sociologists and historians. The seeds of progress slumbered in the bowels of tradition.

Certainly in the 19th and 20th centuries, a comprehensive process of modernization took place, spurred on and driven by the peasants of the time. Tradition and progress, conservatism and progressiveness do not constitute opposites. As I will stress, each needs the other. The balance between the two is essential (Terron, 1984).

The great modernization project became defined at the end of the 1950s. However, the principal issue is that, again, the word was wrong from the beginning. It is not true that agriculture only started to modernize from that moment onward. It had been modernizing for a long time. Looking back, one cannot but say that this so-called modernization project was definitely not what was expected and suggested at the time (nor later): to finish once and for all with tradition, to finish once and for all with the rural as consistently backward.

The agricultural modernization project of 1950–1990 was one of the first great megaprojects realized in The Netherlands.[41] It was not an adjustment of a past that was moving too slowly, it was a universal operation in which the future was made to dominate the past and the present. All in all, the so-called modernization project in agriculture was (and is) an 'undercover megaproject'. It was not the beginning of modernization in agriculture, it was about the forced implementation of another modernization path than the path or trajectory followed up to then. However, the particularities of this modernization path remained undiscussed, for it seemed to be about modernization *tout court*.

The gradually manifesting chaos of the undercover megaproject should be thought through and included in the planning and assessment of the megaprojects that are now (40 years later) being defined in society at large. There is a case for the thesis that expert systems and macroprojects are almost inevitable in contemporary society – at least with regard to certain issues.[42] What is fascinating about agricultural modernization as a macroproject, however, is that it was unnecessary, certainly from a comparative perspective. We would have had a different kind of agriculture – probably of a better kind, maybe of a worse kind. However, it is impossible to maintain that agriculture and the countryside would have vanished without the great modernization project. This knowledge prompts a critical examination of the ways in which expert systems operate and intervene in the organization of time, space and social practices.

So much for the relationship between the words and the things, the social constellations and terms with which we interpret and understand them. As I stated previously, the social sciences try to understand every constellation using the vocabulary and the regularities of the previous constellation. This applies a fortiori to agriculture. As if by natural law, the things and the essentials of the periods in question are invariably interpreted and understood wrongly.

The next issue is the relationships between things. What is fascinating, but also confusing, about the world of agriculture is that there are no separations between periods and phases. Even though there are noticeable shifts in emphasis, overlap and mutual influence predominate rather than clear boundaries. In the traditional phase or constellation (see Figure 8.1a) agriculture was already modernizing rapidly. And during the decades in which the process of modernizing had become dominant (as represented in Figure 8.1b) a megaproject, confusingly named 'modernization project' was developed and implemented. This was in fact an expression of the 'postmodern' operation of expert systems *avant la lettre* (see Figure 8.1c). More accurately, the moment when the past finally seemed to lose its straitjacket, two new, unequal but interconnected, developments emerged.

On the one hand, modernity, which had already been hidden in the bowels of traditionalism, made its entry. Building upon experiences, practices and resources, which had all been handed down through history, multiple developments were initiated resulting in a variegated morphology, in a wide range of farming styles, each one equipped with a particular future project, an attempt to develop its own practice (that is, its own farm and set of relations into which it is woven) corresponding most closely to its own wishes, insights, interests, capabilities and limitations. Even though the term would be used only much later in the social sciences, one could say that agency increasingly flourished from this moment onwards. More or less at the same time, a countermovement was defined, for an expert system was created through which farm development was represented as a uniform process.

It follows clearly from the previous explanation that the phases I described above cannot be regarded as consecutive, let alone as well-defined periods. They are ordering principles, ways of relating past, present and future in and through social practices. Analytically, one can attempt to define certain basic patterns vis-à-vis each other; empirically, however, one will always encounter different and mutually conflicting principles, sometimes dominated by the one, sometimes by the other.

Recent agrarian history is usually narrated in terms of necessity and inevitability. The development of agriculture is, to coin a phrase, structurally determined. Agricultural development has taken place in a particular way; it could not have happened differently. The development that took place over the past decades informs us about underlying forces. These forces will also, and probably more than ever before, determine the panorama of the agriculture of the future.

The structuring moment is located in various 'bodies': in the coercive forces recognizable in the market sphere; in the ongoing technological development; in the complete modernization of our societies, which leaves neither the agricultural sector nor the countryside unaffected; and/or in the sphere of politics. The latter body is usually understood in terms of reflex, in terms of an intermediary between the underlying economic, technological and cultural changes.

In this narrative style, the future of agriculture emerges as a story that 'can be told in advance', as a story that is, as it were, the inevitable outcome of a script contained within the major structuring forces – forces that applied to the past and that will also determine the future.

English colleagues sometimes characterize this by the fine expression 'the race to the bottom'. Agricultural development acts in this script as a process that occurs inevitably via a combination of scale enlargement and rural exodus: less and less farmers, while the surviving farms become larger and larger. Similarly, a continuous industrialization of the interaction with the living world (of 'co-production') is therefore inevitable. One glimpse of the 'bottom' is provided by the frequently produced scenario studies, which speak of a Europe in which 75–80 per cent of rural areas have become superfluous to food production. Similar figures apply to the farming population (WRR, 1992). In other scenario studies, with regard to the Dutch dairy industry, farms are mentioned that carry 1000 cows (LEI/SC, 1996). This would imply only one and a half farms surviving in every rural municipality in The Netherlands.

The 'virtual farmer' acts as the pivot of this script, or rather of all these foresight studies. He (she is hardly mentioned) orients the organization and development of his farm to the laws of market and technology. These 'laws', which are constantly made explicit by the expert system, allow no other course of action than the race to the bottom.

In this book, I attempt to develop a different narrative, a different view. I will demonstrate that there is no structural development, no inevitable race to the bottom. Nor is there a 'virtual farmer', as posited by the knowledge system – and where the sorcerer's apprentice does succeed there is the devil and all to pay.

In other words, this book is an attempt to narrate the story of farmers, agriculture and the countryside in a different way than is by now customary. This conventional story is largely spanned by a number of axioms, by, in other words, a number of institutionalized cognitive models. They concern, inter alia, the farmer as agricultural entrepreneur and the behaviour that he (or she) should therefore display. They also concern the processes that are supposed to characterize the sector as a whole: structural development, rural exodus and the dynamizing role of the agricultural expert system. Furthermore, there are axioms concerning the real nature of farming. Above all there are a number of deeply rooted and widely shared ideas about the future of agriculture. Collectively, these axioms span a worldview (one could almost say a 'paradigm') that I will characterize here by the metaphor of the 'virtual farmer'.[43] This worldview is deceptively consistent. The concepts within it keep presupposing and (re-)confirming each other. To support the logic, the inherent truth, of one axiom it suffices to refer simply to one, or a few, of the other axioms. However, on the whole this is not even necessary. Axioms are self-evident because:

1 they are shared by nearly everyone;[44] that is,
2 they are hardly ever disputed; and
3 neither are they interrupted by a 'stubborn empirical reality', precisely because the same axioms constitute the frame for the perception and the ordering of this reality; hence

4 they span a 'universe of the undisputed': a universe of things that are the way they are because they can only be the way they are.

All this is emphasized by those who do dispute this universe: sooner or later they are exposed as *charlatans*.[45]

However high the theoretical and communicative consistencies, the problem is that this set of axioms no longer corresponds to reality. This need not be a problem if it were not that, first, policy making, implementation and evaluation are consistently informed from the point of view of the virtual farmer, and, second, the same image is a heavy burden on the urgent search for new alternatives for an agriculture that is partly deadlocked within these axioms.

The axioms share above all the common feature that they specify the agriculture of the future. They tell a story about the direction in which agriculture should move. That story is not told, however, in terms of opportunities inherent in the current reality (see Figure 8.1b). It concerns one necessary and inevitable future (Figure 8.1c). This may seem unlikely – the point is, however, that this one future is supported by a series of iron laws contained in the past and the present. The axioms refer to two aspects: they define history thus far as the inevitable unfolding of structural patterns, after which the future is represented as the perfecting of such a process of unfolding.

The cognitive monopoly of the expert system is crucial here. There is only one actor, only one institution, capable of knowing the patterns and hence the future: the expert system in and around agriculture. An expert system that is increasingly forged into a unity, also in organizational terms.

Somos lo que vamos a ser, we are on our way to the future. Future-oriented acting makes us what we are, especially because so many different options, roads, interests and identities are at issue in working towards the future. In the agricultural sector (but probably also elsewhere), however, the future has increasingly been parcelled out, completed and allocated beforehand by the expert systems, which specialise in this activity. And the more the expert systems appropriate the future, the firmer their hold on the 'existence' of those involved, in this case, inter alia, Dutch farmers. All their actions are increasingly conditioned and ordered by the future, which is monopolized by expert systems. Hence, the former are governed by the latter via the future.

This book is a critique of the expert system, of the semi-coherent whole constituted by the Ministry of Agriculture, Nature Management and Fisheries (LNV, *ministerie van Landbouw, Natuurbeheer en Visserij*), Wageningen University, *Dienst Landbouwkundig Onderzoek* (DLO, Agricultural Research Institute) and other research institutes, parts of the Ministry of Housing, Spatial Planning and the Environment (VROM, *ministerie van Volkshuisvesting, Ruimtelijke Ordening en Milieubeheer*), *Dienst Landbouwvoorlichting* (DLV, Agricultural Advisory Service, now privatised as *DLV Adviesgroep NV*), parts of the provincial authorities – in short, by the complex set that interacts with the agricultural sector on the basis of real or assumed knowledge.

I am part of the expert system, in a somewhat contradictory way. Pleasure, curiosity and passion connect me to this larger whole. Yet at the same time I often experience disbelief, rage and disturbance at its shortcomings. In any event, I feel no false obligation to be loyally silent. It is rather my right and my duty (in that respect, I take my job in an old-fashioned way) to criticize when necessary, especially when others are hardly, or not at all, able to do so.

However, let there be no misunderstanding. For – even if I am aware of the conventional classification systems on the shop floor, which divide the components of the expert systems into categories such as 'twits', 'eccentrics', 'dimwits', 'barons' and 'simpletons' (a complex world!) – I argue strongly that we generally deal with very capable and driven people. The failure of the expert system does not concern the qualities of the people involved. What is fundamentally wrong is the way in which we organize and apply knowledge. That is all this book is about. Nothing else.

Storylines

The theme has been clearly defined by now. Five distinctively different storylines can be identified within the described framework. The storylines interweave and interconnect in places. In other places I attempt to develop first this, then another, storyline independently.

The first storyline concerns agriculture as a complex practice – as a carefully coordinated unit comprising (i) the mobilization of resources, (ii) the conversion of resources into end products and (iii) the sale of these end products.

The mobilization of resources is discussed in Chapter 2 in particular. There I point out how, via a lengthy and complex emancipation process, the mobilization of resources (land, capital, labour, knowledge, water, tools etc.) is actively withdrawn from the influence of markets. This distantiation from markets at the input side of the farm provided the basis for the success of Dutch agriculture. Creating a certain distance between farm and markets is one of the hidden ingredients explaining the success of Dutch agriculture. It is also one of the ingredients that is systematically ignored in the currently predominant description of the virtual farmer. Farmers act as *Homo economicus* within the image produced by the contemporary agricultural knowledge network, as entrepreneurs integrating their farm fully into markets and therefore following and implementing the logic of the market: as puppets on a string.

Dutch farmers are, I will argue in this book, not so much the entrepreneurs they should be according to the agricultural expert system, but peasants: producers who, for the sake of their own survival, actively withdraw the processes of farm management and farm development from the logic of markets that seem to ignore their survival.

'We have never been modern', according to Latour in a well-known essay (1994). In its footsteps one could claim: 'Dutch farmers have never been entrepreneurs' (which in fact has already been raised by Constandse in 1964). They are peasants, and precisely because they are peasants they have proved to be so successful through the ages. The fact that this is also extremely topical and relevant nowadays is discussed in Chapter 5.

The transformation or conversion of resources into end products is discussed at length in Chapter 4. This transformation (for example from grass and cows into milk and meat) is conceptualized in the agricultural expert system as regulated by production functions: a fixed relationship between inputs (grass and cows) and outputs (milk and meat). It is assumed that new, more productive and/or more sustainable production functions can only be created after technological breakthroughs.

In contrast to this thesis, I want to develop another image. Indeed, there are regularities and patterns of coherence. Unmistakably, the relation between inputs and outputs (the I/O relation) displays a certain range and contains a certain, as yet uncrossable, frontier function (the most efficient I/O relation) in certain, temporally and spatially restricted situations. But what is important here is that these patterns or regularities are a product, a result of the labour process in agriculture. Furthermore, I regard the labour process as locus of co-production, of the continuous encounter between, and mutual transformation of, the social and the natural. Precisely because the results of this co-production are rooted in, and arise from, the labour process, it will always involve extremely variable I/O relations. New production functions are constantly created in and through the process of farm labour: new patterns of coherence that correspond closely with farmers' own interests, perspectives, insights and knowledge.

In previous studies of farming styles, researchers concentrated initially on the above-mentioned dimensions: the conversion and mobilization of resources. This initially limited approach was later broadened, thanks to the work of Kerkhove (1994), Ventura and Van der Meulen (1994), De Rooij et al (1995), Wiskerke (1997), Van der Meulen (1999a, 1999b) and Roep (2000). The studies identified the sale of end products and, hence, the specific circuits connecting production and consumption as ordering principles, as essential types of interlocking, and therefore as crucial parts of socio-technical networks. I will return to these new insights in Chapter 9, where new development opportunities for Dutch agriculture will be discussed.

What is important in this first storyline is that the interconnected domains of mobilization, conversion and sale contain considerable variability – each separately, but above all collectively. They are malleable, flexible, changeable. The resulting variability cannot be understood as a 'fixed' range: it is constantly enlarged in the practice of farming – that is, by farmers' innovative capacity.

Similarly, the potential variability is constantly restricted, if not reduced. If two keywords describe agricultural history and its development of production capacity, they are variation and selection. On the one hand, there is a constant search for new patterns, and for new combinations, to further increase the already available variation. On the other hand, some patterns, and some combinations, demonstrate that they are more successful than others, while others prove unsuitable in the light of changing social and ecological conditions. Thus selection appears, while the provisional end result of the selection is the starting point for the search for and creation of new variation.

Farming is like 'a dance through time': time and again variation and selection result in new socio-technical networks, new types and connections. While these new expressions emerge, others degrade and disappear – sometimes stealthily, almost unnoticed, at other times abruptly.

This brings us to the second storyline. It concerns the heterogeneity of farming as the (temporally and spatially confined) expression of this 'dance through time'. In Chapter 3 of this book, I will discuss in detail the farming styles that can be distinguished in contemporary Frisian dairy farming. I will try in particular to describe these styles as projects, as 'self-reflective strategies for patterning the network of the social' and, hence, as part of a more comprehensive socio-technical network.

The remainder of the book builds upon this, particularly Chapters 6 and 7, which discuss selection, and Chapter 9 in which variation is discussed. More precisely, in Chapters 6 and 7, I analyse the interaction between the development opportunities inherent in various farming styles and the dominant agro-political project – that is, the process of modernizing agriculture – while the interaction with a new agro-political project, in which rural development has a central role, is analysed in Chapter 9. Chapter 8 forms a link: there the central theme is the extensive erosion of trust, the essential ingredient in the functioning of expert systems.

The third storyline can be summarized as a systematic critique of various forms of determinism: of technological determinism (in Chapter 4, inter alia, where the doctrine of production functions is discussed); of economic determinism (in Chapter 5); but especially of what is called structural determinism, which has overrun the social sciences (including rural sociology). Chapters 6 and 7, which discuss modernization as 'the unfolding of structural patterns and relations', can be understood as a critique of structural determinism. There the agricultural knowledge system, the expert system that represents, propagates and realizes this structuralist notion like no other, is discussed at length.

The fourth storyline is the obvious counterpart of the third: it entails a search for a more adequate concept of structure. I have already commented on it in this introductory chapter. In this book, I will test the concepts and notions raised in this chapter, to arrive at a conclusion in the final chapter (Chapter 10). I will also summarize the critique of the contemporary expert system in Chapter 10. Chapter 9 forms an important prelude to this, which brings us to the fifth and final storyline. Chapter 9 concerns new development opportunities that reach beyond the current misery. In the discussion of these opportunities, I use 'rural development' as the connecting concept. Chapter 9, the 'battle for the future', is also concerned with the social and political struggle that was waged in the 1990s over the realization of new development opportunities.

Notes

1 Incidentally, the full text runs as follows: '*vivir es constantemente decidir lo que vamos a ser*'. The author states further: '*nuestra vida es ante todo toparse con el futuro … la vida es una actividad que se ejecuta hacia adelante, y el presente o el pasado se descubre después, en relación con ese futuro. La vida es futurición, es lo que aun no es*' ('life is above all dealing with the future … life is a progressive activity, and the present or the past is discovered with hindsight, in relation to the future. Life consists of making futures; it is what it is becoming'; Ortega y Gasset, 1995, p228). For a further comment, see Remmers, 1998, chap. 7, esp. pp313–317.

2 I am acutely aware that it is easier to speak about the great period of modernization than it is to define the period. Two issues are clear. First, the era of modernization was constructed only gradually in civil society as a whole. The rise of capitalism – initially in the Italian city states, later in The Netherlands – and the subsequent civil revolution in France, the Enlightenment, and the industrialization that started in England all represent many stages in this protracted process. Second, it is clear that the same process of modernization occurred in agriculture much later than in the urban sphere of influence, although it is not clear exactly where and when to situate the turning point. The work of Hofstee is a case in point. In his 'early' work Hofstee (1946, 1985) located modernization (the turning point from a traditional to a modern-dynamic cultural pattern) in the first half of the 19th century. Furthermore, he sometimes refers to the early Middle Ages and to the periphery of the then feudal systems as the cradle of modernization. In his 'later' work (see, for example, Hofstee, 1953) the post-war period of the 20th century acts as the turning point. The identification of the turning point is, as is well known, highly controversial. Historians such as Van Zanden (1985) and particularly Bieleman (1987) have indicated that in the olden days agriculture already showed remarkably 'modern' features. Be that as it may, it is striking in this controversy that no one disputes the difference between 'traditional' and 'modern'. The big question is where, and particularly when, to situate the beginning of certain phases.

3 Again, it is not my intention to look for clear boundaries in time, hence the use of the vague description in the main text. Incidentally, it is remarkable that this 'next phase' started earlier in agriculture, so it seems, than in the rest of society. See in addition Chapter 6, where the functioning of the expert system in agriculture is described.

4 As I will demonstrate below, we should perhaps say: in that which specifies our future. The contemporary expert systems are more than just a collection of scientists, specialists and experts. They are also the paramount prisoners of the axioms that regulate knowledge production.

5 James Scott relates the phenomenon of mega- or macroprojects largely to the functioning of the contemporary state. Thus, he interprets megaprojects as 'state simplifications'. These simplifications (as such inherent in the functioning of bureaucracies) 'do not successfully represent the actual activity of the society they depict, nor are they intended to; they represent only that slice of it that interests the official observer… [They are simplifications] that, when allied with state power, will enable much of the reality they depict to be remade' (1998, p3). Scott points out that the development of megaprojects ('the tragic episodes of state-initiated social engineering') arises from a combination of four elements: the 'administrative ordering of nature and society', a 'high-modernist ideology', an authoritative state ('willing and able to use the full weight of its coercive power to bring the high-modernist designs into being'), and finally 'a prostrate civil society that lacks the capacity to resist these plans' (1998, pp4–5). Indeed, those seem to be the required and necessary conditions with respect to the cases Scott analyses. However, if we introduce the modernization of agriculture into the analysis, these conditions appear insufficient. Agricultural modernization as a megaproject takes place (just like various other contemporary macroprojects) under *democratic* conditions, which refers indirectly to the considerable influence obtained by and assigned to the expert systems.

6 This has been described at length in general terms by Callon, 1986; Bijker and Law, 1992; Latour, 1994; Lowe et al, 1995.

7 The communication between farmers from various regions is a shining example of this. The 'other' was not taken note of in order to imitate but rather to understand better and, if possible, to strengthen what was one's own. If parts were adopted from elsewhere, its structure would typically be 'one's own' – that is, that which was constructed and expanded thus far, the frame from which to assess what could possibly be adopted and how it could be fitted in. (For a further analysis, see Van der Ploeg, 1987, esp. pp35–42.) It is remarkable that the 'grammar' of comparison and adoption has radically changed since then (Cristovão et al, 1994). At present, there is a clear hierarchy of 'most developed' agricultural systems and of more or less 'underdeveloped' agricultural systems. The technologies of the former now hold as the normative frame around which the agricultural practices of the latter have to be reorganized. 'Areas lagging behind in development', the term frequently used within the EU, is a striking expression of this.

8 See Long and Van der Ploeg, 1994, pp80–81.

9 This term is used to indicate the opposite of 'interlocking'. Distantiation represents creating a distance, creating room for manoeuvre or autonomy.

10 Robinson Crusoe's project, to mention probably the worlds' most famous castaway, could only succeed with the presence of the stranded ship – resources! – and with the arrival of Friday.

11 Trust emerges as one of the important mediums to cement postmodern societies together, and as a vehicle to implement developments. Trust is (in contrast to faith and confidence) highly depersonalized. It is institutionalized faith in a system and its artefacts and procedures. Trust implies that carrying out certain actions will lead to a future situation specified beforehand. If the latter situation is the objective and if the actions to be carried out are the means, trust integrates the two. If I want to cross a busy and dangerous road, pressing the button at the pedestrian crossing and waiting for the lights to change to green are the means by which to safely reach the other side (the objective; Giddens, 1990). As a pedestrian, I do not have to know the different drivers (or look deep into their eyes). I trust not so much the drivers as subjects but the 'system'. I assume that the other participants (the drivers) do the same. The knowledge that everyone acts on the basis of the system generates trust, just as the functioning of the system presupposes trust. The same example makes clear that a simultaneous coordination of various actions is necessary to realize trust. Drivers will have to stop when the lights change to red. If they want to meet their objective (let us at least hope that this consists partly of avoiding accidents), acting on the system of traffic rules (stop at red, go at green) is a necessary means for them. Trust connects everything. Without trust the system (the set of traffic lights and rules) will not work at all.

12 This trust in systems includes primarily 'the faith that a role is interpreted according to the norms, *more or less independent of the person performing the role*' (Galjart, 1998, p13, my emphasis). Galjart contrasts this trust in systems with what he calls 'particularistic trust': 'the expectation that *someone else* will cause us harm in a transaction or a relationship' (Galjart, 1998, p12). In his discussion, Galjart considers the crucial importance of trust for development.

13 If collective memory is the subject in traditional societies, just like agency in the era of modernization, the expert system is the most important subject under postmodern relations.

14 But it is possible in the long term, see Groen et al, 1993.

15 For a theoretical explanation, see Wiskerke, 1997.

16 It is no coincidence that I refer here to Harris. From his pen comes one of the most eloquent critiques of the approach that we have tried to develop in Wageningen. In the proceedings of the 50th anniversary congress of Wageningen sociology (where Harris unfolded his critique), Long and Van der Ploeg discuss the critique at length.

17 What remains intact is that one can of course use a conceptual framework in which 'external structure' acts as a causal complex. Thus emerge the so-called structuralist theories. The bankruptcy of such approaches has been amply exposed, by Long (1985) in particular.

18 The same applies to Booth as to Harris. From his pen comes an inspiring critique, a heartfelt search for the possible weak points in the Wageningen approach. Just as in Harris' case, Booth's observations revolve particularly around the question whether an actor-oriented approach excludes the concept of coercion (whatever its nature or form). See Booth, 1994.

19 Of course, the relations at issue here (the relations among various projects) can differ considerably. Some will be extremely hierarchical and coercive. This does not imply, however, that one therefore needs to fall back on structuralist approaches; I attempt to show this in Chapter 6 by means of the so-called structural development of and in Dutch agriculture (as a result of which more than half of the farmers had to abandon their farms).

20 Following the work of Giddens, it is tempting to locate such incapability in 'structure' (in its Giddensian sense). For structure is not only enabling but also constraining. It excludes certain types of action, certain manifestations of agency, while others become possible. Theoretically, this solution is hardly satisfactory – empirically, it is unmanageable, as will be shown in note 21.

21 If one looks at contemporary Dutch agriculture, the complications can be seen a mile off; because there is no other possible interpretation than that agency is ubiquitous. In any case, the presence of farms, of whatever farm, is inconceivable without the notion of agency. If, in the previous period, there had not been a determined effort to continue the farm and if one had not succeeded at this, there would be no individual farms nor a collection of farms as a whole. Every farm is evidence of the 'capability of doing things'. In agriculture (and I assume the same applies elsewhere) there are no actors walking around in a permanent comatose state. This notion of structure could be introduced as the counterpart of agency. Apart from the extremely difficult question of what should be interpreted as structure, a not very satisfactory dichotomy would emerge here. Structural relations (as 'both enabling and constraining') imply that a number of farms are doomed to vanish, while others can continue (for the time being). The notion of non-agency would apply to the first group, and agency would apply to the second group. Such a dichotomy is completely unsatisfactory. First, because it ignores, on the one hand, the fact that a number of farms are purposefully abandoned (not only intentionally, but also through the corresponding actions), and, on the other, the situation that a great many farms are continued purely as a matter of routine (see, inter alia, De Bruin, 1991, who discusses the problematic aspects of farm succession). Second, it is unsatisfactory because it is hard to understand why and how 'structurally impossible farms' (let me put it in that way for the time being, I refer especially to small or even very small farms) are sometimes continued or even guided along the cliffs of a very difficult farm transfer. If 'structure' is 'constraining' in some cases, it must be in every case; because if it does not do so in some cases (because dominated by agency), the notion of actor-structure as duality becomes very problematic. Third, I want to point to the fact that there is an impressive degree of differentiation among the 'remaining' farms; in other words, agency can result in innumerable 'things', or else various types and degrees of agency should be introduced. In short, I think that agency as an undifferentiated concept, as the opposite of structure, is very unsatisfactory.

22 In other words, Law's principle of symmetry (1994) can and must be applied here as well.

23 This does not imply that these notions, or images of the future, are *always* fluid, are always *variable* and *changeable* in empirical reality. The crux of the large macroprojects and of contemporary expert systems emerges here: they *make* the images of the future rigid and unchangeable.

24 Because on the whole, cohesion, fabric and web are very remarkable. More obvious perhaps are disintegration, the inability to coordinate, ignorance, and so on. Rather than simply taking cohesion for granted, it should be explained.

25 Van der Ploeg (1993) explains in more detail how difficult, if not improbable, it is to innovate under contemporary conditions.

26 For example *Adellijk Bloed* by Popta (1962). There is also an incipient critique in there about the expert system that was beginning to emerge in the world of livestock breeding.

27 This is the comprehensive 'modernization project' that was conceived and also materialized in Dutch agriculture from the 1960s onwards. For more detailed descriptions, see Frouws and Van

der Ploeg, 1973; Van der Ploeg, 1995, 1996. It may seem confusing at first that I present and analyse this 'modernization project' as a shining example of a 'postmodern' approach. Just as in the social sciences (see earlier in this chapter), however, it applies here that one's own projects are decorated with the colours and terms of the past. Agriculture had of course been modern for a long time before mid-20th century. See the convincing work of historians such as Bieleman, 1987. Hofstee's work (1985) is significant in this: he shows how a 'modern cultural pattern' emerged in the clay region of Groningen in early 19th century. However, as if this had never happened, the induced changes in the latter half of the 20th century are just as easily called 'modernization'. If one takes a magnifying glass and watches various processes, it would show that the term repeatedly re-emerges during and after this period. Time and again, the 'need for modernization' is mentioned: at every land consolidation, at every adjustment in arable agriculture, at every introduction of new technology, every time one has to face adverse market conditions. The power of the word is probably in the suggestion that undesired situations can be overcome once and for all in a single operation.

28 See, inter alia, Van Egmond et al, 1996; Nijhof et al, 1996; Langman et al, 1997.

29 The greatest upheaval emerges, I know this from my own administrative experience, if one allows participants other than the usual ones to join the conversation about the definition of the 'agenda'. Conversely, many examples in and around agriculture and the countryside indicate how certain voices are regrettably turned into a predominant, if not the only possible, routine.

30 In other words, one should avoided equating the eventual ordering, or its effects, with the initial mode of ordering/strategy as such. In those cases where Law speaks of 'imputation', such a danger becomes far from imaginary. What occurs as 'practice', as state of affairs, as material *effect*, at moment T and in place P will never be the unilinear effects of one mode of ordering, of one strategy, but rather of the encounter, the interaction, the mutual influencing, conditioning and often the mutual transformation of several modes of ordering, i.e. several strategies – of several interlocking projects. However, Law does indeed hint at this, for example when he discusses 'interordering effects' (1994, p22). The empirical setting within which Law conducted research (one large laboratory) was probably less encouraging to further explicate the issue touched on here.

31 In the fourth chapter of his study, Law presents four modes of ordering: enterprise, administration, vision and vocation. He stresses that they cannot be defined in terms of persons, or in terms of personal attributes. They are strategies. It is the same point with which we have often struggled in the farming styles group. For the sake of recognition, we have modes of ordering reduced to and attributed to nouns instead of verbs. In English texts, however, this is not the case. There, for example, 'the strategy of farming economically' is used consistently, rather than 'economical farmers'. In Law's analysis, those four modes of ordering are present in constantly changing combinations in the laboratory. The great difference is, of course, that agriculture is concerned with sole proprietor businesses. Therefore, there will rather be only one style, only one strategy, on family farms. (However, partnerships and corporations are interesting phenomena; in the case of several siblings, you will certainly find that one pursues one strategy, the other pursues another. Furthermore, there is of course the tension between men and women: various principles that are balanced against one another. See De Rooij et al, 1995.) Law stresses that enterprise and administration are antithetical modes of ordering. This emerges notably from various farming style analyses too. The 'economical' versus the 'ambitious' (to elaborate on one's own resources versus to mobilize as many external resources as possible; see Van der Ploeg et al, 1992). The same applies to the styles of cowmen *vs* machinemen; as well as to skill-oriented *vs* mechanical technologies (Bray, 1986) and to intensity *vs* scale (Van der Ploeg, 1987). Thus a mutual, although ever changing, influencing of modes of ordering occurs within the laboratory. Furthermore, Law shows that interlocking with projects (or modes of ordering) of clients, financiers, ministries, universities etc. is also going on. All in all, 'interactive systems' (Booth, 1994), i.e. 'interlocking projects' (Long and Van der Ploeg, 1994), become decisive.

32 In short, the 'network' cannot be understood simply as an aggregate of modes of ordering. All the more because the 'patterning of the social' (certainly in the current postmodern constellation) increasingly defines which modes of ordering, which strategies, do or do not fit. Here too the turning point, to which I referred previously, appears again.

33 All in all, financial capital represents nothing more than a particular project: to increase the initial amount of capital through participation in other projects.

34 A definition in terms of 'feasibility' is also important: What can I exercise influence over? What is beyond my power? 'Feedback' is already integral to all this: as part of the decision of what is relevant to me (and definitely in the further specification of what I could influence) I will have to take account of the world as it presents itself to me and/or of the world as it is presented to me. *Yo soy yo y mi circunstancia*, as Ortega y Gasset (1995) states in this context: 'I am myself and my situation.'

35 These are the terms suggested by neo-institutional analysis as solutions to problems such as those described here (see, inter alia, Saccomandi, 1991, 1998).

36 In fact, this continued to the extent that the building of the factory had almost been finished before the third partner, Friesland Coberco Dairy Foods, decided to participate. I think it goes without saying, therefore, that considerable risks have been taken along the entire trajectory. On the other hand, as Henk Brouwer argues, you 'need to be able to fall back on a number of side streets. If you can't turn left, you'll have to be prepared how to turn right if necessary'.

37 Even though leading thinkers of the Rabobank in Utrecht (its headquarters), such as Wijffels and Krouwel, supported the initiative wholeheartedly, the Eindhoven office (where credit applications are eventually assessed on the basis of formal criteria) reached a negative decision. It was reasoned that dairies were being closed all over Europe, and it was therefore ludicrous to think that a small dairy such as the FEZ would stand a chance of survival. Eventually, the Rabobank did become involved in the FEZ indirectly through Rabobank International.

38 Friesland Coberco Dairy Foods had attempted years before to set up a range of organic products. However, it had turned out to be a total flop. A new initiative by a 'small outsider' was initially regarded as rather painful: 'If we can't do it, nobody can.'

39 The Industry and Commerce Board was notable by its absence in this innovation. It is also typical that serious practical research on organic dairy farming by the expert system only started during 1998–1999. For that is the moment when institutionalized practical research (*in casu* Aver Heino) makes a changeover. It means that the first results will only be available in five years time, i.e. in 2003 or 2004.

40 The alleged backwardness became even the conceptual starting point of operationalizing the countryside and, therefore, of differentiating it from the city (see Van der Ploeg, 1997).

41 Of course, other large megaprojects did exist. In The Netherlands, they included the organization of water management, coastal defence and energy supply. It is well known that each of these represents so much as a state within the state.

42 After all, you cannot experiment simultaneously with Schiphol Airport in the North Sea, Schiphol in Flevoland (or in the Markerwaard), and the expansion of the existing Schiphol.

43 If there is anything in this world that can hardly be virtual, it is a farmer. Farmers stand in the mud, between their cows. Or they watch the latest version of a milk robot at the Agricultural Show. However, they watch all this knowing that milk will soon have to flow into the jars. In our 'virtualized world', farmers are probably the last junction of its stubborn opposite: it starts off on matter, on mud and cows, and it ends in matter, in milk or in seed potatoes. Hence, it is out of the question that there is or could be any detachment and evaporation of things into words and symbols and nothing else.

44 The 'old boys network', which clearly exists in the agricultural knowledge network or 'expert system', centres largely on aspects of one and the same set of axioms.

45 Recent agrarian history has a painful flip side, related to the 'conversion' of critics and innovators into 'charlatans'. Older colleagues have told me many stories about this. I leave the retelling of those stories to the first agrarian historian who dares to research a really controversial issue.

Diversifying Rice-based Systems and Empowering Farmers in Bangladesh Using the Farmer Field School Approach

Marco Barzman and Sylvie Desilles

Over the past eight years, CARE-Bangladesh has been developing a set of sustainable agriculture projects to improve production in rice-based farming systems in this country. These efforts have contributed to an emergent programme to increase food security for poor and marginal farmers. The programme raises agricultural productivity by diversifying agroecosystems and optimizing yields, reducing costs of production and creating new income streams.

Although the programme is associated with a number of agricultural techniques that are readily adopted and disseminated, it strives to achieve more than the simple transfer of sustainable agriculture technologies. It follows a philosophy of adult education that emphasizes personal experience and builds up people's confidence and ability to manage their future development (Hagmann et al, 1999). The main difference between this and other agricultural development programmes has been its emphasis on knowledge and experimentation, rather than technologies and material inputs. The programme enables farmers to take initiative in experimenting with and understanding ecological processes in their fields.

These principles and methods have been developed as part of a regional programme to refine and spread Integrated Pest Management (IPM) practices within Asia, supported since 1982 by the UN Food and Agriculture Organization (FAO) (Röling and Van de Fliert, 1994). This chapter reports on experience in Bangladesh, focusing on the programme's philosophy and operation as well as its results.

Reprinted from Barzman M and Desilles S. 2002. Diversifying rice-based systems and empowering farmers in Bangladesh using the Farmer Field School approach. In Uphoff N (ed) *Agroecological Innovations*, Chapter 16, pp203–211, Earthscan, London.

Programme Overview

The rice programme in Bangladesh has had two aims: to increase rice field productivity and to empower farmers in terms of their decision making and management capacities. The rice field is the main source of revenue for the category of small farmers targeted by the projects. Appreciating this, the programme seeks to enhance the capacity of households and communities to independently generate, access and disseminate knowledge. This is achieved through the facilitation of a team of skilled and motivated staff who are given the task of creating an effective learning environment in which farmers test a variety of sustainable agricultural practices.

The dual objective of exposing farmers to agricultural innovation and of empowering them is achieved through the creation of Farmer Field Schools (FFS) adapted from experience in other Asian countries (Kenmore, 1997). Important elements of the approach adopted by CARE-Bangladesh include the development of a broad curriculum that focuses on the entire rice cropping system and provides farmers with a 'menu of topics' to choose from, and an experimental approach in which farmers are considered researchers (Kamp and Scarborough, 1996).

The agricultural techniques in the programme have been:

- sustainable agriculture practices in rice;
- vegetable production on rice field dykes;
- fish production inside the rice field;
- production of fish fingerlings;
- tree planting on rice field dykes.

These practices increase rice-field productivity through optimized use of the natural resources available. The way in which these practices are learned is intended to result in a certain level of farmer empowerment.

An innovative, field-tested model for adult education has been developed through experience with three related projects supported by the UK's Department for International Development (DFID) and the European Commission. The programme during its initial phase (through 2000) involved around 150,000 farmers. The second phase, now started, disseminates this model to other organizations, non-governmental and governmental. It expects to reach more than 1 million farmers within the next six years. The activities of the expanded rice programme will include more emphasis on homestead gardening and vegetable growing.

Impact on Farmers

The core agricultural practices of the programme – sustainable rice production, rice–fish farming, vegetable dyke crops and trees on dykes – aim at sustainable and optimal land use, a fundamental issue in rural Bangladesh. Households with limited access to land need farming systems that generate more income and food in an efficient, reliable and sustainable manner.

Rice Production

Between 1995 and 1998, small-scale rice growers in the project areas obtained 4.7 and 3.2t/ha yields in the dry and monsoon season respectively (n = 2927).[1] Data from 1995 to 1997 show that project participants generate yields that are on average 4 per cent and 11 per cent higher than non-participants in the dry and monsoon seasons respectively (n = 1640). This was achieved mainly through changes in fertilizer and pesticide use, transplanting time, spacing, variety, and seed and seedling quality. While these increases are modest, they combine with reduced production costs to raise household incomes.

Most of the reduction in production costs is from reductions in insecticide use. In 1999, for example, the percentage of participants using insecticide on their rice at least once dropped from 86 per cent (n = 6045) in 1995 to 11 per cent (n = 7700) in the dry season, and from 76 per cent (n = 6045) to 19 per cent (n = 7700) in the monsoon. We estimate there have been savings of 486 takas per 0.11 ha plot (n = 360), which amounts to 4418 takas per hectare per year (US$92).[2]

After having obtained yield increases, farmers become willing and able to spend more on quality seed of improved or local varieties or to produce and preserve their own seed. In the highest external input use district, the percentage of participants producing their own rice seed went from 40 per cent to 83 per cent (n = 200 respondents from 21 FFS) before and after project intervention. Irrigation costs do not change, while labour costs increase slightly as farmers give more importance to certain crop management practices such as planting in rows and weeding. Overall, the costs of production for dry season rice decreased by 12 per cent, from 1.70 takas per kilo of rice produced (baseline) to 1.40 takas after two years. For monsoon rice, the per-hectare costs of production declined 30 per cent, from 1.30 takas to 0.90 takas per kilo of rice produced.[3]

For farmers, the other main consideration in rice production is reducing year-to-year yield fluctuations. Participating farmers have developed the capacity to maintain a minimum threshold of production from their rice fields while reducing their costs of production. This is essential to food security. Farmers working with the project experienced variation in yield averaging plus or minus 5 per cent, while control farmers experienced average variances in yield of 9.5 per cent.[4] The data from pairs of farmers matched by rice variety and irrigation source during seven seasons between 1996 and 1999 show that the total crop failure rate of participants was 0.3 per cent, while that of control farmers was 0.54 per cent (n = 1673 pairs of farmers).

Other Production Within the Rice Farming System

The programme is also promoting the integrated cultivation of rice, fish, dyke crops and timber trees. As rice is the staple food in Bangladesh, and also probably due to the influence of the Green Revolution, farmers invest considerable time and effort in rice while neglecting other crops. By introducing other crops within the same field and managing them through an ecological approach, farmers are able to lower their dependency on rice both as a crop and in their diet.

Throughout the year, farmers participating in the programme harvest vegetables and fish in addition to rice from their fields. They sell and consume these products in varying proportions depending on their needs and their production. The cost of production of these complementary crops produced in the rice field is minimal, and rice production remains the same or possibly increases (Barzman and Das, 2000).

Rice–Fish production

The number of farmers who produce fish in their rice fields varies from area to area depending on the local physical characteristics of the soil and the water management. By the end of 1998, 30 per cent of participating farmers (n = 11,383) were experimenting with this technique, and data taken two-and-a-half years after project intervention show that their numbers actually increase after the initial trial phase. Farmers practising this technique dig a small ditch in the corner of the field to provide shelter to fish that they introduce as fingerlings at the beginning of the season. The fish find their own food within the rice field, making their maintenance cost negligible. In the case of the higher valued native fish species, the main cost of production is the purchase of fingerlings. For common carp, on the other hand, farmers typically produce their own fingerlings.

Most of the labour in this fish production system concerns the raising of dykes and the digging of the corner ditch. The cost of water can be considered a rice production cost. Usually, family members take care of these complementary production activities. In 1997, the average cost of production of fish per rice–fish plot (n = 212) was 791 takas per year, which is equivalent to 5271 takas per hectare (US$110). All rice–fish farmers consume a part of the harvest, and most also sell the remainder.

In 1997, after production failures were excluded, the average annual potential net return per farmer was 6241 takas (n = 212), which is equivalent to 53,290 takas per hectare (US$1110).[5] Some rice–fish growers make extra income and reduce their fish production costs by producing and selling their own common carp fingerlings during the irrigated rice season. By the end of 1998, 33 per cent of participating farmers (n = 11,383) were doing this and obtained on average 609 takas per farmer (US$13) from their sales of fingerlings.

Rice and dyke crops

Vegetables can be grown on the dykes surrounding the rice field if these are raised and widened. With this technique, project participants have been producing country bean, yard-long bean and a number of squash species that are planted in small pits filled with compost. In 1998, the average potential net return from dyke crops is 1470 takas per farmer (n = 145).[6] This is equivalent to 9800 takas (US$204) per hectare of rice land over the year. The inputs required are mainly seed, organic compost for pit preparation and labour. Farmers usually just use a portion of the fertilizer that they have purchased for their rice production on their vegetable dyke crops and the organic compost is produced at no cost.

Vegetable seed is increasingly produced locally at no financial cost. One study conducted in the highest external input use district showed that the number of women participants producing their own vegetable seed went from 26 per cent to 69 per cent (n = 200 respondents from 21 FFS).[7] This helps to make the activity reasonably remunerative.

Trees on dykes

There are cultural practices, such as periodical pruning of roots and branches, which make it possible to grow trees on the dykes without affecting the rice crop. This type of pruning is not favourable to fruit trees but is perfectly appropriate to trees producing timber, cooking fuel and fodder. In December 1998, 28 per cent of project farmers (n = 19,450 farmers) were experimenting with this technique. We have observed that two years after the project had left, farmers continue to tend their trees. It is too early to evaluate the economic benefits of this technique, but we are already observing that the number of farmers planting trees on their dykes is growing and that many have initiated small-scale tree nursery businesses to supply their community with the required tree saplings.

Rice–fish–dyke crops

Since the integrated system does not decrease the yields of any one component, rice farmers who integrate fish and dyke crop production naturally compound their net returns. Already, 20 per cent of the poor and marginal farmers in the programme have adopted this combined practice.

Overall Economic Impacts

The exact economic impact of these practices on households is difficult to assess. The figures given above are based on a single 0.11ha plot whereas our participating households own about four plots averaging a total of 0.45ha on which it is impossible to say how many of the innovations are practised. Another difficulty is that households consume much of the increased production as food and donate a significant portion to relatives and neighbours, making an economic analysis nearly impossible. Even if the actual returns per household attributable to the innovations were known, we still would not know how much this would represent relative to the total income of the household and its needs. Nevertheless, the high adoption rates of the new practices make it clear that they make economic sense.

Non-economic Benefits

Measurable economic returns represent only a fraction of the benefits generated by the programme. Households and communities also benefit from improved nutrition, decreased environmental degradation and empowerment.

Nutrition

Our indicators of diet show that the project contributes significantly to improving project participants' nutrition. The project is helping to reduce over-reliance on rice by increasing vegetable and fish consumption. We find that after project intervention, the relative number of project households consuming vegetables every day doubled while those consuming vegetables only once a week decreased 12-fold. Similarly, the number of households consuming fish every day more than doubled while those consuming fish only once a week decreased nine-fold. And lastly, the amount of edible oil used by households – a good indicator of the total amount of food cooked – increased by 21 per cent on average.

Environment

It is well established that simply foregoing the use of insecticide dramatically increases the abundance of beneficial insects and will reduce farmers' and consumers' exposure to hazardous chemicals (Pingali and Gerpacio, 1997). The reduced reliance on insecticide is long lasting. Our post-project survey shows that even two-and-half years after project intervention, 77 per cent of participating farmers (n = 1200 farmers) continue to grow rice during the dry season – the high input season – without using insecticides, a long-term change up from 14 per cent before project intervention (n = 400 farmers). Another intervention with a probably significant impact on environmental sustainability is the planting of trees on dykes. Trees add a structural dimension to the rice field and provide refuge to many life forms. The data set just mentioned also shows that two-and-a-half years after phase-out, 41 per cent of FFS participants (n = 1200 farmers) still have trees growing on some of their dykes, a technique totally unknown before project intervention (Barzman and Banu, 2000).

Empowerment

Through farmer involvement, the programme hopes to strengthen the capacity of farmers and their communities to continue to innovate and to respond to future challenges without requiring project intervention (Röling and de Jong, 1998). With a better understanding of the agroecosystem and familiarity with the experimental method, farmers build up their confidence in their own knowledge, learning capacity and decision making capabilities. Field staff who work directly with farmers have no doubt that the programme does achieve this other objective. Yet this is a difficult entity to quantify.

There are signs that, as a result of project intervention, farmer innovation is taking place. Some participating farmers moved beyond the 'prototype techniques' and adapted them to suit their own needs. For example, there are farmers now experimenting with the cultivation of shrimp instead of, or together with, fish. They develop their own knowledge by studying shrimp production by larger producers, asking questions and using their neighbours and other members of the group as a source of knowledge. Whereas the programme focuses on the use of common carp – an exotic but easy-to-rear species – as the fish species of choice, many farmers are producing native species, including some that are endangered. The same is taking place in vegetable dyke crops where farmers are trying vegetable species not associated with the programme. Some farmers have taken the vegetable crops and planted them around the homestead or along roadsides and the same is true for trees originally intended for dykes.

Another indicator of empowerment is the level of organization and collective action. Some FFS, independently of project staff, have formed formal grassroots organizations. The potential impact of these organizations is great and the programme will study their development as a first step towards enhancing this process. Already, some farmer groups have taken collective action in marketing their products. Others are producing fish in large areas made up of a number of adjoining individual fields in which fish fingerlings are jointly procured and from which returns are shared among the group.

Within the FFS, farmers experiment and compare their results. They observe and monitor other farmers' fields where organizations have already installed demonstration plots. FFS participants are better able to evaluate new technical options presented by agricultural researchers or extension services. They are also more critical of proposed new technologies.

The project is also contributing to the empowerment of women, who in rural Bangladesh are confined to the household and kept away from sources of power. The project encourages women to work away from the homestead in the rice field. One survey showed that two-and-a-half years after the project's departure, 74 per cent of them were still tending vegetable dyke crops and all of them were involved in rice–fish culture (n = 1200 responses). Farmer leaders, half of whom are women, receive additional training and subsequently serve as resource people in their communities. Such women often report a newly acquired sense of worth and enhanced social status. Some of these women have been elected to the local government.

Lessons from the Rice Programme in Bangladesh

After eight years of programme implementation, some valuable lessons have emerged. The programme, which can be considered successful on several levels, has received regional and even international recognition. Some of the operational reasons for this success include the following:

- Projects sought ways to place farmers in the centre of the learning process and enabled project staff and farmers to communicate productively in spite of major soeioeconomic differences between them.
- The experiential approach, by treating the farmer as a researcher, created an environment conducive to learning and confidence building.
- Projects used sustainable agriculture techniques modified from native practices that had already been intensely tested and therefore presented minimum risks to subsistence farmers.
- Men, women and sometimes children from the same household were provided with training to ensure support from within the family.
- Working with groups on collective activities has meant a better use of resources, increased sharing of knowledge, better coordination within the community, and more acceptance of women's involvement.

The programme developed several strategies to promote wider acceptance of women working in rice fields. Staff had to be willing to learn and be flexible enough to regularly modify strategies, and a system was developed that enabled farmers to conduct their own monitoring and analysis of results.

Difficulties Facing the Programme

The success that the programme has met with respect to its objective of increasing rice field productivity has overshadowed its other objective: empowering farmers. Both farmers and staff tend to focus on the relatively rapid agronomic results obtained. And since the agroecological conditions in Bangladesh are rather homogeneous, the same agricultural practices tend to yield similar results in different locations. Because of this, projects tend to become promoters of a technological package which, even if itself sustainable, is not conducive to sustainably increasing farmers' decision making and management capacities.

The agricultural practices associated with the programme were designed as *entry points* to obtain quick results and from which projects could move on to long-term changes. But they sometimes become an end in themselves in a way that is reminiscent of the old transfer-of-technology extension model. Obviously, farmers' needs are connected to the opportunities that exist in their area in terms of land type, land tenure, irrigation, availability of agricultural inputs and resource people or organizations. Considering these factors, programme implementation, extension strategies and priority agricultural practices need to differ from area to area.

Another difficulty concerns access to services. Farmers generate knowledge through experimentation, observation and sharing, but they still need access to extension services, research organizations and markets to get the most out of their learning. There are a number of constraints that make these services inaccessible to farmers. Sometimes these are a matter of psychology. Poor and marginal farmers often lack confidence to meet 'professionals' and ask them questions. Most farmers are barely literate and rely on somebody else to read for them. Sometimes the constraints are geographical. Research centres are often distant from farmers not only in physical terms, but also in the way they present research materials, subjects and results. Such limitations need to be tackled and overcome.

While implementation of the rice programme is proceeding very well overall, there remain many other challenges. Establishing equal working and learning opportunities for men and women is one such major challenge in Bangladesh. Another challenge has to do with the way we measure success. Organizations are under pressure from government or donor agencies to demonstrate quantifiable outputs. This can impinge upon the quality of the service provided as well as on the principle of putting farmers at the centre. For example, a programme may have contractual responsibilities with donors to train a certain number of farmers annually in order to justify budget allocations. If the number is overestimated, the rush to reach this number before the end of the year will decrease the quality of the work and the sustainability of the learning process. The organization needs to protect the quality of its interventions by avoiding an excessive preoccupation with target numbers.

Conclusions

The rice programme is still learning from ongoing activities and innovations. It strives to be an education programme rather than just agricultural extension. Clearly, it has been quite successful in facilitating a process in which farmers can get more out of their rice fields. To what degree this is due to their increased capacity in decision making and management is not yet clear. It is clear, however, that it represents an improvement over the training-lecture types of programmes whose limitations are well known in terms of their doubtful sustainability, dubious quality and poor fit with farmers' needs.

The programme needs to continue to focus on giving farmers opportunities to take control of their own learning. The social, economic and cultural milieu in Bangladesh does not easily support this. To start working with poor and marginal farmers, it has been necessary to adopt specific and beneficial sustainable agriculture entry points that offer a high likelihood of success. But the programme must ensure that these remain entry points and not sole objectives. In any event, the high adoption rates and the increased returns from the innovations brought about by the programme attest to the appropriateness of the intervention. Longer-term impacts beyond the adoption of particular sustainable agriculture practices may be taking place but still remain to be measured.

Notes

1 The growers surveyed owned, on average, 0.45ha of land. Note: Through the 1999 Bellagio conference, CARE/Bangladesh learned about the system of rice intensification. Farmer field school participants using the System of Rice Intensification (SRI) methods in Kishoreganj district in 2000 averaged 6.5t/ha. Farmers cooperating with the Department of Agricultural Extension in Kishoreganj averaged 7.5t/ha with SRI methods.

2 48 takas = US$1. One kilo of rice (paddy) is worth 5–7 takas (US$0.10–0.14).

3 These data are from the NOPEST mid-term review and monitoring report.

4 In compiling results, the areas considered were ones with no climatic disasters during the three seasons.

5 Since a large part of the fish production is consumed by the household, potential net return – defined as the value of the harvest minus the cost of producing it – is used rather than actual net return.

6 As with fish, most vegetables are consumed, so potential net return – the value of the harvest minus the cost of producing it – is also used here.

7 Caring for seed is traditionally a woman's responsibility.

New Meanings for Old Knowledge: The People's Biodiversity Registers Programme

Madhav Gadgil, P. R. Seshagiri Rao, G. Utkarsh, P. Pramod, Ashwini Chhatre, and Members of the People's Biodiversity Initiative

Introduction

All knowledge and wisdom ultimately flow from practices, but their organization differs among the different streams of knowledge. Folk knowledge is maintained, transmitted and augmented almost entirely in the course of applying it in practice; it lacks a formal, institutionalized process for handling. Folk ecological knowledge and wisdom are therefore highly sensitive to changing relationships between people and their ecological resource base. Today, both are eroding at a fast pace for two reasons: firstly, people now have access to newer resources such as modern medicines and are no longer as dependent on local medicinal plants and animals as before; and secondly, people are increasingly losing control over the local resource base, with takeovers by state and corporate interests (Gadgil and Berkes, 1991). However, folk knowledge and wisdom, with their detailed locality – and time-specific content – are of value in many contexts. They must therefore be supported in two ways: by creating more formal institutions for their maintenance and, most importantly, by creating new contexts for their continued practice (Gadgil et al, 1993). The programme of 'People's Biodiversity Registers' (PBR) is such an attempt.

It is a programme of documenting how lay people, primarily rural and forest-dwelling communities, understand living organisms and their ecological setting. The information recorded relates to present status as well as changes over recent

years in distribution and abundance; factors affecting distribution and abundance, including habitat transformations and harvests; known uses; and economic transactions involving these organisms. The document also records the perceptions of local people about ongoing ecological changes, their own development aspirations, and their preferences as to how they would like the living resources and habitats to be managed. We summarize here our experience of developing the concept and organizing the preparation of 52 such PBRs in different parts of India, the resultant understanding, and the interest that this programme has generated (Gadgil et al, 1998).

We believe that the PBR process, involving a collaboration between people working in the organized sector (e.g. educational institutions, government agencies and NGOs) and the practical ecologists, peasants, herders, fishers and traditional healers (all in the unorganized sector), is as significant as the product: the recorded information. A subset of the information collected, especially that pertaining to medicinal and other economic uses, has been recorded by ethnobiologists working in academic institutions and for the pharmaceutical industry and other commercial interests (Reid et al, 1993; Martin, 1995). In this process, however, the local people are treated as anonymous informants; they receive no particular credit for their knowledge, and the information is accumulated with little reference to particular localities and times (Posey and Dutfield, 1996). The PBR process, on the other hand, aims to record the information with full acknowledgment of the source; it thereby serves as a possible means of sharing of benefits that may flow from further economic utilization of such information. Another subset of the information recorded in PBRs is collected during 'Participatory Rural Appraisal' (PRA) exercises (Chambers, 1992, 1993) that feed into decentralized development planning. Generating good information for such participatory development is also an objective of PBRs; the PBRs differ from PRAs in their greater emphasis on recording all pertinent knowledge, including changes over the recent past, and in giving specific credit for the information collected. Although we have so far completed only one round of PBRs in any one locality, we expect it eventually to become an ongoing process of monitoring ecological change and generating the necessary information for locally adaptive management of living resources.

Materials and Methods

The People's Biodiversity Register Programme was initiated by the Foundation for Revitalization of Local Health Traditions as a programme focused on documenting community-based knowledge of medicinal plants and their uses, through a workshop held at the Indian Institute of Science, Bangalore in April, 1995 (Gadgil et al, 1996). Workers from voluntary agencies participating in this workshop went on to compile, by mid-1996, what were termed Community Biodiversity Registers at 24 sites distributed over ten states of India. This experience suggested that it would be desirable to broaden the scope of the exercise to all elements of biodiversity, and to record knowledge and perceptions at all levels, from individuals, households and ethnic groups to multi-ethnic communities. Thus, the name of the programme was modified to People's Biodiversity Register. A second workshop to explore this broader approach was organized at Supegaon in Maharashtra in August, 1995. This was followed by initiation of PBR activities at ten sites in four states of the Western Ghats region, as a part of the Western Ghats Biodiversity Network Programme (Gadgil, 1996). These experiences laid the foundation of the current set of PBR preparation at 52 sites in eight states as a part of the Biodiversity Conservation Prioritization Programme of the World Wide Fund for Nature – India (Gadgil et al, 1998). The focus of this programme is on the conservation priorities and preferred strategies of the local people. The account that follows primarily refers to the third phase.

This programme was initiated through a workshop held in March, 1996 at the Indian Institute of Science, Bangalore, involving potential collaborators from the states of Himachal Pradesh, Rajasthan, Bihar, Assam, Orissa, Karnataka, Maharashtra and the Union Territory of Andaman and Nicobar Islands. These eight regions were selected to provide a good sample of the varied ecological and social regimes of the subcontinent. Discussions at this workshop permitted a crystallization of the methodology and drafting of a methodology manual termed Srishtigyan (Hindi: Srishti, nature; Gyan, knowledge). There followed a series of further training programmes and workshops that have facilitated the fieldwork spread over 52 sites throughout the subcontinent, employing a common methodology. The first task of the state-level coordinators was to select the individual study sites that would represent the entire spectrum of ecological and social regimes within the state (Figure 10.1 and Table 10.1). The 52 study localities cover all of the bioclimatic zones of the country (Gadgil and Meher-Homji, 1990): tropical wet (18 sites), tropical moist (16), tropical dry (6), tropical semi-arid (4), sub-tropical (4), temperate (3) and alpine (1). They also cover a whole range of ecosystem types: forest (30), pastures (8), wetlands (14), degraded forests (3), agriculture (33), horticulture (8) and deserts (3). Sixteen of the study areas are protected: six national parks and ten wildlife sanctuaries, three of which are tiger reserves and two are bird sanctuaries.

After study areas were selected, field investigators were chosen from among college – or university-level science teachers or workers of rural development or environment-oriented NGOs. Many of these people are from nearby localities, and have considerable previous familiarity with the study sites. The field investigating teams worked closely with, and often included, some of the local residents. Of the 52 principal investigators of the programme, 14 were college teachers, two university teachers and two school teachers. There were four government officials, 13 NGO workers and six individuals engaged in development activities on their own. The entire programme engaged 350 researchers from all of these sectors and 200 assistants from village communities. As many as 1000 villagers had extensive involvement in the programme as local knowledgeable individuals.

The methodology of field investigations included the following components: building rapport with local people, clarifying project rationale and obtaining local

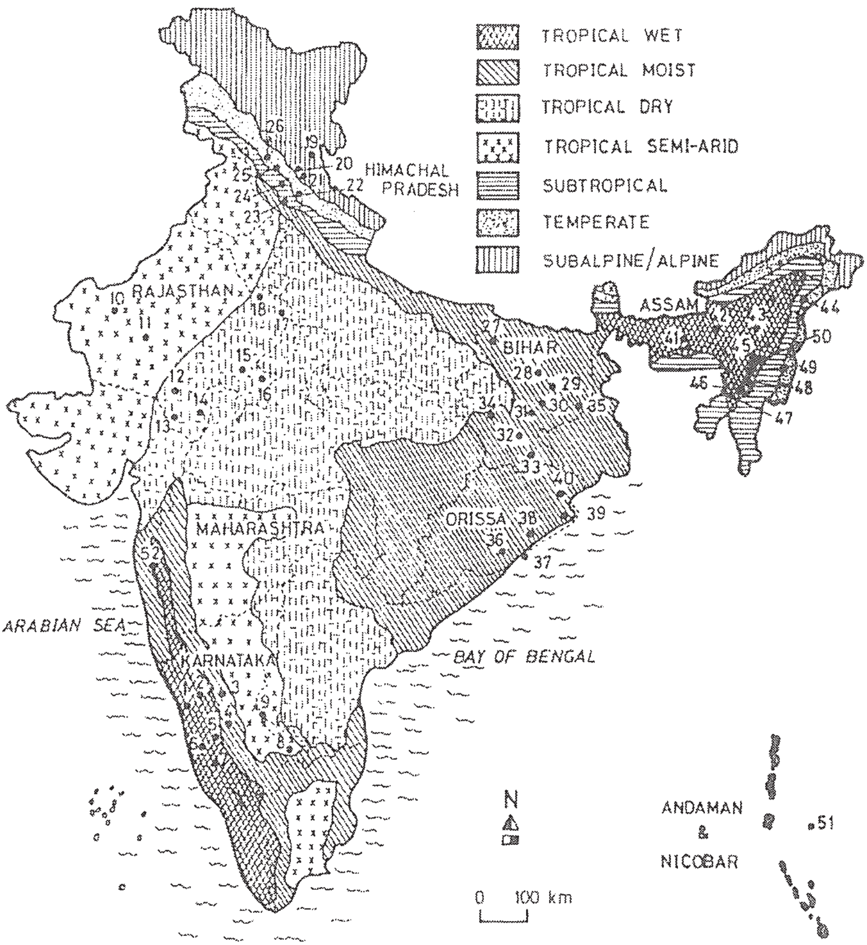

Figure 10.1 *041 Distribution of study sites across various bioclimatic zones in India. Site numbers refer to those in Table 10.1*

approval for the joint studies, identifying different biodiversity user groups, identifying individuals knowledgeable in different aspects of distribution and uses of biodiversity, interviewing individuals and groups with members representing different user groups, mapping the study site landscape, visiting representative elements of this landscape with some user-group members and knowledgeable individuals, and discussing resource use at the study area with the entire village assembly and with outsiders such as nomadic shepherds or artisans, traders and government officials. This methodology is spelled out in detail in the Srishtigyan manual (Chhatre et al, 1998).

Results

Living resources

Many widespread trends are evident in the 52 PBRs representing the entire spectrum of ecoclimatic and socioeconomic conditions of this diverse country. Agricultural production, especially of cereal grains, has increased over India as a whole, as has the production of wood from eucalyptus, poplar and *Acacia auriculiformis* plantations. Fish and shrimp production has also increased under aquaculture. These increases result from intensification of inputs and management. Outside such managed ecosystems, however, there has been widespread decline in both productivity and diversity of living resources. Such decline can be traced to a variety of factors: breakdown of social regulation of harvesting regimes; escalation in demand, well beyond the productive capacity of the resources, for meeting subsistence and market demands; deterioration in the productive capacity of resources attributed to adverse environmental changes such as pollution and siltation; and diversion of the land to other purposes such as mining and road construction.

We may cite here two examples of the breakdown in social regulation, one related to a breakdown of community-level understanding, and the other to a breakdown of localized authority. First, along several streams in the mountainous state of Himachal Pradesh, people used to observe a system of sacred pools called machiyals, where no fishing was permitted. This system of refugia promoted long-term persistence of fish populations fished elsewhere along the stream (Gokhale et al, 1998). Establishment of road communications has now rendered many parts of the state accessible to outsiders, such as military personnel who do not respect the protection to the machiyals. Simultaneously, road construction activity has led to widespread availability of dynamite, which is used for highly destructive fishing by such outsiders. This has led to considerable depletion of fish populations along these streams.

The second example comes from the semi-arid and arid state of Rajasthan, where extensive areas adjacent to villages were protected as sacred groves or orans, subject to highly regulated harvests, primarily of dead wood and fodder. These regulations were enforced by the village landlord families, mostly belonging to the dominant Rajput castes, until the land reforms around 1970. The orans were taken over as government property during land reforms. However, the government machinery did not act as an effective regulatory authority, so that most orans have become open-access resources subject to unregulated harvests, except for special cases such as Doli, which will be discussed.

Examples of excessive levels of harvests depleting already dwindling living resources of the public lands are part of every one of the PBRs. Resources so depleted include fuelwood, grazing, small timber for house construction, grass and palm leaves for thatching roofs, and medicinal plants. One village in Rajasthan was earlier named Vaidyonki Devli, Devli village of medicine men. With the depletion of all natural vegetation, including the medicinal plant resources, the villagers have removed the epithet Vaidyonki from the village name. The state of Himachal Pradesh has also witnessed a rapid depletion of medicinal plant resources with the manifold increase in commercial demand, for instance, for leaves of *Taxus buccata*, now known to contain an anti-cancer compound.

Living resources have declined through pollution. For example, several villages in Himachal Pradesh report the loss of honeybees, important for crop pollination, due to pesticide use. Fish populations of the large water body of Sone Beel in the Barak Valley of Assam have reportedly declined due to siltation following construction of a dam. Habitat change is another significant factor. In the village of Holanagadde in Karnataka, medicinal plant resources declined when the natural scrub created by lopping for fuelwood was replaced by an *Acacia auriculiformis* plantation.

The governmental agencies that control the public land and water resources more and more tightly have responded to this erosion of living resources by further restricting people's access without being equally effective in restricting the access of well-organized commercial interests. Thus, access to the Bharatpur National Park by Aghapur villagers has been strongly restricted, whereas the Darlaghat Wildlife

Sanctuary in Himachal Pradesh was delisted to facilitate the creation of cement plants.

Our PBRs do not, however, merely record instances of the degradation of living resources of public lands and waters. Two of the PBRs, pertaining to Doli village in Rajasthan and Dhani village in Orissa, record examples of the spontaneous establishment of regimes of regulated use, leading to resource recovery. The restrictions in Doli are the result of religious sentiments of a Hindu sect, the Bishnois, whose precepts call for protection of several species of plants and animals. At their instance, the local sacred grove (oran) has been well protected over the last 25 years (Gokhale et al, 1998). In the primarily tribal village of Dhani, the people on their own initiative have established a forest protection committee and have ensured excellent natural regeneration of the forest. We will discuss the Dhani experience further.

Practical ecological knowledge

People's dependence on living resources has declined along with the decline in ready availability of such resources to them. At the same time, people have access to new resources that can substitute, for example, allopathic drugs in place of herbal remedies, tiles in place of thatching for roof, or synthetic dyes in place of vegetable dyes. This has led to a decline in interest, among the younger generation, in the knowledge of living resources, a decline reinforced by the modern, largely bookish system of education. Our PBR studies reflect such decline in knowledge. In Kaihad village in Himachal Pradesh, residents as a whole know of ~ 450 species of plants and animals. However, while those 50 years or older can identify ~ 70 per cent of local flowering plants, characterize 40 per cent and mention uses for 5 per cent, the respective percentages decline to 25 per cent, 4 per cent and 1 per cent among people 30–50 years old, and to 0 per cent among younger people.

This is not universal, however. In predominantly fishing communities, such as Berhampur village near Chilika Lake in Orissa, much ecological knowledge persists among youth who continue to be engaged in fishing as a profession. Similarly, knowledge and use of medicinal plants is still common among all sections of the population, including the youth, in Mala village in Karnataka.

People affected

The starting point of the PBR exercise is to classify the concerned human population into 'user groups' on the basis of their relation to natural, particularly living, resources. Thus, cultivators owning sufficiently large tracts of land to fulfill their household biomass requirements may constitute one group; landless agricultural laborers dependent on public lands for their biomass requirements, such as fuelwood or dung, and on weaving baskets or mats for employment in the non-agricultural season, may constitute a second group, and specialist herders a third group. Within households, women assume greater responsibility for fuel and fodder collection than

Table 10.2 *Distribution of knowledge of a variety of specific uses of 173 plant species among different human communities of Shilimb village in Maharashtra State, India*

Kind of uses	*Communities*		*Katkaris*	*Dhangars*	*Brahmins*
	All 13	*At least 10*			
Human medicine	2	9	57	16	9
Veterinary medicine	1	1	1	3	1
Food	45	46	56	49	45
Fodder (cattle)	0	0	0	5	0
Fodder (sheep)	0	0	0	4	0
Agricultural implements	2	13	8	13	1
Ropes	3	4	4	4	4
Fuelwood	4	4	4	4	4
Fish poison	0	0	4	0	0
Other commercial uses	0	1	7	1	1

Note: Table entries are numbers of plant species.

men; hence, women from poor, landless families may constitute a distinct user group. PBRs show that greater dependence on living resources is also accompanied by much greater knowledge. For instance, in Shilimb village in Maharashtra, 13 distinct endogamous groups fall into five major user groups. Brahmins are substantial landowners and traders, Katkaris are landless agricultural labourers, Dhangars are specialist herders, and the other ten endogamous groups are divided into cultivators with medium-sized holdings and artisans. As Table 10.2 shows, Katkaris are by far more knowledgeable about uses of plant species. As may be expected, they are also reported to be the user group to suffer most from a degradation of the living resources of Shilimb. Similarly disadvantaged user groups are susceptible everywhere to suffering most from greater loss of access to public lands and water. For instance, similar groups in several PBR sites from Palamu National Park in Bihar are currently being asked to move out of their century-old settlement sites within forest areas.

Motivation

The PBR exercise involved recording the development aspirations of all of the different user groups at different sites. The citizens of India today uniformly equate development with higher incomes and upward social mobility. Everywhere, the wealthy and the powerful have better access to transport and communication, health care, education and water for household use and irrigation; all segments of society aspire for enhanced access to these resources as the core of development. In contrast, the people most dependent on and knowledgeable about biodiversity are, without exception, the poorest and least powerful. Better access to biodiversity resources and their conservation therefore tend to be viewed as (no doubt) desirable, but certainly not an integral component of development aspirations. Almost no segment of the rural population today is strongly motivated to organize and participate in efforts at conservation and sustainable use of biodiversity.

The PBRs also record the perceptions of the rural population about the current role and motivation of other major agents influencing the living resources, namely government agencies such as forest departments, and traders and industry. The government agencies are reported as being self-serving, corrupt and inefficient, the commercial interests as being motivated to pursue short-term profits. None of these agents is reported to be motivated to promote long-term conservation and sustainable-use objectives.

Resultant conflicts

PBRs document that almost all segments of the society in all study sites are committed to utilizing living resources in their own, often very divergent, short-term interests. This results in a variety of conflicts at many levels. A sample of conflicts recorded in the PBRs of Himachal Pradesh follows: (1) Within households, men and women differ on household use *vs* marketing of wood, and therefore in the choice of species to be planted on public lands. (2) Within a village, different user groups differ on the desirability of maintaining grazing lands for livestock *vs* planting these lands with trees that produce leaf fodder. (3) Within a village, the land-less households would like some of the public lands to be made available to them for cultivation, whereas landholding user groups would like them to be retained for fuelwood or fodder plantations or grazing lands. (4) There are conflicts among neighbouring villages on access to fuelwood and grazing and on the level of protection to be offered to plantations. (5) Villagers settled permanently on land come in conflict with nomadic herders on access to grazing and fodder. (6) Villagers come in conflict with traders in the collection of medicinal plants. (7) Villagers are in conflict with industry over the mining of limestone from forest lands traditionally managed by villagers. (8) Villagers are in conflict with the forest department over control of land earlier regarded as village common lands, over demands for compensation for damage to crops by wildlife and over management of village forest committees. (9) Villagers are also in conflict with the Public Works Department on damages suffered during road construction.

Lessons learned

PBRs include a discussion with the different user groups and with the village assembly as a whole on their prescriptions as to how the living resources should be managed. Although, as previously noted, the villagers do not include programmes for conservation and sustainable use of these resources as a part of their development aspirations, they uniformly note their unhappiness at the deterioration of this resource base. Their prescriptions for its good management overwhelmingly call for empowerment of local communities to play this role. They are, however, clear that local communities cannot on their own shoulder the responsibility; they need to be supported in many ways. Such support is needed to resolve conflicts within the village society, with neighbouring villages, and with commercial interests and the government agencies. All PBRs therefore suggest the institution of some form of co-management, cooperative arrangements among villagers, local educational institutions, NGOs and government agencies. There is considerable variation from user groups, from village to village and from one part of the country to the other, in the form of the suggested institutions.

Designing institutions

Given the broad consensus on the desirability of organizing community-based management systems, the various suggestions are best examined in the context of Ostrom's (1990, 1992) seven principles of design of long-enduring, self-organized systems. Clearly, it is not feasible to establish fully autonomous, self-organized systems on any widespread scale in the present-day Indian context (Gokhale et al, 1998). That is why the PBRs call for systems of co-management involving substantial support by government agencies to the community-based institutions as the appropriate arrangement (Gadgil and Rao, 1995). Ostrom's principles provide useful pointers to the most important areas in which local communities need to be supported by the state apparatus and other agencies, such as educational institutions and NGOs, to create viable decentralized institutions of management of natural resources.

Principle I – Boundaries of the managed resource should be well defined, and such a resource should be under the reasonably secure control of a well-defined human group.

At present, the living resources on public lands and waters are under the control of state agencies with boundaries defined by a system of land settlement as revenue lands, reserve forests, irrigation tanks and so on. However, the state agencies have a far from secure control over these resources, many of which are subject to abuse as open-access resources. In their stead, a new, decentralized system of governance called Panchayat Raj, with elected representatives from the level of village councils upward, is being put in place all over India (Singh, 1994). Many user groups support such an alternative arrangement; others express some doubts as to its efficacy. The unwillingness of government agencies to give up their own powers and to place resources under the secure control of Panchayat Raj institutions seems to be a major difficulty. Other problems arise in the case of fugitive resources, for example, river water affected by upstream influences such as water withdrawal or pollution. PBRs emphasize the need to set up proper machinery to resolve such cross-border conflicts.

Principle II – Groups responsible for resource management should be effectively organized.

Our PBRs record several misgivings about the efficacy of Panchayat Raj institutions to manage the living resources of public lands and waters. In part, these relate to the large number of people, in the order of 10,000, within the boundary of a panchayat. Self-organized management institutions are much more effective when they involve smaller, more homogeneous groups in face-to-face contact. Therefore, people in many of the study localities suggest that parallel committees representing smaller groups, working as subsidiary bodies of Panchayat Raj institutions, are more appropriate to take on tasks of natural resource management.

Principle III – Long-term benefits of conservation measures should be commensurate with the costs incurred.

Conservation measures entail certain restraints on the immediate use of resources, or on conversion of the land or water areas to alternative uses. These would imply certain opportunity costs. Conservation measures may also entail other costs such as crop depredation and killing of livestock or even of people by wild animals. These costs need to be effectively offset by benefits, which would generally be realized in the longer term. Furthermore, the costs would not be borne, nor would the benefits flow, equally to the different user groups. Management needs to be tailored to the time, locality and society-specific conditions. The PBRs bring this out well. For example, Himachal Pradesh sites might require rather special arrangements with nomadic herders who visit annually; these are irrelevant to other sites. Even with such flexible arrangements, the benefits may not be adequate to offset costs. Many PBRs therefore propose additional benefits, in the form of either social recognition or financial incentives. Thus, the village Doli in Rajasthan, which protects a large sacred grove with a substantial population of antelopes that inflict much damage on crops, may deserve payment of an annual service charge in recognition of its contribution to nature conservation. Such a service charge may take the form of a special annual grant by the Rajasthan State Government to the village council concerned.

Principle IV – Machinery enforcing the observance of management rules should be accountable to, and respected by, the actors.

Government agencies such as the Forest Department today are in charge of monitoring observance of resource use regulations, except in a few special cases such as the Doli village in Rajasthan. All of our PBRs suggest that this machinery is viewed to be self-serving, corrupt and inefficient, in no way accountable to people. Suggested alternatives include committees of local people working with a transparently functioning and people-oriented government machinery, assisted by local educational institutions and NGOs.

Principle V – Agreements should be arrived at on the basis of collective choice.

Currently, the resource use prescriptions are imposed from outside by a government apparatus that has no accountability towards local communities. All of our PBRs propose that this be replaced by a process in which the local community is actively involved in consultation with concerned government agencies and other actors such as educational institutions.

Principle VI – The management rules should be flexible.

Principle VII – Sanctions against those violating the rules should be imposed in a graduated fashion.

The centralized management agencies tend to impose uniform and rigid rules and sanctions against violations. All of our PBR exercises point to the need for flexibility and fine-tuning to the specific situation. An excellent example of this is provided by the working of the Forest Protection Committee formed at the initiative of people from a cluster of five villages around Dhani in Nayagarh district of Orissa. This management system was initiated in 1986 in response to extensive degradation of forest stock under government management. To begin with, the Forest Protection Committee banned all collection of forest produce, as well as grazing and encroachment for cultivation, in the 800ha plot. Initially, fines for violation were collected on the basis of the kind of produce extracted. After two years of strict protection, the forest began to regenerate and the Forest Protection Committee decided to permit extraction of leaves and fruits and grazing by livestock. After a further period of regeneration, there was further relaxation, permitting collection of fuelwood for household needs, but without any felling of green trees. At the same time, a few of the poorest families are now allowed to collect a limited quantity of fuelwood for sale as well.

Adaptive Co-management

The very broad consensus from our PBR exercises is the need to establish community-based systems of resource management supported by, and working in collaboration with, concerned governmental agencies, educational institutions and, where appropriate, NGOs. There is also a clear endorsement of the need for these management systems to be flexible and tailored to specific situations. Such systems may be termed as systems of adaptive co-management (Walters and Hilborn, 1976). The process of preparation of PBRs, as well as the product (the record created), emerge as very useful devices in such adaptive co-management systems (Anonymous, 1996). The value of the PBR process is exemplified by an experience in the village Nanj from the Karsog study area of Himachal Pradesh. The village was an active participant in the literacy movement during 1992–1993 and the people were exposed to a variety of issues relating to natural resource management. As a consequence, there was consensus to enclose a heavily degraded patch of forest. Regeneration on this patch has been extremely promising. During the literacy campaign, a blackboard was painted on a wall at a public place in the village for open classes and dissemination of information. Over the last few years, it had fallen into disuse, but it was revived during the PBR documentation to display the information collected, leading to public debates on the issues and, in turn, to conservation actions.

One such debate centred around the species kambal (*Rhus wallichi*, Hook, f.), a multi-purpose tree found up to the mid-Himalayas, considered to be a good source of fuelwood and green manure. It was pointed out, using the blackboard, that excessive pressure of both fuelwood and manure collection had reduced the kambal to a bush in the forest, leading to declining availability of both fuelwood and manure. After many days of discussion in front of the blackboard, it was decided that leaf manure for ginger was a higher priority. As other fuelwood species were available in the forest, it was agreed to restrict the extraction of kambal to leaves for green manure, with bushes pruned in such a way that one or two shoots would be permitted to grow. At the same time, a few progressive farmers decided to experiment with agricultural crop residues as a substitute for kambal leaves for manure. Over one year, they demonstrated that there was no difference in the yields from the two kinds of manure; subsequently, more farmers turned to crop residues as this meant lower labour inputs. As a consequence, kambal is now flourishing in the forest and through careful pruning and good rootsrock, it will grow back to tree size in a few years.

The documentation of natural resources, the history of their use, people's development aspirations, ongoing difficulties in resource management in the form of manifold conflicts, and people's prescriptions on how the resources should be managed are clearly very pertinent inputs for any system of adaptive co-management. The PBR of Berhampur village near Chilika in Orissa furnishes an interesting example of such a product. Chilika, the largest brackish-water lagoon in South and South East Asia, is under manifold threats. These arise because of the escalating pressures on natural resources: forests in the catchment that have been felled, surrounding fields that are sprayed with pesticides, or fish stocks that are caught in increasing numbers with mechanized boats and fine-meshed nylon nets. It is obviously impractical to think of going back to the old days when most resources were used far less intensively. However it is essential to manage the resources far more carefully.

In this, practical ecologists, such as the fisherfolk of Chilika, can provide valuable inputs, for they are the people with a serious long-term stake in the health of their environment. Table 10.3 summarizes the management prescriptions flowing from our PBR exercise in Berhampur village.

Benefit sharing

The PBR document could also serve a very useful function in implementing article 8(j) of the Convention on Biological Diversity (UNEP, 1992); this article calls for approval of local people in promoting wider use of their knowledge and sharing with them the benefits of such commercial utilization of knowledge. This is a difficult task, as some of this knowledge is already in the public domain, leaving no bargaining power with the providers. The remaining knowledge is variously distributed across communities and individuals, and is being actively tapped by the researchers and entrepreneurs, often violating the spirit of the CBD provisions (Volker, 1997). The issues may be illustrated by a concrete experience in the village Mala from Karnataka, notable for its continuing extensive use of herbal medicine. Mr. Kunjeera Moolya is the most knowledgeable of the dispensers of herbal medicines in Mala; he does not charge for his services, but makes a living as a farm

Table 10.3 *Conservation issues and measures identifies as possible solutions by fisherfolk of Chilika Lake in Orissa State, India*

Issues	*Measures*
Siltation	Dredging of inner and outer link channels. Soil conservation involving plantation and embankment.
Weeds	Increase in the salinity level of Chilika by opening the mouth and link channels. Biological control by introducing carps.
Water pollution	Limited use of motor boats. Ban on chemical food mainly used in prawn culture. Embankment around Chilika. Checking industrial pollution.
Prawn culture	Banning of spawn collection. Involvement of coast guards. Ecological training to the prawn culturists.
Increased fishing intensity	Alternative income sources for the locals. Revitalizing involvement of existing cooperative institutions. Check on the immigration of refugees. Check on the use of fine-mesh nets.
Encroachment	Survey and resettlement. Eviction of the encroachers. Restoring the traditional rights of the locals.

labourer. Moolya was approached in March 1995 by an agent of some pharmaceutical firm to disclose his knowledge of local medicinal plants. He went around the forest for two days and shared this information, for which he was paid a sum of Rs. 220 (US$6), equivalent to his normal earnings over four to five days. This agent evidently represented some pharmaceutical company engaged in screening Indian plant resources for possible commercial products.

The best organized of such programmes is run by Hoechst Marion Roussel India, a subsidiary of a multinational company of German origin (Volker, 1997). Hoechst runs a research unit in Mumbai, established in 1972 and described as a target-oriented lead discovery centre from natural origin. It employs some 70 PhD-holding scientists, all but the director being Indian citizens. Indigenous information, obtained from people like Moolya, as well as from published literature and modern electronic databases, is used to provide clues to rationalize the search for plants with interesting biological activities. The published literature includes that from the older tradition of Ayurveda and the modern tradition of ethnobotany. In neither of these traditions is there is any detailed, specific acknowledgment, at the level of local knowledgeable individuals, of the source of such information. Only three of the scientists employed by the Hoechst Research Centre are engaged in collecting samples of plants, fungi and microorganisms; others are busy with screening, toxicology and investigations of chemical modes of action.

Obviously, Hoechst would pay very many people like Moolya small sums like Rs. 220, and then pool together all the information generated with other public knowledge (such as of Ayurveda) and inputs from many scientific disciplines, to eventually develop a small number of products (Sukh Dev, 1997). The process may take many years, perhaps decades, and particular pieces of information provided by a specific individual may or may not yield any product. In any case, every product will use many other inputs in its development. It is therefore difficult to design a system of either regulating collection and use of such knowledge, or ensuring payment of royalty to a particular individual in case his/her knowledge provided an important clue. Furthermore, because much of such knowledge is part of shared cultural resources, there are questions of whether it is appropriate to reward any particular individual who may by chance have been the person to communicate a specific piece of information.

Given these complexities, our approach was to put on record only such information as was voluntarily disclosed by people without any persuasion on the part of investigators. Beyond this, other information was maintained off the formal record as claims, for example, that a particular person in village Kigga of Karnataka has an herbal remedy against snakebite. Such broad claims could subsequently be made public and may attract entrepreneurs to directly contact the claimants. The two parties may then negotiate terms under which the information may be revealed. Elsewhere in the world, innovative experiments of recording such exclusive, undisclosed information through various types of contracts are being initiated (Glowka, 1998). In Eucador, a project by the Inter-American Development Bank attempts to computerize traditional knowledge, segregated according to communities. The database manager, a local NGO, compares this with the public-domain knowledge listed in the NAPRALERT database housed at University of Chicago, Chicago, Illinois, USA. Knowledge not yet in the public domain is treated as trade secrets, and is transferred to potential users directly by the corresponding community or an intermediary, through agreements. Further, the NAPRALERT information that is unavailable to the people is also repatriated. On the other hand, know-how licences are negotiated between Aguaruna people from Peru and Searle and Company, the pharmaceutical division of Monsanto, irrespective of whether or not the knowledge was in the public domain. The licence brings the Aguaruna collection fees, annual know-how licence fees and milestone payments as the research progresses. The Aguaruna are also trained locally and in the university, are kept informed of the research progress and retain all the rights to resources as well as the right to terminate the licence. The Costa Rica Biodiversity Act also proposes a national registry of traditional knowledge. However, this will be used only to deny intellectual property rights to innovations with similar applications (Dutfield G. personal communication). In this case, the incentive for the people to record their knowledge is not obvious.

Apart from such one-to-one deals involving intellectual property rights, PBRs may also serve as a tool of conserving and respecting folk knowledge and rewarding through a different route, namely a system of awards linked to the quality of documentation of knowledge through PBRs (Gadgil, 1997). The state, international agencies such as UNEP or UNESCO, or private foundations may come forward to periodically reward the communities, in terms of special development grants and social recognition for excellence in documenting such folk knowledge. This would help to conserve such knowledge through creation of more permanent records, as well as to encourage the younger generation to acquire and keep it alive (Anonymous, 1996).

Prospects

The experience of preparing these 52 PBRs has been most positive, with considerable enthusiasm generated among teachers and students in educational institutions, among NGO activists and among members of local communities. An account of the experience appeared in the Annual Survey of Environment for 1998 published by *Hindu*, one of the leading English-language newspapers of south India (Gadgil et al, 1998). A large number of people from all over India have expressed an interest in undertaking PBR exercises in their own area, as a result of this exposure. Similar interest has been expressed from Brazil and South Africa as well. More concretely, the government of India, in its draft biodiversity act (Anonymous, 1998) tabled in the parliament session during April 1999, has specifically entrusted to the village councils the responsibility of documenting biodiversity resources, knowledge, and conservation efforts. Further, the bill provides for direct sharing of royalties from the commercial application with the individual or group of people only if the exclusiveness of the knowledge or resources that they provided can be ascertained. In all other cases, part of the benefits generated from commercial application of biodiversity and related knowledge would be deposited in a national fund. This national fund would be used primarily for rewarding and encouraging conservation efforts and knowledge contributions. Although the bill does not specifically mention the village documents as the basis for benefit sharing, it would eventually become imperative for the government to do so. Interestingly enough, without waiting for the government initiative to take off, the NGO group that coordinated this exercise in the state of Himachal Pradesh is seriously pursuing a follow-up, with many more PBRs being prepared throughout the state, primarily as a tool for adaptive co-management. A similar effort is on in 60 panchayats in the district Ernakulam of Kerala. This would be part of the vigorous attempt to decentralize development planning in the state. Other NGO groups from Karnataka and Andhra Pradesh are also preparing PBRs in several villages, with the expectation that these would also serve to protect people's rights over resources and knowledge. We are attempting to computerize the information contained in PBRs and to develop systems of synthesizing this information at higher spatial scales, such as districts and states. Eventually, the relevant, spatially aggregated information can be fed back to people so that they can benefit from learning about uses, trade value or conservation efforts in other areas. In the long run, we have every hope that PBRs will evolve into a useful tool supporting a process of community-based management of living resources, contributing to conservation, and the rewarding of folk knowledge.

Acknowledgments

People's Biodiversity Registers has been an extensive, cooperative effort; we are therefore grateful for numerous contributions of a very large number of colleagues from academic institutions and NGOs, as well as among the residents of the 52 study sites. It is unfortunately not possible to name all of them individually. K. C. Malhotra, M. K. Prasad and Darshan Shankar have guided the whole exercise. Shekhar Singh, Ashish Kothari and Graham Dutfield provided useful suggestions. From the Western Ghats Biodiversity Network, Yogesh Gokhale, K. P. Achar, G. K. Bhat, Winfred Thomas, Parvati Menon, Dayanand Bhat, C. K. Poojari, Prakash Pandit and K. N. Deviprasad offered many insights. The state-level co-ordinators in the Biodiversity Conservation Prioritization Project, in particular, D. S. Srivastava, Ajay Mehta, P. C. Bhattacharji, Devashish Kar, Sameer Acharya and T. S. Channesh and their colleagues, furthered the process. Anirban Ganguly and Smita Botre shared their experiences. Deepak Jain helped with the data compilation. This work has been funded by a long-term grant to the Centre for Ecological Sciences, Indian Institute of Science from the Ministry of Environment and Forests, Government of India, by a Fellowship from the Pew Foundation, and by a grant from WWFIndia from the Biodiversity Support Programme, a USAID-funded consortium of WWF-USA, World Resources Institute (WRI) and the Nature Conservancy.

From Extension to Communication for Innovation

C. Leeuwis

Historical Roots and Evolving Conceptions of Extension

The meaning of the term 'extension' has evolved over time, and has different connotations in different countries. In this section we touch on such different conceptions.

Origins, early meanings and international terminology

Throughout history, and across the world, there have existed patterns of agricultural knowledge exchange, with some people (e.g. religious leaders, traders, elders etc.) often playing special 'advisory' roles in this respect. According to Jones and Garforth (1997), more or less institutionalized forms of agricultural extension existed already in ancient Mesopotamia, Egypt, Greece and Phoenicia. The term 'extension' itself is more recent; it orginates from academia, and its common use was first recorded in Britain in the 1840s, in the context of 'university extension' or 'extension of the university'. By the 1880s the work was being referred to as the 'extension movement'. In this movement the university extended its work beyond the campus. In a similar vein, the term 'extension education' has been used in the US since the early 1900s to indicate that the target group for university teaching should not be restricted to students on campus but should be extended to people living anywhere in the state. Here extension is seen as a form of adult education in which the teachers are staff members of the university.

Most English-speaking countries now use the American term 'extension'. In other languages different words exist to describe similar phenomena. The Dutch use the word *voorlichting*, which means 'lighting the pathway ahead to help people find their way'. Indonesia follows the Dutch example and speaks of lighting the way ahead with a torch (*penyuluhan*), whereas in Malaysia, where a very similar

Reprinted from Leeuwis C. 2004. From extension to communication for innovation. In *Communication for Rural Innovation.* Blackwell, Oxford, Chapter 2, pp22–38.

language is spoken, the English and American word for extension translates as *perkembangan*. The British and the Germans talk of *advisory work* or *Beratung*, which has connotations of an expert giving advice but leaving the final responsibility for selecting the way forward with the client. The Germans also use the word *Aufklärung* (enlightenment) in health education to highlight the importance of learning the values underlying good health, and to emphasize the need for arriving at more clarity on where to go. They also speak of *Erziehung* (education), as in the US where it is stressed that the goal of extension is to teach people to solve problems themselves. The Austrians speak of *Forderung* (furthering) meaning something like 'stimulating one to go in a desirable direction', which again is rather similar to the Korean term for 'rural guidance'. Finally, the French speak of *vulgarisation*, which stresses the need to simplify the message for the common man, while the Spanish sometimes use the word *capacitacion*, which indicates the intention to improve people's skills, although normally it is used to mean 'training'.

Evolving definitions

Enlightenment definitions of extension

Initial meanings of the term 'extension' – as well as international equivalents of the term – have been influenced significantly by 'enlightenment thinking'. Although different nuances exist, the basic thrust is that 'the common folk' are to a degree 'living in the dark', and that there is a need for well-educated people to 'shed some light' on their situation by means of educational activities. This reflects that the early conceptions of extension were somewhat paternalistic in nature; that is, the relationship between the extensionist and their clients was essentially looked at as being similar to the teacher/student or parent/child relationship, placing the extension agent in an 'expert' and 'sending' position and their audience in a 'receiving' and 'listening' role. In line with this tradition, many definitions of agricultural extension emphasize its *educational* dimensions:

> Extension is a service or system which assists farm people, through educational procedures, in improving farming methods and techniques, increasing production efficiency and income, bettering their levels of living, and lifting social and educational standards. (Maunder, 1973, p3)

> Extension is an ongoing process of getting useful information to people (the communicative dimension) and then assisting those people to acquire the necessary knowledge, skills and attitudes to utilise effectively this information and technology (the educational dimension). (Swanson and Claar, 1984, p1)

It must be noted that each definition is a product of its time. When 'enlightenment' conceptions of extension were formulated there was still a firm belief in the potential and blessings of science as an engine for modernization and development, and there was a genuine concern that everybody should be able to pick the fruits of science. The belief then was that by adopting science-based innovations, and by grounding their practices and decisions in rational scientific insight and procedures, farmers and agriculture would benefit almost automatically. In view of the experiences of the last decades, however, science has nowadays become much more contested and the belief in science as a neutral and objective engine to progress has eroded significantly (Knorr-Cetina, 1981; Callon et al, 1986; Van der Ploeg, 1987; Beck, 1992). Although science has contributed significantly to agricultural change and production increases in high potential areas, its impact in other regions has remained much more limited. Moreover, science-based agriculture in high potential areas was accompanied by a number of serious problems related to, among other topics, the environment and health. Furthermore, even in high potential areas scientists regularly produced innovations and recommendations that were of limited use to many farmers. It was realized that successful innovation required as much input from farmers themselves as from scientists.

In line with 'enlightenment' thinking, there was great concern in the 1950 to 1970 period with the 'adoption and diffusion' of science-based innovations. Extension scientists developed an interest in so-called adoption *decisions*. In the context of diffusion, it was also recognized that farmers could gain a lot from each other's knowledge and experience (regarding new technologies, among other topics) when solving agricultural problems (Van den Ban, 1963). Inspired by such interests and insights, the emphasis in definitions of extension shifted slightly from 'education' to supporting *decision making* and/or *problem solving*:

> Agricultural extension: Assistance to farmers to help them to identify and analyse their production problems and to become aware of the opportunities for improvement. (Adams, 1982, pxi)

> Extension is a deliberate and systematic attempt – by means of the transfer of knowledge and insight – to help and/or develop someone in such a way that the person is able take decisions in a specific situation with a maximum level of independence, consciousness, and conformity with his own interest and well-being. (Van Gent and Katus, 1980, p9, translated by the authors)

> Extension involves the conscious use of communication of information to help people form sound opinions and make good decisions. Van den Ban and Hawkins, 1996, p9)

The last definition is the one which was used in the predecessor of this book (Van den Ban and Hawkins, 1996). Like most definitions presented so far, it still carries the idea that extension is mainly about 'help' in the interest of the farmer.

Intervention definitions of extension

The definitions mentioned so far are in essence *normative* definitions, in that they indicate what the authors feel extension *should* be and/or *should do*. In other words, they 'prescribe' what the authors *would like* extension to look like ideally, e.g. as a practice that is experienced as 'help' and 'assistance' and leads to 'good decisions' and 'development'. Alternatively, one could also try to define extension more descriptively in terms of what people who call themselves extensionists *actually do*, which frequently might not correspond with normative definitions (see also Röling and Kuiper, 1994). When taking a closer look at what extensionists do in practice, one might, for example, discover in some cases that their work has little to do with 'help' but rather with imposing technologies and/or enhancing state control over farmers (e.g. Ferguson, 1990). Along these lines, it was recognized during the 1980s that extension could not just be regarded as 'help' and 'being in the interest of the recipient'. It was realized that extension is in many ways also an *intervention* that is undertaken and/or paid for by a party who wants to influence people in a particular manner, in line with certain policy objectives. Thus, it was realized that there was often a tension between the interest of the extension organization (and/or its funding agency) and the interest of recipients such as farmers. Government extension services could, for example, aim at increasing the production of export crops, while farmers would be more interested in other issues or crops. In this more descriptive conception of extension, there needed at least to be a partial *overlap* or *link* (see Röling, 1988) between the interests of clients and extension organizations, otherwise people would obviously not be willing to change (unless they were forced/persuaded to by other means than just extension messages). In line with such views new definitions of extension emerged:

> Extension is helping behaviour consisting of – or preceding – the transfer of information, usually with the explicit intention of changing mentality and behaviour in a direction that has been formulated in a wider policy context. (Van Woerkum, 1982, p39, translated by the authors)

> Extension is a professional communication intervention deployed by an institution to induce change in a voluntary behaviour with a presumed public or collective utility. (Röling, 1988, p49)

The phrase added by Röling on 'presumed public or collective utility' is important, because it was used to distinguish extension from other forms of communication – intervention such as:

- *Commercial advertising*, where the goal is to sell products in the interest of a limited group (salesmen, shareholders).
- *Political propaganda*, where the goal is to influence people's ideological beliefs and/or perceptions of reality in order for some to gain or maintain power.
- *Public relations*, where the goal is to manage one's own reputation or public image.

At the same time, this phrase exemplifies that these definitions still contain normative elements. After all, it is more or less implicit in Röling's definition that extensionists should not be involved in, for example, trade, advertising or political propaganda, and if they are this cannot be regarded as 'extension'. As Röling and Kuiper (1994) point out, it is impossible to avoid normative elements in a definition of extension if one's purpose is not only to study extension as a societal phenomenon, but also to inform extension practitioners on how they can do better. From a purely descriptive point of view, the definition of extension would be something like:

> Extension is everything that people who think of themselves as extensionists do as part of their professional practice.

A book written on the basis of such a definition of extension could reveal very interesting activities and phenomena, but as soon as one wants to draw lessons for a wider audience one needs to assume certain criteria as to what it is, and is not, that extension aspires to, and how.

Extension as communication for innovation

The two 'intervention' definitions of extension still start largely from the premise that extension derives from a semi-state institution that is concerned with the public interest or public policy. This situation is rapidly changing in view of the emergence of private and NGO-based extension and communicative intervention. In addition, we need various changes in the definition of extension if we are to take the challenges seriously. These include a need to:

- Shift away from a focus on *individual* behaviour change which has characterized most of the definitions so far, and incorporate the idea that extension is about fostering new patterns of coordination.
- Move away from the idea that extension works mainly on the basis of *predefined* directions, policies and innovations, and emphasize its *generative* dimensions.
- Indicate that changes usually have a dual (material-technical and social-organizational) component.
- Transcend the idea that extension is mainly concerned with decision making, and emphasize the importance of *social learning* and *negotiation* in extension processes.
- Define extension as a *two-way* or *multiple-way* process, in which several parties can be expected to contribute relevant insights, and which may have action implications for all parties (not only farmers, but also researchers, extensionists, policy makers, agricultural industries etc.) involved in the process.

In view of such significant needs for redefinition (see also Sulaiman and Hall, 2002), some senior authors in the field of extension have chosen to completely *abandon* the notion of 'extension' altogether (e.g. Röling and Wagemakers, 1998; Van Woerkum et al, 1999; Ison and Russell, 2000). They feel that the word 'extension' has misleading connotations, and that it is practically impossible to stretch the meaning of the concept as necessary. In line with this, Van Woerkum and

Röling no longer use the concept in many of their writings, and they have in their university renamed the field of Extension Science as Communication and Innovation Studies. Similarly, Ison and Russell (2000) speak of 'second-order research and development'. In many ways we agree with such proposals to move away from the term 'extension'. The main reason why we still use the term is that this text is aimed not just at a small group of academics, but also at a wider group of practitioners in training and management positions of which many still identify strongly with the term 'extension'. However, this group is likely to erode, while alternative audiences who do similar work are likely to expand. Hence, we have chosen to start with the term 'extension' and emphasize the need to change our conception of it. In view of the above, we propose to define extension as:

> a series of professional communicative interventions amid related interactions that is meant, among others, to develop and/or induce novel patterns of coordination and adjustment between people, technical devices and natural phenomena, in a direction that supposedly helps to resolve problematic situations, which may be defined differently by different actors involved.

Or in a more condensed form:

> a series of embedded communicative interventions that are meant, among others, to develop and/or induce innovations which supposedly help to resolve (usually multi-actor) problematic situations.

Let us look more closely at some of the ingredients of this, mainly descriptive, definition:

1 The definition maintains that extension is a *professional* activity, practised by people who are somehow paid and/or rewarded for it. We do not call everyday communicative interactions, for example, between farmers, 'extension', even if they contribute to innovation.
2 Extension is regarded as an *intervention*, as it is usually subsidized or paid for by external agencies (donors, governments, private companies) whose aspirations for doing so are not the same as those of the supposed beneficiaries. Nevertheless, extension can only be effective if there is sufficient overlap or compatibility between the aspirations of change agents and clients.
3 Extension draws heavily on *communication* as a strategy for furthering aspirations. Communication is the process through which people exchange meanings (e.g. through the use of information). Thus, extension is an activity that is geared towards bringing about *cognitive* changes, used as a trigger for other forms of change (e.g. human practices, growth of crops, water availability, regulations). At the same time, the emphasis on 'communication' marks a shift away from a focus on *education* to a focus on *learning*.
4 Extension is a *process* involving a *series* of communicative interventions and interactions. It is not a once-only event. People respond to communicative

interventions, and such interventions have consequences, which usually bring about other communicative interventions.

5 Extension takes place *amid other interactions*, which indicates that there are many other interactions going on between people that do not involve extension and/or change agents, but which are still very relevant to the process. Farmers in a village, for example, interact a lot with each other, with other service providers and with community and/or religious leaders, and this is bound to have an impact on innovation processes.

6 Although communication workers are usually interested, albeit with different degrees of intensity, in bringing about change and innovation of some kind, we cannot explain the dynamics of the process by just looking at such intentions. Whenever people interact, multiple goals and intentions play a role. Change agents too may have *other aspirations*, some very mundane, that impinge on the way they go about their work; these may include pleasing their boss, aquiring social status, enhancing control over farmers, reserving time for side-line activities, visiting home regularly etc.

7 The statement that extension aims to '*develop and/or induce*' innovation emphasizes that we cannot simply look at extension as 'dissemination of innovations'. Frequently, extension activities are, or need to be, geared towards designing new innovations. And even if extension activities aim at the 'diffusion' of existing innovation packages, this can often not be effective without including elements of 'redesign'. The term 'to induce' is chosen here to capture this mixture of dissemination and adaptation. The definition does not further specify what *kind* of processes are involved in 'developing' and 'inducing', thus leaving space for all sorts of social processes, including social learning, network building, decision-making, negotiation and human capacity building.

8 The '*innovations*' that extension seeks to contribute to are regarded as '*novel patterns of co-ordination and adjustment between people, technical devices and natural phenomena*'. The latter phrase is used to convey that effective innovations – especially in the field of agriculture and resource management – include a balanced mixture of social, technical and natural elements and processes.

9 Extension activities are usually legitimized by referring to the need for solving a *problematic situation*. Whether or not this problematic situation is resolved, and to what extent, is of course something that remains to be seen as the process unfolds. Hence, the use of the term '*supposedly*' in the definition.

10 The term '*supposedly*' is used to point to a different issue as well. Although in an extension process solutions and innovations are often *presented* as contributing to problem solving, this does not mean that they are promoted by extensionists or others solely or mainly for this purpose. In an extension process, change agents may have various aspirations (see also point 6). Thus they may, for example, induce Integrated Pest Management innovations mainly in order to improve their own experience and job opportunities.

11 Finally, the definition mentions '*multi-actor problematic situations*' (rather than of problem situations) in order to indicate that the solving of such situations

> usually depends on the activities of several interconnected actors, who may in fact have different views of what the problem is, and what criteria the solution should meet. Even in situations where an individual farmer raises a seemingly individual problem, there are usually more people involved (e.g. other household members, family, labourers, contractors), who are part of the problem or its solution. For a male farmer, the cost of pest infestation may be a problem because it reduces cash income available for socializing in a bar, while his wife may regard it as a problem because it prevents her from buying school uniforms. Thus, the availability of male and female labour for labour intensive pest management strategies may depend on an agreement on the distribution of the extra cost incurred. Similarly, the feasibility of adopting a disease resistant crop variety – which also happens to be early ripening – may depend on the willingness of others to provide labour at an earlier time in the season.

As can be seen from these discussions, we have tried to arrive at a mainly *descriptive* definition of extension. This is because one cannot hope to contribute to extension without describing what it entails in practice. At the same time, however, it is impossible to make practical contributions without a vision of how it can be done better. Thus, points 3 and 7 are more normative in nature as they indicate what we feel extension *should* do, even if we know that change agents often also use non-communicative strategies to promote change (which contradicts with point 3), and still regard and organize their work largely as 'dissemination' (which is at odds with point 7). We are aware that the descriptive ingredients of the definition in particular may raise additional normative issues for the reader, for example on whether or not we can accept that change agents go against the interests of certain clients, have hidden agendas, personal goals etc.

Terminology from this point onwards

In the preceding sections we have described how the concept of 'extension' has evolved historically, and emphasized the need for a novel definition. Essentially, we intend to look at extension as 'communication for innovation'. From here on we use the latter term whenever possible, or use the term communicative intervention. Similarly, we minimize the use of the terms 'extensionist' and 'extension worker', and – following Van Woerkum et al, 1999 – write of communication specialists, communication workers or change agents instead.

Different Types of Communication Services and Strategies

In practice, communication for innovation can take many forms, not just in terms of the methods and techniques used, but also with regard to the *wider intervention purpose*, which again relates closely to the *assumed nature of the problematic situation*. Depending on the situation, the problem may, for example, be regarded as 'a lack of adequate technology', 'conflict over collective resources', 'lack of organizational capacity' or as 'an individual farm-management problem'. Clearly, the practice of communication for innovation (and the theories on which this is based) will have to differ accordingly. In Table 11.1 we have summarized several types of communicative intervention, which we will call different *communication services* (as a shorthand for 'communication for innovation' services), since they essentially define different kinds of '*products*' that can be 'delivered' by communication workers. At the same time, however, they can be seen as different *communication strategies* because they refer also to the *way in which* communicative intervention is supposed to contribute to societal problem solving. Depending on one's analysis of a problem, one may decide that providing a specific type of *service* is an appropriate *strategy* towards improving the situation.

The first two services in Table 11.1 we group together under the term 'farm management communication'. This involves modes of communicative intervention that are particularly geared towards supporting 'individual' farm households in identifying, interpreting and solving problems on their specific farms. Even if supporting horizontal knowledge exchange clearly involves working with farmer groups, the focus in both types of communicative intervention is on dealing with 'individual' farmers' problem situations ('individual' in quotes because different household members are often involved) which do not require collective action. That is, although farm households can assist each other in managing such issues by means of horizontal knowledge exchange, farm management communication focuses on problems for which the locus of control and responsibility lies with individual farm households, which can take action independently. In contrast, there are several other communication services which inherently require forms of coordination which transcend the household level (see Table 11.1).

Apart from these different communication services/strategies, there are also some general *communication functions* which may be relevant within *each* of the strategies described in Table 11.1. A function like 'information provision' (see Table 11.2), for example, can at some point be relevant to all strategies mentioned in Table 11.1. This implies that even if there are differences with regard to eventual intervention goals, and even if operational methods are likely to be different, there can also be considerable overlap regarding sub-goals and methods.

Together, these services/strategies and functions give an overview of the types of things that communication workers do, and for what purpose. All these services and functions can be performed in different ways, depending among other factors on whether one starts from an 'instrumental' or 'interactive' mindset.

Basic rationale of different communication services and strategies

Communication strategies differ not only in terms of their intervention purpose, but also with regard to the preferred role division between communication workers and clients. Similarly, each distinct strategy requires a different emphasis to the

Table 11.1 *Different communication for innovation services/strategies and their characteristics*

Strategy/service	*Intervention goal*	*Role of communication worker*	*Role of 'client(s)'*	*Key process(es) involved*	*Basis of legitimation*
Focus on 'individual' change/farm management communication					
Advisory communication	• Problem solving • Enhancing problem • Solving ability	• Consultant • Counsellor	• Active problem owner	• Problem solving • Counselling	• Active demand
Supporting horizontal knowledge exchange	• Knowledge exchange • Diffusion of innovations	• Source of experience • Facilitator	• Active learners/ sources of experience	• Learning • Networking • Problem solving	• Active demand • Public interest • Limited resources
Focus on collective change/coordinated action					
Generating (policy and/or technological) innovations	• Building coherent innovations	• Facilitator • Resource person • Supporting vertical knowledge exchange	• Active participants	• Problem solving • Social learning • Network building • Negotiation	• Societal problem solving • Ensuring progress • Qualities of interactive mode of working
Conflict management	• Managing • Pre-existing conflict	• Mediator • Facilitator	• Stakeholder participant	• Negotiation • Social learning	• Wish to remove obstacles to progress
Supporting organization development and capacity building	• Strengthening the position of a group or organization	• Organizer • Trainer • Facilitator	• Active participants	• Social learning • Negotiation	• 'Political' sympathy with a group
Focus can be individual or collective change					
Persuasive transfer of (policy and/or technological) innovations	• Realization of given policy objectives • Predefined behaviour change	• Social engineer	• 'Unexpecting' receiver (initially)	• Adoption • Acceptance	• (Democratic) policy decision • Preceding interactive process

Table 11.2 *General communication functions which can be relevant within different communication services and strategies*

Function	*Intervention sub-goal*	*Role of communication worker*	*Role of 'client(s)'*
Raising awareness and consciousness of predefined issues	• Encouraging people to define a situation as problematic • Mobilizing interest	• Providing (confrontational) feedback • Raising questions	• Unexpecting receiver or relatively passive participant
Exploring views and issues	• Identifying relevant views and issues	• Stimulating people to talk • Active listening • Active learning	• Source of information • Active participant/ learner
Information provision	• Making information accessible to those who search for it	• Translating and structuring information	• Active learner
Training	• Transferring and/or fostering particular knowledge, skills and abilities	• Educator/trainer	• Student

key processes that change agents may usefully support during the interaction. Finally, the grounds on which such services/strategies are, or can be, deemed socially acceptable, desirable and/or legitimate can diverge. It is important that organizations for communicative intervention have a clear idea of the types of services they wish to provide, as it has important implications for the training of staff, recruitment policy, organizational management etc. Below we will outline the basic rationale behind the different communication strategies indicated in Table 11.1.

Advisory communication

Advisory communication happens when farmers ask communication workers to share their ideas on how to deal with a particular management problem. These problems can be immediate and operational (e.g. 'how to fight the disease I discovered yesterday'), or have a longer timescale (e.g. 'what crops can I grow best next year'; 'should I continue farming in the long run'). In helping farmers to deal with such problems, communication workers may not only provide relevant substantive knowledge, but can also offer guidance on the process of problem solving, or can enhance the clients' own problem-solving ability. It can be important to help farmers become more aware of what their goals and aspirations are in the first place (Zuurbier, 1984), so that they can define more clearly what is problematic and what is not.

In principle, the initiative for advisory communication lies largely with the farmer. Of course, communication workers can 'advertise' that they are able to help solve particular types of problems, but it is essentially up to the farmer whether to use such services. It is this active or expected demand by clients that is often used to legitimize the provision of this kind of communication service. In advisory communication, the communication worker's role is basically that of a consultant or counsellor, depending on whether the emphasis is on providing knowledge or process guidance. For the adequate provision of these kinds of services, it is particularly important that communication workers have, or have access to, relevant kinds of expertise, and that they have adequate skills to elicit the needs and expectations of farmers, as well as the capacity to adjust to these.

Supporting horizontal knowledge exchange

Individual farmers usually have much expertise – based on experience, on-farm experimentation and/or training – which could be relevant to other farmers. Farmers are aware of this and as a result there are often informal means of farmer-to-farmer (i.e. horizontal) exchange of knowledge and information. Typically, markets, work parties, funerals, bars, celebrations, community meetings and church services provide opportunities for farmers to talk about agriculture, while observation of other farmers' practices is also an important mechanism for horizontal exchange. If needed, communication workers can stimulate or help to improve farmer-to-farmer exchange in various ways. They can, for example, organize meetings or festivities that are conducive to this kind of exchange, induce the formation of study groups, support existing groups and networks with training and logistics, develop more systematic modes of farm comparison, correct uneven exchange of knowledge within communities, communicate experiences from other communities, organize excursions etc. The role of the communication worker here is not that of a consultant or expert, but rather of a *facilitator*; that is, of someone who brings people together (networking) and acts as a catalyst for, and/or directs, learning and exchange processes, either in general or around a specific problem. Sometimes farmers actively demand these kinds of services, while in other cases governments support farmer-to-farmer exchange for the benefit of the public (e.g. more rapid diffusion of innovations). In addition, public extension organizations in particular often use farmer-to-farmer exchange to make efficient use of increasingly limited resources, i.e. to reach a relatively high number of farmers with limited inputs and/or to stimulate knowledge exchange in the absence of professional communication workers.

Generating policy and/or technological innovations

As indicated in the previous chapter, there is an increased need for communication workers to organize processes through which new innovations are designed, rather than to 'sell' predefined packages to farmers. 'Innovations' here are 'novel working wholes' (Roep, 2000) that involve a variety of practices and multiple actors. Often innovations have technological components, but some are more 'policy-oriented' such as novel market arrangements, new government regulations and/or alternative forms of organization. The main purpose of this type of communication service, then, is to arrive at appropriate and coherent innovations in the face of certain challenges and/or problems. Due to the collective nature of innovations, this communication service usually requires the bringing together of various stakeholders in group sessions and/or semi-permanent 'platforms' (Röling, 1994a). Here a wide range of activities can take place, including joint experimentation and exploration, aimed at generating new knowledge, insight and mutual understanding. In addition, forging effective links and knowledge exchange between such platforms and various knowledge institutions (e.g. applied research, universities etc.) can be an important stimulant to innovation. Again, the key function for communication workers here is to facilitate the process, and it is important to work towards a balance between new *technical* devices and novel *social-organizational* arrangements. Thus, besides learning-oriented activities such as experimentation and exploration, sufficient attention should be paid to the creation of support networks and the negotiation of new arrangements between various stakeholders. This often means that communication workers have to deal with tensions and conflicts that emerge during the innovation process. Investments in these kinds of innovation processes are often made because of specific societal problems and/or the desire to foster progress in areas where this is thought to be lacking. Moreover, this type of communicative intervention is inherently interactive (at least to some extent) and is frequently legitimized with reference to specific qualities attributed to an interactive mode of working.

Conflict management

In some situations, serious tensions and conflicts among stakeholders form the starting point for communicative interventions, rather than the intervention emerging during an interactive process (see above).[1] In many communities or regions conflicts exist around the distribution and use of collective resources (e.g. water, arable land, grazing land, fish etc.). Such conflicts often have cultural, ethnic, moral and/or political dimensions too. In some cases conflicts are productive in the sense that innovative solutions arise from the pressures and competition that accompany conflict. All too frequently, however, conflicts have negative consequences (e.g. natural resource degradation) and/or hinder progress and innovation; that is, in some cases it can be a long time before conflicts are resolved and/or become productive. Communication workers are often confronted with conflicts that affect their work and they can even become entangled in them. From the literature on conflict resolution (e.g. Pruitt and Carnevale, 1993), however, we know that the involvement of relative outsiders – in the form of mediators, facilitators or referees (e.g. judges) – may help to partly resolve conflict and/or to make conflicts productive. Thus, rather than becoming a party in the conflict, communication workers may at times be able to play a positive role in conflict management. Depending on the situation, this can be either by adopting a mediating or facilitating role, or by encouraging the handling of the conflict by others who are in a better position – in terms of status, skills and authority – to contribute positively. As Röling (1994a, 1994b) suggests, such efforts may take place on a 'platform' where different stakeholders are brought together to overlook the situation and learn and negotiate towards more productive outcomes (i.e. coordinated action). Although conflict management has not been a traditional extension service or strategy, we feel that 'new style' extension organizations may have to become better equipped for it. This is because innovation, conflict and intervention are closely intertwined, which essentially means that conflict management is something that change agents cannot run away from. Dealing with tension and conflict requires insights and skills that, in our experience, are not yet widely available in public or private organizations that apply communicative intervention.

Supporting organization development and capacity building

In many cases innovation involves and/or depends on the adequate functioning of farmer and community organizations or groups, such as irrigation management committees, credit groups, marketing cooperatives, commodity groups, study groups etc. For purposes of conflict resolution it can be important too that weaker parties become better organized and improve their ability to make claims. Thus, an important role for communication workers can be to contribute to organization development and human capacity building, so as to strengthen a particular group's capacity to innovate, help themselves and/or make claims. The role of change agents here can range from initiating organization development, contributing to organizational activities and processes, providing training in organizational skills, facilitating processes of organization change etc. Such activities are often inspired by 'political' sympathy with particular, often disadvantaged, groups. The term 'political' here does not refer to political parties or movements, but rather to the fact that 'strengthening a group' means almost automatically to improve their 'power position' with regard to others.

Persuasive transfer of policy and/or technological innovations

The most widespread form of communicative intervention is to persuade farmers or other target groups to adopt specific technological packages and/or to accept certain ideas or policies. The main intervention goal here is to help realize specific policy objectives (e.g. increase export earnings) by the stimulation of predefined behaviour changes (e.g. the adoption of cash crops and/or new varieties). Typically, such efforts have been in the form of comprehensive extension campaigns, which in their eventual form and method partly resembled what we have called 'advisory communication' and 'horizontal knowledge exchange'. However, whenever external[2] persuasive concerns enter an interaction between communication workers and farmers, we would prefer to call it '*persuasive transfer*' rather than 'advisory communication' or 'horizontal exchange' – even if the form may be the same – because it means that a different intervention goal and operational logic enters the scene. As part of this logic, the required role of the communication worker in persuasive transfer is much more that of a social engineer who tries to manipulate strategically the farmers' behaviour, rather than that of a consultant or facilitator. Similarly, the role of the client is different in persuasive forms of communicative intervention. Usually people do not ask to be persuaded in a specific direction, so farmers are more at the receiving end than the demanding end. Although persuasive transfer has become increasingly unpopular in discussions of communicative intervention, persuasive transfer of innovations still exists widely. Often this form of intervention is based on local or national policy decisions (e.g. to increase cotton production, or reduce the use of pesticides), or an earlier interactive process in which stakeholders agreed on the promotion of certain behaviour changes.

In this section we have tried to unravel different types of communication services and strategies, distinguished mainly on the basis of their underlying intervention goal and not on the basis of their method. In practice, several intervention goals can play a role within particular activities, in which case the distinction is more analytical than practical. In other cases these types of services can be associated with specific activities. In any case, the distinction is important in that it may help communication workers and their organizations to think about what their mission and mandate is or should be.

Agricultural Knowledge Systems and Other Extension-related Concepts

The term 'agricultural extension' refers not only to a professional practice, but also to an area of study which has generated knowledge and insight and can be studied in agricultural colleges and universities. In this section we clarify several terms used in connection with this, and also propose alternative terms in view of our wish to move away from the concept of 'extension'.

Agricultural knowledge systems

Conventional extension organizations have always been looked upon as playing a role among other institutions, functions and actors who are active in the area of agricultural knowledge, such as universities, strategic research, stations for applied research, farmers, agribusiness, agricultural magazines, agricultural schools and colleges etc. This collection of actors is often referred to as the agricultural knowledge and information system (AKIS) (Röling, 1989; Engel, 1995; FAO and World Bank, 2000). For a long time the role of extension and communicative intervention was looked on as transferring and disseminating ready-made knowledge from research to farmers, or from 'early adopters' to other farmers. This is often referred to as the 'transfer-of-technology' model of extension (Chambers et al, 1989), which fits in with a linear model of innovation. As shown earlier in this chapter, we now look at the role of communicative intervention in a much broader way. The emphasis is much more on the facilitation of network building, social learning and conflict management among a variety of actors with a view to arriving at new innovations. Thus, communication workers are seen as interacting with a wider set of actors than the knowledge institutions. Nevertheless, it remains relevant to look at issues like knowledge exchange and links between clients, extensionists, research and other parties in the agricultural knowledge system; not least since other knowledge institutions may well have an influence on whether or not communication workers can effectively play their newly envisaged roles. Communication workers might, for example, aspire to engage in interactive technology design, but find out that research institutes are unable or unwilling to cooperate and coordinate activities to that end. Thus, when talking about agricultural knowledge systems, one is immediately confronted with issues of interinstitutional cooperation and associated problems.

In order to understand the functioning and potential of communicative intervention, it remains vital to look at it in the context of other actors in the knowledge system.

Extension science/communication and innovation studies

In agricultural universities, groups have emerged that study the phenomenon of 'agricultural extension', as described by its evolving definitions (see 'Historical roots and evolving conceptions of extension'). Röling (1988) has called this academic tradition 'extension science', and new names are being invented to describe this field of study. In The Netherlands we now speak about 'Communication and Innovation Studies'. Scholars in this field systematically investigate communication for innovation processes and experiences, and connect their conclusions with more abstract and general concepts and theories. In the early days extension science was predominantly an applied science in that most of the questions and conclusions were aimed at informing communication workers how to do a better job. Thus, many theories were formulated on, for example, how to use media effectively, how to develop effective communication plans, how to manage agricultural knowledge systems. More recently, studies have appeared which are more oriented towards describing and interpreting what happens around communication for innovation processes, and which do not start from a wish to arrive at practical, prescriptive theories and recommendations. One can, for example, analyse how communication workers cope with the contradictory pressures from farmers and the government, without wishing to inform them on how to do so better. But such studies can usually be used by others to derive valuable practical lessons. Typically, communication and innovation studies borrows insights from, and sometimes adds insights to, several other social science disciplines. Originally, these were mainly communication science, social psychology, adult education and rural sociology. More recently, many more disciplines have offered inspiration to our field of study, including the sociology of science and technology, management science, systems theory, political science and anthropology.

Although communication and innovation studies is a *social* science field, it has also attracted interest from natural scientists, not least because it often focuses on those interactions between people that concern their agroecological environment. This meeting of social and natural scientists' views is partly what makes our field of study so interesting, but it also generates tensions since social scientists and natural scientists often have very different ideas about the role and potential of scientific knowledge. Apart from this, social scientists and natural scientists tend to face rather different methodological challenges, and thus tend to work in very different ways. Thus, when natural scientists start to get involved in communication and innovation studies it often takes them a while to adjust.

Extension training/communication for innovation training

Conventionally, the term 'extension training' referred to the process through which extension staff became equipped to do their job. This kind of training has also been referred to as 'extension education'. However, in view of the strong educational connotations in early definitions of extension, this latter term has also been used synonymously with extension practice itself (e.g. Supe, 1983). In any case, we now prefer the term 'communication for innovation training'. Such training provides change agents at different levels in organizations (management, field workers etc.) with insights and experiences for taking strategic and operational decisions in communicative intervention. It may cover technical, methodical and/or management issues, and it can take place in various ways; for example through formal courses, fixed or flexible curricula, practicals, supervision, distance education, workshops and organization development trajectories.

Ideally, the findings from communication and innovation studies offer inspiration to those who perform communication for innovation training. Thus, we hope that trainers can pick out elements of this book, connect these with other experiences, and translate the resulting mix of insights into training modules for communication workers.

Extension research/communication for innovation research

We can distinguish two types of extension, or communication for innovation, research. First, as an integral part of communication for innovation activities, change agents regularly need to engage in investigation and research, such as situation analysis, exploration, literature research, on-farm research, pretesting, monitoring and evaluation. Typically, such research is 'decision oriented' in that it helps communication workers and others to make decisions about the nature and content of their future activities. We refer to this kind of activity as '*decision-oriented research*', which is part of an intervention process. In order to yield useable results, this kind of research cannot be a detached activity carried out by an isolated investigator. Rather, considerable interaction with prospective clients is needed to make sure that the decisions taken are in line with their needs and requirements.

Earlier we touched on a second type of research, which is usually carried out by scholars in communication and innovation studies (or extension science; see above). Although in some cases their research may overlap with decision-oriented research, academics usually have an additional interest, which is to conceptualize and theorize about the findings. In other cases, this kind of '*conceptual research*' has little connection with decision-oriented research. It may, for example, involve social psychological experiments in a laboratory setting, or may be oriented merely towards observing the communicative intervention arena, with no intention to directly inform decision making by communication professionals. As we have discussed under the heading of extension science, conceptual research is still often applied research since it frequently seeks to develop or test theories that have practical or even prescriptive implications for communication workers. Thus, the main difference between decision-oriented and conceptual research lies in the level of abstraction and the intention of the researcher, and not so much in its applicability. As Kurt Lewin stated: 'There is nothing so practical as a good theory'. Given its theoretical aspirations, however, conceptual research will often have to meet different (i.e. academic) standards, in terms of preparation, methodology and analysis, from those of decision-oriented research.

Notes

1 Note that in some cases such conflicts are in part the result of previous interventions by others or one's own organization.

2 By 'external' we mean persuasive interests that derive from donors or governments who play a role in the 'back of the mind' of the communication worker. This is in contrast to a situation where a change agent presents advice persuasively to emphasize that he really ('internally') believes that it is in the best interest of the – perhaps even paying – farmer to solve a problem in a particular way.

Use of Communication Media in Changing Rice Farmers' Pest Management in the Mekong Delta, Vietnam

K. L. Heong, M. M. Escalada, N. H. Huan and V. Mai

Introduction

Pesticides have dominated pest management practices of rice farmers for the past 30 years. The agrochemical era of the 1960s and 1970s that had strongly influenced chemical oriented agricultural research and extension in the United States (Rossiter, 1975) is still having a dominant effect in many developing countries. Most Asian rice farmers have adopted pesticides as their main pest control tactic (Heong and Escalada, 1997b) using insecticides more frequently than herbicides and fungicides in most countries. In many cases, these insecticide applications are unnecessary and are unlikely to result in an economic return. In the Philippines, for example, about 80 per cent of insecticide sprays were misused because they were applied at the wrong time and on the wrong targets (Heong et al, 1995a). Farmers targeted most insecticides at leaf-feeding insects in the early growth stages (Heong et al, 1994; Mai et al, 1997). The most common species is the rice leaf folder (*Cnaphalocrocis medinalis* Guenee), which causes highly visible damage symptoms. Farmers generally perceive that the damage due to these pests (often referred to as 'worms') reduces yield so they apply insecticides (often referred to as 'medicine'). The less expensive and highly toxic chemicals, such as methyl parathion, monocrotophos and methamidophos, are frequently used.

However, research has shown that the common leaf-feeding insects, such the leaf folder, whorl maggot (*Hydriella philippinensis*) and army worms (like *Spodoptera litura*) that often attack the rice crop during the vegetative stages arc rarely in sufficiently high densities to reduce yield. Even when all hills were damaged by whorl maggots, no yield loss could be detected (Viajante and Heinrichs, 1986;

Shepard et al, 1990). For leaf folders, a larva could consume about 25cm^2 or less than 40 per cent of a normal leaf of *indica* rice (Heong, 1990). Incorporating this feeding rate, the rice model, MACROS, predicted that yield would decrease when the larval density reached 15 per hill (Fabellar et al, 1994), but normal larval densities are usually well below three per hill (Gou, 1990; de Kraker, 1996), mainly because of natural biological control. Thus, in most cases, insecticides applied into rice fields during the early crop stages to control leaf folders are unlikely to benefit farmers economically. Instead, they can cause ecological disruptions to the herbivore–predator relationships by shortening the mean food web chain length, favouring an increase in the population of some [herbivorous species, for example, delphacids, and causing secondary brown plant hopper pest problems (Way and Heong, 1994; Heong and Schoenly, 1998).

Farmers' insecticide use decisions do not seem to be based on economic rationale (Lim and Heong, 1984; Waibel, 1986; Rola and Pingali, 1993; Heong and Escalada, 1997a). These decisions, often made under uncertainty, are influenced more by perceptions of the pest and benefits from spraying. When decisions are made under uncertainty, people often use decision rules (Einhorn and Hogarth, 1981; Eiser, 1986; Payne et al, 1992). The term, heuristic, was introduced by Kahneman and Tversky (1973) to refer to an informal rule-of-thumb used by people in order to simplify information processing and decision making. Heuristics are developed through experience and guesswork about possible outcomes and may have inherent faults and biases (Tversky and Kahnemann, 1974; Slovic et al, 1977). Farmers' reaction to damage by leaf–feeding insects by spraying insecticides may well be due to faults in their beliefs or the heuristics that they use (Bentley, 1989). Heong and Escalada (1997a) applied the cognitive dissonance theory (Festinger, 1957) to motivate farmers to evaluate whether information expressed as a heuristic: 'Insecticide applications in the first 30 days after transplanting (or 40 days after sowing) for leaf folder control is not necessary.' After the experiments most farmers changed their perceptions. Similar farmer participatory evaluations conducted in the Mekong Delta had the same effects on farmer perceptions and practices (Heong et al, 1995b).

It has been common practice for farmers to spray the early crop stages (Heong et al, 1994; Mai et al, 1997) to control leaf folders and other defoliators. Using a 15-week season-long training programme, the Farmer Field Schools (FFS) in Indonesia significantly reduced the use of insecticides by trained farmers (Useem et al, 1992; Matteson et al, 1994; Rombach and Gallagher, 1994). Since its introduction in 1989, perhaps 2 million of Asia's more than 200 million rice farmers have attended FFS and presumably have acquired sufficient decision making skills to apply insecticides rationally. The task and related costs and time necessary to reach the remaining 99 per cent of Asia's rice farmers are thus enormous.

Extension media to communicate pest management messages has been successfully implemented in Asia (Escalada and Kenmore, 1988; Pfuhl, 1988; Adhikarya, 1994; Ho, 1996). Traditional media, such as folk songs, drama and puppet shows can also be effective (Van de Fliert and Matteson, 1990; Stone, 1992). The rat control campaign in Malaysia increased farmers' adoption of chronic poison baits from 61 to 98 per cent and physical control methods from 31 to 60 per cent (Matteson et al, 1994). In the weed management campaign in Malaysia, farmers' herbicide use, although initially increasing (Matteson et al, 1994), resulted in a 50 per cent reduction four years after the campaign was launched (Adhikarya, 1994; Ho, 1996), a phenomenon known as the 'sleeper effect' (Schramm, 1973). Such marketing strategies have also been successfully used in improving health care practices, accelerating adoption of family planning and reducing cigarette smoking and in changing attitudes towards drug abuse (Rice and Paisley, 1981; Manoff, 1985; Kotler and Roberto, 1989).

As the mass media have been proven to be the most rapid and efficient means for diffusion of innovation (Rogers, 1995), rice farmers' beliefs, attitudes and practices in spraying against leaf-feeding insects presented an opportunity for us to evaluate the use of communication media to motivate farmers. The innovation was presented as a conflict information, and farmers were motivated to evaluate it. In this paper, we report the effects of a media campaign on farmers' perceptions and practices related to pest management in general and leaf folder control in particular.

Methods

Study sites

The study sites were two districts in the province of Long An situated in the Mekong Delta in the southern part of Viet Nam. Tan Tru district covers a total of 10,200km^2, whereas the Tan Thanh district covers 42,600km^2. Agriculture is the main economic activity in these two districts, with rice as the principal crop. In addition, watermelon, ground nuts, vegetable and other cash crops are cultivated. Most farmers grow two rice crops a year, whereas some grow three. The two study sites produce a total of 244,000 tons of rice per annum, about 20 per cent of the province's production of 1.2 million tons. The total number of farmer households in Tan Tru is about 11,000 and in Tan Thanh, about 10,000, accounting for 10 per cent of the province's farmer population of 210,000 (Cuc, 1995).

Planning workshop

A workshop with participants from research, extension and agricultural communications was conducted in Vietnam to develop media materials that will motivate farmers to evaluate the heuristic: 'Spraying insecticides for leaf folder control in the first 40 days after sowing is not needed.' In the three-day workshop, several versions of a leaflet, a poster and a radio drama, were developed [see Rapusas et al (1994) for a full report]. These materials were designed to provide both the information (What is the innovation?) and the innovation-evaluation information (What are the consequences of the innovation?). They were pretested in the sites with groups of farmers, and from the feedback, final versions of the three media were mass produced. A distribution plan was developed by the campaign management committee, headed by the Vice Chairperson of the Peoples' Committee of the province of Long An, and on 8 September 1994, the campaign was launched by the Vice Minister of Agriculture in a ceremony where a few selected fanners who had carried out the evaluation [see Heong et al (1995b)] presented their findings.

Material distribution

A total of 21,000 leaflets were distributed to all households in the two districts through the district Plant Protection offices. Four thousand posters were posted in village billboards, coffee shops, supply shops, government offices and markets. On the leaflets and posters, a message to encourage farmers to contact the Plant Protection Department to learn more about IPM concepts was also included. The drama entitled 'Well, I shall try', depicted a conversation between a farmer who had conducted the evaluation encouraging another farmer to try it (script in Appendix). Three local actors were employed to produce the drama, recorded in 40 cassette tapes that were distributed to radio stations for broadcasting twice a week during the crop season (September 1994 to January 1995) and to coffee shops to be played over their audio systems. In addition, the Long An provincial government built nine billboards measuring 3 × 2m that were placed along the main roads and market places. Vehicles with public address systems and posters were also used. Distribution of the materials was monitored through a management monitoring survey conducted in November 1994.

Data collection

The research design used was the pretest–post-test design (Campbell and Stanley, 1973; Neuman, 1991), which involved a pretest, the intervention, a monitoring survey and three post-tests. We used quantitative research methods for data gathering and qualitative methods to complement the data, in all surveys. The qualitative methods that we used included non-structured conversations with farmers that provided opportunities for probing into individual farmers' responses, focus group interviews to obtain group consensus in responses and participatory observations. In addition, supplementary data on pesticide sales, prices and farmer training activities over the research period were obtained from the provincial agricultural office.

Five evaluation surveys were used, the pretest, the management monitoring survey, the post-test in February 1996, 18 months after introduction, the post-test in March 1997, 31 months after introduction and the post-test of farmers in the other 12 districts in Long An province conducted in September 1996. The variables and questions used in each survey were determined by conducting a conversational analysis in an exploratory field research carried out by the authors. Each questionnaire was then developed, translated into Vietnamese and pretested with 20–30 respondents. Ambiguous questions were modified to ensure clarity and further pretested, if necessary. In order to capture farmers' direct responses, we used open-ended questions wherever possible. The surveys were administered by students from the local agricultural institute. The provincial agricultural technicians supervised the operations but had no input in administering the questionnaires. For each survey, a training course, which included a practice session, for all involved in the survey was conducted by the authors to ensure quality and consistency. The student interviewers were trained to record the exact words farmers used in response to each question. We supervised each survey, and the field data obtained were immediately coded and entered into the computer using a spreadsheet program. Whenever errors in data entry were encountered, they were referred back for clarification. We also conducted quality assurance checks when the surveys were being conducted. Each survey was administered within a week.

The pretest survey, conducted in August 1994, collected data on farmer profiles, pest management knowledge, perceptions, attitudes and practice from a sample of 633 randomly selected respondents in the two districts. Details of the survey are reported in Mai et al (1997). A management monitoring survey was conducted in November 1994 with a sample of 2226 randomly selected farmers, to monitor the distribution and reach of the media materials. The first post-test survey was conducted in February 1996 with a sample of 452 randomly selected farmers. In this survey, besides monitoring the same variables as in the pretest survey, we added seven perception questions. In March 1997, we conducted the second post-test survey using the same instrument with a sample of 628 randomly selected farmers. To monitor diffusion of the innovation to other districts in the province, a survey of 1449 randomly selected farmers from the other 12 districts in Long An province was conducted in September 1996.

Analytical methods

The field data were coded and entered into a spreadsheet program. Frequency distributions and cross-tabulations were generated by using Statistical Analysis Systems (SAS, 1985) and Statistical Package for Social Sciences for Windows 7.5 (SPSS, 1997). Means were compared using *t*-test procedures, and both parametric and non-parametric statistics were used for correlation and testing of variables.

Belief index

Farmers' beliefs were measured through the use of five statements to which respondents were asked to state whether they agreed, disagreed with them or were indifferent. A three-point Likert scale (1 for the preferred answer, 2 for indifference and 3 for the not preferred) was used to score responses. The three statements used to assess the components of belief about leaf folders were: 'Leaf folders in the first 40 days after sowing (DAS) can cause severe damages to the crop'; 'Leaf folders in the first 40 DAS will cause yield loss'; and 'Spraying in the first 40 DAS to control leaf folders is necessary'. Two other statements were related to general insecticide use: 'Applying insecticides will increase yields' and 'Killing natural enemies by insecticide spraying will not cause more pest problems'. The belief index for each respondent was computed by summing across the scale ratings and statistically compared. The questions were framed in such a way that the bipolar points of the index would be 5 and 15 (5 means that all the statements were the preferred answers, and 15 means that all the statements were not preferred).

In the three follow-up post-tests, an additional seven belief statements were used (Table 12.5), and farmers were asked to respond whether they disagreed, were indifferent or agreed with the statements.

Results

Profiles of rice farmer respondents

Profiles of farmer respondents in the pretest, the three post-test surveys in the study sites, Tan Tru and Tan Thanh and the post-test in the remaining 12 districts are summarized in Table 12.1. Most farmers interviewed were between the ages of 31 and 50 with an education of between 1 and 9 years. Only a small proportion (<8 per cent) had not attended school. Farm sizes were generally less than 1ha, and the yields reported varied between 3 and 5 tons ha^{-1}.

Farmer access to communication media

From the pre-test survey, about 66 per cent of the farmers interviewed said that they owned a radio. Farmers in the two districts generally listened to two radio stations, Radio Ho Chi Minh (49 per cent) and the Long An provincial station (46 per cent). These two stations were used to broadcast the mini drama. The preferred times for broadcasts were 5.00–8.00 am (40 per cent), 6.00–8.00 pm (29 per cent) and 12.00–2.00 pm (16 per cent). Farmers said that they preferred programmes with farming information (46 per cent), news (17 per cent) and drama (16 per cent). Among the printed materials farmers frequently read were newspapers (47 per cent), leaflets (37 per cent) and magazines (8 per cent). About 44 per cent of the respondents owned a television and the most common stations that they had access to were TV Ho Chi Minh and TV Can Tho.

Delivery and reach of media materials

In the management monitoring survey conducted two months after the materials were distributed, 97 per cent of the farmers interviewed were aware of the campaign. The most commonly cited source farmers heard from was the leaflet (89 per cent), followed by the radio drama (72 per cent), poster (69 per cent), the demonstration plots (43 per cent), friends (34 per cent) and the billboards (34 per cent). Most of the leaflets were delivered to the households (96 per cent). The radio

< 2	15.5	6.7	5.9	4.6
2.1–3	26.7	11.1	17.7	9.7
3.1–4	34.7	25.8	33.5	21.1
4.1–5	18.2	28.0	26.4	29.2
> 5	4.7	28.5	16.5	35.5

drama was heard over radio Ho Chi Minh (76 per cent) and provincial radio (22 per cent), whereas the posters that were displayed in buildings along the road were most frequently observed (60 per cent), followed by those in the coffee shops (16 per cent), market (5 per cent), schools (4 per cent) and friends' houses (3 per cent).

What farmers learnt from the media materials

In the post-test, we used an open-ended question to assess what farmers learnt from the three media materials. Farmers learnt that there was no need for insecticide spraying against the leaf folder in the first 40 DAS (69 per cent), that avoiding the use of insecticide during this period saves money and labour (30 per cent), that spraying early in the season is detrimental to natural enemies (20 per cent), how to conduct an experiment (14 per cent), that leaf folder damage during the early growth stages do not reduce yields as crops recover (11 per cent), that insecticide spraying can be detrimental to one's health (13 per cent) and that insecticides pollutes environment (6 per cent). When they obtained the information from the media, about 56 per cent of the farmers said that they conducted the experiment, 15 per cent said that they stopped spraying for leaf folders in the first 40 DAS, and 15 per cent said that they did not do anything about it. The main reasons provided for not responding were that they were worried about pest attacks when they did not spray (34 per cent), afraid of yield loss (19 per cent), did not believe in the message content (11 per cent), had no time to experiment (8 per cent) and about 6 per cent did not understand the information.

Changes in farmers' insecticide use patterns

Changes in farmers' insecticide use over the 31-month period are shown in Table 12.2 and Figure 12.1. The mean number of sprays that farmers applied declined from 3.35 per farmer to 1.56 18 months after distribution. There was a slight increase to 1.76, although not significant, a year later. The mean number of insecticide sprays by farmers in the 12 districts outside the study sites in 1996 was 1.58, which was not significantly different from the study sites. The proportion of farmers who

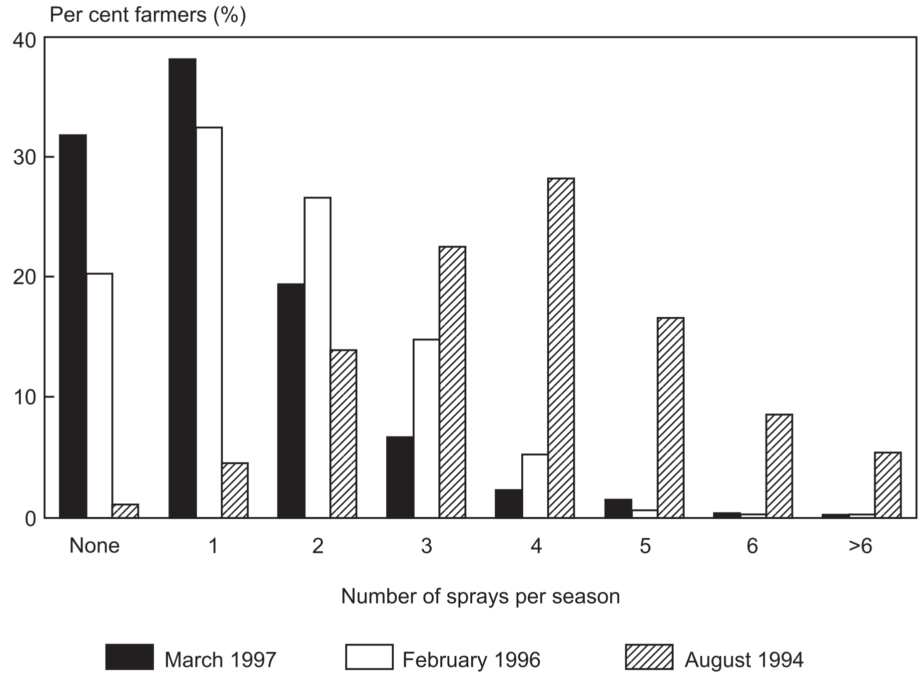

Figure 12.1 *Changes in rice farmer's insecticide spray frequencies in Tan Tru and Tan Thanh districts, Long An province, in August 1994 just before the introduction, 18 months after in February 1996 and 31 months after in March 1997*

did not use any insecticides increased from 1 per cent in pretest to 20 per cent in the first post-test and to 32 per cent in the second post-test. In the 12 districts, 20 per cent of the farmers interviewed did not apply any insecticides. The insecticide spray frequency distributions significantly shifted to the left with more farmers applying only once or twice after the introduction of the media materials (Figure 12.1). The proportion of farmers spraying during the early tillering, late tillering and booting stages declined significantly (Friedman test chi-square = 7.6, $P < 0.05$) (Figure 12.2). In the pretest, 59 per cent and 84 per cent of the farmers sprayed during the early and late tillering stages, respectively. In the first post-test, the proportion of farmers spraying in the early and late tillering stages dropped to 28 per cent and 42 per cent, respectively, and in the second post-test, these proportions further declined to 0.2 per cent and 19 per cent, respectively. In the 12 districts, 13 per cent of the farmers sprayed during the early and 24 per cent in the late tillering stages. The proportion of farmers spraying in the reproductive and maturing stages initially declined in the first post-test but increased in the second post-test, but were still lower than that in the pretest.

Although the number of insecticide sprays was reduced over the period, farmers' spray targets had not significantly changed (Friedman test chi-square = 0.33, $P > 0.05$). The rice leaf folder and other leaf-feeding insects remained the main targets,

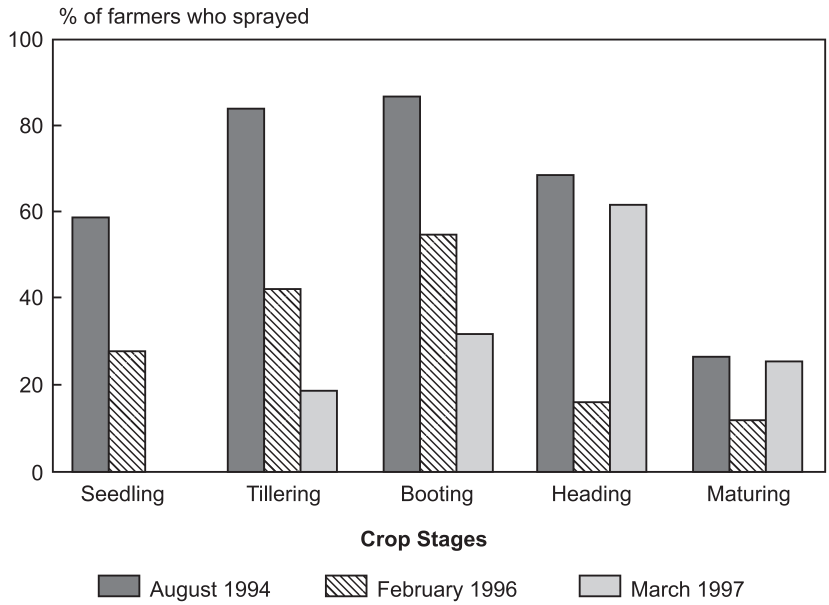

Figure 12.2 *Rice farmers' insecticide applications in different crop stages in Tan Tru and Tan Thanh districts, Long An province, in August 1994 just before the introduction of the media materials, 18 months after in February 1996 and 31 months after in March 1997*

accounting for 44 per cent, 52 per cent and 53 per cent of farmers' applications in the 1994 pretest, 1996 post-test and 1997 post-test, respectively (Table 12.3). Farmers' targets in the 12 districts were also the same, with 40 per cent of the sprays used for rice leaf folder control. The types of insecticides and farmers' belief that insecticides can be harmful to health (Table 12.5) have also remained relatively unchanged. Methamidophos, monocrotophos and methyl parathion [all

WHO category I pesticides (CIRAD, 1991)] accounted for 48 per cent of the sprays in the 1994 pretest and 1996 post-test (Table 12.4). In the 12 districts outside the study sites, these three WHO category I insecticides constituted 33 per cent of the sprays used.

Changes in farmers' beliefs

The belief index reduced significantly from 11.25 (±0.18 at 95 per cent CL) in the 1994 pretest to 8.22 (±0.27 at 95 per cent CL) in the 1996 post-test and 7.62 (±0.24 at 95 per cent CL) in the 1997 post-test. The higher belief index in the pretest meant that more farmers had non-preferred beliefs. In the 12 districts, the belief index was found to be 8.11 (±0.85 at 95 per cent CL). Table 12.5 shows changes in farmers' beliefs in the three statements related to the rice leaf folder problem to the two statements relating to insecticide use. Except for the statement

Critical values of chi-square tests at d.f. = 2, $P = 0.05$. 5.99 and $P \approx 0.01$. 9.21.

[a,b] Significant differences at $P = 0.01$ and $P = 0.05$ probability levels, respectively, from post-test 1996.

[c] Significant differences at $P = 0.01$ probability levels, respectively, between pretest (1994) and post-test (1996).

'Applying insecticides will increase yields', farmer responses to the four other statements were significantly changed. In the 12 districts, similar farmer responses were obtained (Table 12.5), implying that although the campaign was launched in the study sites, it had significantly influenced farmers in other districts quite distant from the sites. In the 1997 post-test, responses to the seven additional belief statements were significantly different from that of the 1996 post-test, implying that farmers had developed stronger beliefs that spraying insecticides in the first 40 DAS was unnecessary and a waste of money, affected health and contaminated the environment (Table 12.5). Similarly, in the 12 districts outside the study sites, the farmers' responses to these statements were also significantly changed.

Benefits from not spraying in the early season

In the post-tests, farmers were asked an open-ended question as to the benefits for not spraying insecticides in the first 40 DAS. Savings in costs (insecticide and labour) were cited by 89 per cent of the farmers, followed by reducing health risks (25 per cent), less pollution to the environment (17 per cent) and protection of natural predators (12 per cent). These benefits were displayed in the poster placed in various public places. Most of the farmers (97 per cent) said that they will continue not using insecticides in the first 40 DAS in the next season.

Relationship between belief index and insecticide use

Farmers' insecticide use frequencies were highly correlated with the belief index values in all three surveys, pretest (Pearson 0.109, $p < 0.05$), post-test 1996 (Pearson, 0.414, $p < 0.01$) and post-test 1997 (Pearson. 0.285, $p < 0.01$). These positive relationships imply that individual fanners with high belief indices had a higher tendency to spray insecticides (Table 12.6). Similarly, the correlation in the post-test of the 12 districts in Long An province was also significant (Pearson, 0.36, $p < 0.01$).

Farmer-to-farmer spread and multiplier effects

In the 1996 post-test, about 77 per cent of the farmers who were aware of the media materials ($n = 400$) said that they discussed the message content with members of his or her household, and 67 per cent discussed it with other farmers. Persons with whom the information was discussed included the spouses (57 per cent), the sons and daughters (31 per cent), children (19 per cent), siblings (12 per cent) and other relations (16 per cent). Some farmers recalled communicating the infor-

mation from the media to more than ten persons (33 per cent), whereas most said that they had spoken to five or less persons (44 per cent). The most common situations where the information was discussed were in the field (36 per cent), in the coffee shops (24 per cent) and at dinner parties (24 per cent).

The media approach in the project sites in Long An province stimulated other provincial governments in the Mekong Delta to launch their own programmes using the approach. Between September 1994 and March 1997, 15 provincial governments initiated their own programmes, spending about US$151,000, distributed 340,000 leaflets, 35,000 posters, organized 1390 demonstration plots and broadcast the radio drama about 1550 times. In addition, a total of 356,600 farmers were invited to participate in testing whether early season spraying for leaf folder control was necessary.

In 1996, a post-test survey of 1499 farmers in the 12 districts of Long An province, besides the study sites, was conducted by the Provincial Plant Protection Department to evaluate the spread effect. About 82 per cent of the 1449 farmers interviewed said that they had heard about the heuristic, and 64 per cent said that they had tried it. Of those who tried, 77 per cent said they had stopped spraying in the first 40 DAS. The spray frequency (Figure 12.3) showed that about 20 per cent of the farmers had not applied any insecticides, and most farmers (59 per cent) applied one or two sprays each season (average 1.6). About 37 per cent of the farmers applied their first sprays in the first four weeks, 50 per cent in the second

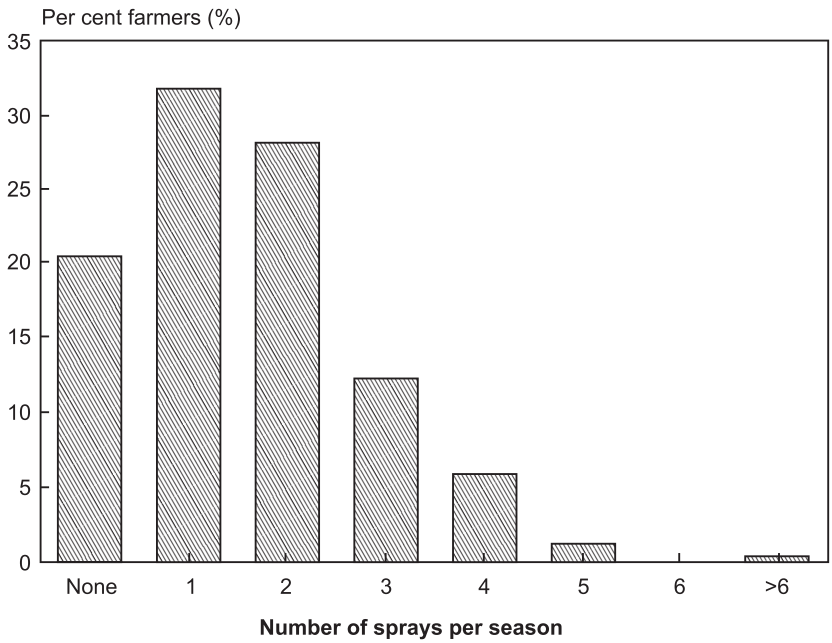

Figure 12.3 *Insecticide spray frequencies of rice farmers in 12 districts in Long An province in September 1996, n = 1449*

four weeks and the remaining 13 per cent after the ninth week. Using farmers' responses to the same five belief statements as in the pretest and the two post-tests, the belief index of farmers in the 12 districts was found to be 8.11 (±0.08 at 95 per cent CL), which was significantly lower than that of the pretest but not significantly different from the 1996 post-test in the study sites. It is evident that the communication media introduced into the two study districts have influenced farmers' pest management beliefs and practices in the whole of Long An.

Farmer field schools

During the study period, a training programme using the FFS approach (Useem et al, 1992; Matteson et al, 1994) was implemented in the province. Table 12.7 shows the number of farmers who were trained by FFS. At the end of 1994, the FFS reached 467 farmers or 2.2 per cent of the households in study sites, whereas the media reached 97 per cent of the population. By the end of 1996, the number of farmers trained in Long An was 7451, accounting for 3.5 per cent of the total farmer households in Long An province. The 1996 post-test survey of 12 districts in Long An province showed that the media reached 82 per cent of the farmer households. The number of farmers trained in the study sites was 1827 or 8.7 per cent. In the 1996 post-test, there were 112 farmers in our sample who had been to the FFS. We regrouped the data and compared the responses of FFS trained farmers and those who had not attended the training. Table 12.8 shows details of the comparison of some of the attributes. FFS trained farmers sprayed less but not significantly lower than untrained farmers, and there were more FFS trained farmers who did not spray any insecticides. The belief index of FFS trained farmers was also lower, although not significantly different, and the proportion of farmers who applied their first insecticide sprays in the first four weeks after sowing was also lower. There was, however, little difference in spray targets as the proportions of sprays for the control of leaf feeding insects was similar. The types of insecticides used also did not differ.

Table 12.9 shows farmers' responses to the belief statements. In all cases, the responses of the FFS-trained farmers and the untrained farmers were not significantly

	methyl parathion	9.3	6.9
	monocrotophos	6.7	10.8
	deltamethrin	7.7	5.9
Percentage of farmer who applied first sprays in first 4 weeks		24.1	38.8

different. For instance, fewer FFS trained farmers believed that insecticides would increase yields (28.6 per cent and 38.0 per cent), leaf folders in the early crop stages could cause yield loss (21.4 per cent and 27.8 per cent), and spraying during the early crop season would be necessary (25.0 per cent and 32.9 per cent). This implied that the FFS training further reinforced farmers' beliefs that leaf folders were not important problems and that spraying was unnecessary.

Insecticide costs and sales in Long An province

The costs of the commonly used insecticides have not changed significantly over the study period (Table 12.10). The sales volume records of five retailers showed that the proportion of insecticide sales declined from 37 per cent of total sales in 1994 to 21 per cent in 1997.

Discussion

There are strengths and weaknesses in indigenous farmer knowledge as observed among Honduran farmers (Bentley, 1989), and farmers' beliefs in pests and their perceptions of the potential damage and losses are examples of such weaknesses. Rice farmers in Asia generally overestimate losses due to highly visible pest damage, such as the rice leaf folder (Heong et al, 1994) and stem borers (Lazaro et al, 1993). In Honduras, Bentley (1989) found that farmers were worried about *Diabrotica* beetles, which are large and colourful but not important pests. In insecticide use, farmers' perceived benefits seem to be much higher than the actual benefits. Since perceptions, rather than the economic rational, determine the decisions of farmers, changing these perceptions may reduce the perceived benefits and

intentions to spray. By using the conflict approach, farmers in the Philippines were motivated to stop their early season spraying (Heong and Escalada, 1997a). Using communication materials, farmers in the study sites were similarly motivated and reduced their insecticide sprays by 47 per cent, from 3.35 to 1.76 sprays per season. This reduction seems to be attributed to the change in beliefs as indicated by the reduction in the belief index from 11.3 to 7.6. The direct relationships between number sprays and the belief index further support this conclusion.

Farmers' insecticide spraying in the early crop stages had clearly reduced. Before the introduction of the communication materials, about 60 per cent, 82 per cent and 84 per cent of the farmers applied insecticides during the early and late tillering and booting stages, respectively. Eighteen months after introduction, farmers' spraying during these stages had significantly reduced to 25 per cent, 41 per cent and 55 per cent, respectively. Further reductions to 0 per cent, 19 per cent and 30 per cent were observed 31 months after introduction. As the content of the communication campaign was to motivate farmers to reduce early season spraying, this reduction in early season spraying implied that the campaign had affected farmers' insecticide use. At the heading and maturing stages, there were initial reductions in farmers using insecticides, and spraying was increased although not significantly higher than in the pretest. This increase was also reflected in the increase in mean number of sprays per season, from 1.55 to 1.76. In the 12 districts, the mean number of sprays was 1.58 at about 25 months after launching in Long An. Since these two surveys were done in different crop seasons, the general reduction in the number of insecticides in the whole province of Long An province reflected the effect of the media and not seasonal differences.

Although there appeared to be a substantial perception change in a large proportion of farmers, the rice leaf folders and other leaf feeding insects remained the targets of those farmers who were spraying. These sprays were used later, implying that farmers were still worried about the leaf feeders, particularly leaf folders, that infest crops at the later crop stages.

While the communication materials were introduced, IPM training programmes through the FFS approach were also implemented in the study sites. In September 1994, when the media project started, there were 467 FFS trained farmers in the project sites. When the first post-test was conducted in February 1996, there were 991 FFS trained farmers, and in March 1997, the number increased to 1827. These accounted for 2.2 per cent, 4.7 per cent and 8.7 per cent of the farmer households in the study sites at the time when the surveys were conducted. When we conducted post-tests in 1996 and 1997, most of the FFS trained farmers had been exposed to the media materials. The general reduction in insecticide use and farmers' perception change might be due to one or both of these interventions. In the study sites, the reduction in insecticide sprays, especially in the early crop stages, and the change in perception, were widespread, even among farmers who had not attended FFS. The relatively small proportion of farmers exposed to FFS (< 10 per cent) may not be able to account for these changes over a large proportion of the farmers in the study area. Similar changes were also observed among farmers in other districts of Long An province, where only 3.5 per cent of the farmer households had attended FFS.

We found that FFS trained farmers sprayed less insecticides and had lower belief index scores, although these were not significantly lower than those farmers who had not attended the FFS. In response to the belief statements, more FFS trained farmers had preferred responses than untrained farmers. As farmers in Long An were exposed to the media campaign before attending the FFS, the training further reinforced the perception change initiated by the media.

In the study sites, the media materials were distributed only for one season in 1994, and their effects on farmers' perceptions and practices were sustained for 31 months. Another 15 provincial governments adopted the same approach and extended the campaign to the whole of the Mekong Delta, with an estimated farm household population of about 2 million. It is evident that the new information had diffused to a large population and had reduced the uncertainty of farmers' attitudes toward not using insecticides. The media materials provided information aimed at reducing uncertainty, and this effect was evident from the significant reduction in the belief index. The information was aimed at reducing insecticide use in the early crop stages and a significant reduction in farmers' insecticide spraying during these crop stages was observed.

The adoption rate of an innovation depends on its characteristics (Rogers, 1995). In this case, the innovation has high relative advantages in terms of savings in chemical and labour costs. The innovation is also testable. The campaign emphasized this, and its benefits are also observable. Initially, the innovation was in conflict with farmers' perceptions. However, since it was presented together with an evaluation method and related information, it served as an important incentive to change perceptions (Heong and Escalada, 1997a). Such a change may be further reinforced and sustained by more frequent mass media and training programmes.

Since the approach was easy and inexpensive to adopt, it stimulated 15 provincial governments to establish their own programmes with provincial funds extending the campaign's reach to the entire Mekong Delta. The post-test survey of 12 districts carried out in September 1996 showed that a large proportion (82 per cent) of the farmer households (about 2 million) had been reached, and many had ceased their insecticide spraying for leaf folder control in the early crop stages. In these provinces, the approach appears to be part of the agricultural technicians' routine tasks (or 'routinized'). It is evident that to enhance adoption, the innovation, besides being attractive to its potential adopters, will also need to be attractive to its potential implementers.

Mass media channels are relatively more important at the knowledge stage in the innovation-decision process (Rogers, 1995). They can reach a large audience rapidly, create knowledge and spread information, and these can lead to changes in some weakly held attitudes. Spraying insecticides at the early crop stages, though very common among farmers, may be a weakly held attitude. To change more strongly held attitudes, like insecticide spraying at other times of crop growth for high yields, might require interpersonal channels, like face-to-face exchange means. The information on the leaflets and posters encouraging farmers to contact the Plant Protection Department to learn more about pest management was primarily aimed at facilitating this process.

Discontinuance, a decision to reject an innovation after having previously adopted it (Rogers, 1995), among the adopters is a high possibility. This is especially so because negative messages about the innovation will continue to circulate, through both the mass media and interpersonal networks. Although the results of this study seem to show that insecticide spraying during the early crop stages has been reduced, it is difficult to expect one campaign to sustain the adoption of the innovation. For this cessation of early season spraying to continue, there is a need to provide the same information frequently or similar information framed differently. In addition, there is a need to monitor changes and develop programmes to fully institutionalize and 'routinize' into ongoing practices and value systems of adopters.

Acknowledgements

The work was supported by the Rice IPM Network coordinated by IRRI and financed by the Swiss Agency for Development and Cooperation (SDC). We are grateful to many persons who have assisted in this project. In particular, we thank Madam Tran Thi Sua, the Vice Chairperson of the Peoples' Committee of Long An province, the former Vice Minister of Agriculture of Viet Nam, Mr Le van The, Mr Nguyen Son Nam, Director of Agriculture in Long An province and Madam Do Thi Ngoc and Mr Tran Huu Khuong, the former and present Directors of Plant Protection Department in Long An Province, who provided support and additional resources; Madam Tran Thi Mai Phuong, the Vice Director of the Plant Protection Department in Long An province, Mr Nguyen Chi Thien, Chief of Plant Protection Station in Tan Tru District, Mr Nguyen Van Vu, Chief of Plant Protection Station in Tan Thanh District, who helped organize the surveys; the students who served as enumerators and the farmers in the project sites who had responded to our questions. In addition, we thank Ms Amor Lazaro, for her assistance in processing the huge data sets; Mr Pham Minh Sang, who assisted in the translation, Ms Carolyn Dedolph and Ms Hermie Rapusas, who helped in the material design workshop.

Appendix

Radio drama script used in the broadcasts in Long An province

> Scene: Early one morning in the rice field of Uncle Hai with Uncle Nam, his neighbour passing by carrying a knapsack sprayer
>
> Uncle Nam: Hey Uncle Hai! Why don't we have some coffee instead of visiting your field so early in the morning?
>
> Uncle Hai: Oh, I am watching some friendly insects attacking the worms. How about you? What are you spraying for?
>
> Uncle Nam: My God! My crop is just 10 days old, but there are so many thrips. It looks terrible. So I have to spray it now. Ah, you just mentioned friendly insects. What are they?
>
> Uncle Hai: Take your time. Put down your sprayer and I will tell you what they are.

Uncle (in Vietnamese, Bac) is used as a sign of respect when addressing a senior person in Vietnam.

Uncle Nam: Uh! Uh! I am very worried about my crop. How can I take my time? I will only stay for a short while.

Uncle Hai: Don't worry about thrips. Look at my field. There are lots of thrips there too. Sit down and I will tell you something interesting.

Uncle Nam: Okay. I will sit down.

Uncle Hai: You don't see any flies in my field, do you?

Uncle Nam: There are spiders. Everybody knows that.

Uncle Hai: And what about that insect on the leaf?

Uncle Nam: Quit joking with me. Even children know that it is a dragonfly.

Uncle Hai: Ay! It's that easy. I've just answered your questions. Those are the friendly insects. And now do you know why they are called friendly insects?

Uncle Nam: No. Why?

Uncle Hai: Because they live in the rice fields. Sometimes farmers think they are harmful but they really don't feed on the rice plants. Instead, they are looking for brown plant hoppers, leaf folders, stem borers, army worms and case worms to eat. They are farmers' friends because they eat these bad insects. So you don't have to spray to get a good crop.

Uncle Nam: A good crop without spraying? You are joking with me again. What does your crop look like without insecticides?

Uncle Hai: Ay! Ay! Do you remember my last crop? I got more than 30 gia per cong. You can ask my neighbours to confirm that I did not spray any insecticides.

Uncle Nam: Uhhhhh. It sounds ridiculous. I would like to know why.

Uncle Hai: Okay. Do you remember the situation in my field last season? The rice leaf folder damages looked very serious, but I did not spray. And I still got a good crop. Now look at my field. There are thrips and leaf folders as well, but I shall still not spray.

Uncle Nam: Really??

Uncle Hai: Sure!! During the first 40 days after sowing, rice plants can recover from leaf removal by leaf folders. If you spray, you will waste money and sometimes you will suffer from brown plant hopper damages.

Uncle Nam: What a surprise!! It is hard to imagine.

Uncle Hai: It takes some time to explain the details. You have to buy me a drink.

Mr Ha, the local agricultural technician joins the two farmers.

Mr Ha: Hey!! What are you talking about? I just heard 'buying a drink'. Is there something interesting??

Uncle Hai: Uh! Uh! By the way, Mr Ha, can you tell us about testing whether early season insecticide spraying is needed in the field? You advised me about the experiment last season.

Uncle Nam: Well. Mr Ha, please tell me about it, and I can also try it in my field.

Uncle Hai: Oh, it is very easy.

Mr Ha: Yes. It takes some time to describe this, but the experiment is easy to perform. Now how many cong of field do you have? How old is your crop? Are you going to spray right now?

Uncle Nam: I have 5 cong. My crop is 10 days old. I am going to spray this morning for thrips and leaf folders.

Mr Ha: Well. It is good that you have not sprayed yet. If you want to try, you can divide your field into two parts. Do not spray one part of 2 or 3 cong. Spray the rest as normal. At harvest, we can compare the yields of these parts. You may find that there is no difference in yields.

Uncle Nam: Two or 3 cong? That is too big. What if something goes wrong?

Mr Ha: I assure you that there will be no yield difference. If you are still worried, use one cong as the unsprayed plot. I am afraid you might be sorry for unnecessarily spending money in insecticides and spraying.

Uncle Nam: Are you sure? Okay, I will follow your advice and try the experiment.

Uncle Hai: Come on Uncle Nam! I am sure. I have grown two crops without spraying in the first 40 days and have no yield loss. I save money and work and also have no hopper problems.

Uncle Nam: Well, I will try.

Landcare and Livelihoods: The Promotion and Adoption of Conservation Farming Systems in the Philippine Uplands

R. A. Cramb and Z. Culasero

Introduction

Agricultural land degradation in the densely populated, steeply sloping upland regions of the Philippines has been recognized as a major environmental problem in the past three decades, with significant on-site and off-site impacts (Cramb, 1998). Conservation farming systems have been developed, such as the widely promoted Sloping Agricultural Land Technology (SALT), based on contour hedgerows of shrub legumes, but sustained uptake by farmers has been limited (Cramb, 2000; Cramb et al, 1999, 2000). In recent years, interest has focused on the potential of the landcare approach to enhance the development, dissemination and adoption of appropriate conservation farming measures (Mercado et al, 2001).

Landcare emerged in the mid-1980s in Australia and in the late-1990s in the Philippines as an important strategy for developing collective action at the local level to deal with problems of agricultural land degradation. The landcare approach centres on the formation of community landcare groups, supported to varying degrees through partnerships with government and non-government agencies. Campbell defines a community landcare group as 'a group of people concerned about land degradation problems, who are interested in working together to do something positive for the long-term health of the land' (1994, p31). Such groups identify problems at the local level and mobilize information, community effort and finances to help improve the management of their soil, water, vegetation and other natural resources. It is widely held that this is a more effective strategy for

Reprinted from Cramb R A and Culasero Z. 2003. Landcare and livelihoods: The promotion and adoption of conservation farming systems in the Philippine Uplands. *Int. J. Agric. Sust.* 1(2), 141–154, Earthscan, London.

Figure 13.1 *Location of principal landcare sites in Mindanao, Southern Philippines*

achieving adoption of sustainable farming practices than strategies involving government regulation or the top-down transfer of technology.

This paper reports some of the results of a participatory evaluation of the Landcare Programme in Mindanao in the Southern Philippines (Figure 13.1). The evaluation study was undertaken in the final phase of a four-year action research project (1999–2003) funded by the Australian Centre for International Agricultural Research (ACIAR). The focus of this paper is Barangay Ned, part of Lake Sebu Municipality in the province of South Cotabato in Southern Mindanao. The Landcare Programme in Barangay Ned is of particular interest because it has been faced with extremely difficult conditions, has received minimal outside support, and thus indicates perhaps the basic requirements for achieving an accelerated impact on upland farming systems in the Philippines. The sustainable rural livelihoods approach was used in this study as a framework to understand, explain and evaluate the impacts of the Ned Landcare Programme.

Background

The Landcare Programme in the Philippines

Independently of the Australian Landcare Programme, landcare in the Philippines grew out of efforts to promote soil conservation innovations among farmers in the upland municipality of Claveria in Northern Mindanao (Arcenas, 2002; Sabio, 2002). The Department of Agriculture (DA) began promoting contour hedgerows of shrub legumes in the early 1980s, in the form of the SALT package. In 1987, the International Rice Research Institute (IRRI) in collaboration with the DA initiated a farmer-to-farmer training programme in Claveria to enhance adoption. By 1992 up to 80 farmers had adopted the technology.

The International Centre for Research in Agroforestry (ICRAF) took over the IRRI research site in Claveria in 1993 and proceeded to conduct field trials on contour hedgerow systems. In 1996 ICRAF identified a low-cost farmer adaptation of contour hedgerows – the use of natural vegetative strips (NVS) as an alternative to the more complex and labour-intensive method of establishing and maintaining hedgerows of shrub legumes or forage grasses (Arcenas, 2002; Mercado et al, 2001; Sabio, 2002; Stark, 2000). A three-person extension team, comprising a farmer who had adopted NVS, a DA extension agent and an ICRAF technician, was formed to promote the NVS technology. The team worked initially with individual farmers in various villages (*barangay*), but the interest was such that group sessions were organized, involving 20–25 participants. At one of these group-training sessions in 1996, 20 farmer leaders, at the suggestion of one of the facilitators, decided to form a farmer organization to promote the NVS contour hedgerow system within the Claveria community. The organization was named the Claveria Land Care Association (CLCA).

The Landcare Programme in Claveria developed into a triangular partnership between the CLCA (a people's organization, working collectively to encourage conservation farming among its members), ICRAF (an international non-government organization, providing technical and logistic support and facilitation) and local government units (providing public resources and official support for the Association). As a result of this partnership, by early 2000 the CLCA had grown to include 16 chapters, 105 sub-chapters, and about 800 individual farmer members. Adoption of NVS technology also increased dramatically, from about 75ha in 1996 to more than 300ha in 1999. Arcenas (2002) reports that all partners credited the farmer-based group extension approach of the CLCA as the principal factor in this increased level of interest and adoption.

The success of Landcare in Claveria encouraged ICRAF in 1998 to introduce the approach at its Central Mindanao field site in the Municipality of Lantapan in Bukidnon (Figure 13.1), and to seek external funding both to support the programme and to evaluate its potential as a model for community-based natural resource management throughout the Philippine uplands. Operational funding was obtained from the Spanish Agency for International Cooperation (AECI). As mentioned above, the ACIAR funded an action research project from 1999 to 2003 to augment and help evaluate the ongoing Landcare Programme in these and other sites.

The ACIAR Landcare Project

The ACIAR Landcare Project helped support the Landcare Programme in and around the Claveria and Lantapan sites, as well as a third site in Southern Mindanao – Barangay Ned (Figure 13.1). Previous projects implemented in Barangay Ned by the Southeast Asian Regional Centre for Graduate Study and Research in Agriculture (SEARCA) had sought to develop and promote conservation farming technologies, partly through the formation of farmer work groups. Hence this site was readily included in the Landcare Programme, with SEARCA as the facilitating organization, providing a further opportunity to test the replicability of the landcare approach as it had evolved in Claveria.

The principal aim of the ACIAR Landcare Project was to test the effectiveness of the landcare approach as a tool to enhance the adoption of conservation practices suited to the needs of upland farming communities in the Philippines. As in Australia (Campbell, 1994; Cary and Webb, 2000; Lockie and Vanclay, 1997), 'the landcare approach' in the Philippines means many things, making evaluation difficult. In the ACIAR project, the impact of landcare was to be evaluated in terms of: (1) the adoption of conservation practices (and the effect of these practices on natural resources); and (2) the relevance of the approach as a model for local and regional extension services. That is, the project was interested in the adoption of both landcare *technologies* and landcare *processes and institutions* (notably the formation and development of landcare groups and networks). These impacts were seen to be critical to the achievement of the longer-term outcomes of rural poverty reduction and environmental conservation – in short, sustainable rural livelihoods.

Methods

The sustainable rural livelihoods framework

A major methodological advance in rural development research in recent years has been the recognition that rural households are not necessarily focused exclusively on increasing crop or livestock production and incomes (let alone on resource conservation), but undertake a range of activities, both on- and off-farm, depending on the resources to which they have access and the livelihood strategies they are able to pursue at any given time (Chambers, 1987; Chambers and Conway, 1992). This 'sustainable rural livelihoods' approach is now widely advocated as a framework for evaluating and developing policies and programmes at the micro level, particularly in terms of poverty reduction (Ellis, 2000; Scoones, 1998). While not inconsistent with a farming systems approach, it goes beyond the focus on agricultural production technology typical of much farming systems research (Ellis and Biggs, 2001).

A livelihood is a means of earning a living. Within the livelihoods approach, 'a livelihood comprises the assets (natural, physical, human, financial, and social capital), the activities, and the access to these (mediated by institutions and social relations) that together determine the living gained by the individual or household' (Ellis, 2000, p10). This emphasis on assets, activities and access provides a convenient framework within which to develop an understanding of the complex and dynamic realities of rural households. Ellis (2000) places less emphasis on the sustainability dimension because of what he sees as its inherent vagueness, but Scoones considers that 'a livelihood is sustainable when it can cope with and recover from stresses and shocks and maintain or enhance its capabilities and assets both now and in the future, while not undermining the natural resource base' (1998, p5).

Scoones outlines the essential components of livelihoods analysis as follows:

> The key question to be asked in the analysis of sustainable livelihoods is – Given a particular *context* (of policy setting, politics, history, agroecology and socio-economic conditions), what combination of *livelihood resources* (different types of 'capital') result in the ability to follow what combination of *livelihood strategies* (agricultural intensification [or] extensification, livelihood diversification, migration) with what *outcomes*? (Scoones, 1998, p3)

Ellis (2000) gives particular emphasis to the widespread strategy of rural livelihood diversification, which he defines as 'the process by which rural households construct an increasingly diverse portfolio of activities and assets in order to survive and to improve their standard of living' (Ellis, 2000, p15). Diversification includes on-farm diversification (as measured by the range of crop, livestock and other natural resource-based activities undertaken) as well as diversification away from own-account farming to include off-farm and non-farm activities in the household's portfolio. The potential outcomes of these and other livelihood strategies are grouped by Ellis (2000) into: (1) livelihood security (income level, income stability, seasonality, risk); and (2) environmental sustainability (soil and land quality, water, forests, biodiversity).

The livelihoods framework has the advantage of placing the adoption of landcare practices and the formation of landcare groups within the context of the livelihood resources and strategies of farm households and local communities, thus explicitly linking farming systems change, rural development and natural resource management. In particular, the landcare approach can be seen as promoting sustainable rural livelihoods primarily through investment in human and social capital. While the notion of human capital is well established, social capital is a relatively new concept, hence it warrants a brief discussion here. Woolcock (1998) and

Woolcock and Narayan (2000, p226) define social capital succinctly as 'the norms and networks that enable people to act collectively'. They make the useful distinction between 'integration' or 'bonding social capital', i.e. the intra-community ties that enable poor people in a village setting to 'get by' (e.g. monitoring of property rights, labour exchange, emergency assistance, rotating savings groups, provision of communal facilities) and 'linkage' or 'bridging social capital', i.e. the extra-community networks that enable individuals and groups to tap outside sources of information, support and resources, not just enabling them to 'get by' but to 'get ahead' (e.g. links to traders and financiers, extension agents, NGOs). For development to proceed, Woolcock and Narayan (2000) suggest there is a need, not only to mobilize bonding social capital, but also to develop new linkages, or bridging social capital, opening up new opportunities for individuals and communities. The dilemma is that the formation of this latter type of social capital may well undermine the former type over time, because group success both increases demands on existing social bonds and encourages individuals within the community to pursue a greater diversity of linkages and activities. Pretty (2003) and Pretty and Ward (2001) have documented the growth of social capital as evidenced by group activity in a wide range of natural resource management sectors, including watershed management, irrigation, micro-finance, forest management, integrated pest management and farmer experimentation. The relationship between social capital and soil conservation is examined by Cramb (2004).

Sources of data

The study in Barangay Ned was based on four main sources of data: (1) project reports and statistics; (2) interviews with project staff and other key informants; (3) two questionnaire surveys; and (4) nine case studies of community landcare groups (Cramb and Culasero, 2003).

The first survey was conducted in mid-2001. The questionnaire was administered by local, trained enumerators to a stratified random sample of 313 farmers from 18 *sitio* (sub-villages), representing approximately 11 per cent of the total number of farm-households in Ned. A follow-up survey was conducted in the third quarter of 2002, using the same sample as for the 2001 survey, although only 310 of the original 313 respondents could be contacted. As well as repeating questions about the extent of adoption, the second questionnaire included questions about landcare membership and farmers' perceptions of changes in key aspects of their farming operations since the adoption of conservation measures.

Case studies of nine community landcare groups were undertaken. The groups were selected based on their relative accessibility and their reported level of activity. The case studies were based on focus group discussions and key informant interviews, conducted from August to October 2002. There were 21 participants in focus group discussions and 60 key informants, including 51 landcare members, 8 local government officials and the Landcare Facilitator for Ned. A flexible schedule of open-ended questions was used to probe the informants about their perceptions of Landcare, the history of their group, the factors promoting and inhibiting participation in the group, the development and current status of group activities, the benefits or impacts of these activities and the prospects for the future.

For the sake of brevity, only the first three sources of data are drawn upon directly in the following section. Nevertheless, the results of the case studies were broadly consistent with the findings from the project interviews and the household surveys, and help to inform the overall discussion below. A full report of the evaluation study can be found in Cramb and Culasero (2003).

Results

The context of rural livelihoods in Barangay Ned

Barangay Ned, though part of Lake Sebu Muncipality, is an atypical *barangay*, given its size and relative isolation from the municipal centre, and is on the way to becoming a municipality in its own right. It encompasses an area of over 41,000ha, comprising the Ned Settlement Area (22,000ha) and the Tasaday Reservation (19,000ha) (a forest reserve created in 1972, ostensibly to protect a small 'stone-age' tribe). In 2000 it had a total population of nearly 15,000, grouped into 30 *sitio*. The population density in the settlement area averaged around 65 persons per square km, but was higher in the northern half of the area, which had primitive road access.

Barangay Ned was established in 1962, but poor accessibility and lack of security hindered development until the early 1980s. It was originally part of the T'boli homelands but various logging concessions were granted from the 1960s and, from the 1980s, Ilonggo and other settlers moved in an acquired logged-over and other land, leaving the T'boli in the minority. In the 1990s the Department of Agrarian Reform (DAR) allocated titles to 5575 beneficiaries occupying 16,700ha, or 75 per cent of the settlement area. DAR also took responsibility for coordinating rural development in Ned, and contracted SEARCA in 1992 to implement the Ned Agro-Industrial Development Project (NAIDP), which included a component promoting conservation farming. However, support for T'boli swidden farmers was limited, leaving many of them feeling alienated from the agrarian reform process.

The climate in Ned is characterized by abundant rainfall (averaging 2200mm) uniformly distributed throughout the year, high levels of humidity and cloudiness, and moderate temperatures (averaging 21°C) due to an average elevation of 900m. Hence continuous cultivation is feasible and a wide range of crops suited to tropical and subtropical environments can be grown. The terrain is rolling to mountainous, with dominant slopes of 12–40 per cent The soils are predominantly neutral to acidic sandy-loams with a clay B horizon, of low to moderate fertility, and highly susceptible to erosion. Permanent cropland accounts for about 14,000ha

(64 per cent of the settlement area), including maize (8000ha), upland rice (2000ha), and other crops (4000ha). Grassland accounts for about 2750ha (12 per cent), and forest land (mainly degraded forest with small pockets of primary forest) for perhaps 4500ha (20 per cent).

Sitio Kibang, site of the DAR office in the northern part of Barangay Ned, is located roughly 110km from Koronadal, the capital of South Cotabato, and just over 60km from Isulan in Sultan Kudarat, the nearest major market centre (Figure 13.1). Access is via a former logging road, which becomes impassable after heavy rain. Large trucks, jeepneys and motorcycles ply this route, but transportation is limited to motorcycles when road conditions deteriorate. Maize, the main commodity produced, is sold to the few private traders in Kibang or directly to Isulan, where prices are 30–40 per cent higher. Likewise, fertilizer, the main farm input used, is purchased from local traders or in Isulan, with a similar price differential. The margins largely reflect the high transport costs. There are six functioning cooperatives in the northern *sitio*, three of which deal with farm produce as well as consumables. Traders provide short-term seasonal credit for farm inputs, at interest rates of 5–25 per cent per month, as well as for consumption needs. Larger and longer-term capital requirements are often financed by mortgaging land.

Employment is largely confined to agriculture, whether on- or off-farm; there is little non-farm employment in the *barangay*. Farm size averages just over 3ha. While most farmers have titles to their land (Certificates of Land Ownership Award or CLOA) issued by DAR in the 1990s, the tenure situation is complex and dynamic. Despite a ten-year restriction on the sale of CLOA, informal transactions have taken place and are accepted in the community. Some landowners have rented part or all of their land to tenants under a share-cropping arrangement. In other cases the land is mortgaged, with the mortgagee, the mortgagor or a tenant farming the land. Hence a significant proportion of farmers are not owner-operators.

Though shifting cultivation of rice was once dominant, by the 1990s the farming systems of both indigenous and migrant farmers involved continuous cultivation of maize and (to a lesser degree) upland rice. Use of hybrid maize seed and inorganic fertilizer was increasing. The typical cropping pattern involves two croppings per year, with upland rice or maize cultivated in the first cropping and maize in the second. Maize is mainly cultivated for sale, while upland rice is mainly for home consumption, though maize is also consumed as a staple.

Neither maize nor upland rice cultivation involved the use of soil conservation measures until NAIDP's introduction of contour hedgerows or SALT in the mid-1990s, which over 100 farmers had at least partially adopted. An on-farm research project within NAIDP (funded by ACIAR) also contributed to awareness of improved practices for steeplands. This project worked with farmer-cooperators to test a range of potentially high-value field crops (e.g. garlic, ginger and crucifers) and tree crops (e.g. coffee, mangosteen, durian and rambutan), integrated into three conservation farming options. The Mindanao Baptist Rural Life Centre (MBRLC) established a presence in some of the more remote *sitio* and also promoted adoption of SALT.

The difficult marketing environment had limited agricultural diversification. Taro, peanuts and beans were cultivated to a limited extent. Bananas were grown extensively, but only for the local market. Limited development of bunded rice fields had occurred along stream margins. Tree crops such as coffee, cocoa and fruit trees had been planted on a limited scale. Many households raised *carabao*, horses and chickens, while pigs and goats were raised by a smaller number of households.

Barangay Ned thus provided a formidable challenge for the Landcare Programme. On the one hand, the site imposed severe limitations. The rural landscape had undergone rapid transformation due to the combined effects of shifting cultivation, logging and land clearance, exposing the soil to severe degradation. Increasing population density and isolation from markets dictated a farming system based on continuous cultivation of cereals, especially maize, which served as the only cash crop and increasingly as a substitute staple for rice. Farmers were poor, with little education, mostly lacking in experience of this upland environment, and not highly organized, relying on face-to-face contacts in small clan groupings and local neighbourhoods for support. Though aware of soil erosion, they lacked the knowledge and means to combat it. On the other hand, the site's considerable agricultural potential, the dynamism characteristic of a frontier settler society, and the relative lack of previous intervention by agencies providing agricultural research and extension, meant the Landcare Programme could expect to generate a positive response among farmers.

The Ned Landcare Programme

The Landcare Programme was well placed to build on the conservation farming component of the NAIDP and the on-farm research of the earlier ACIAR project. As the implementing agency for both projects, SEARCA could provide institutional continuity for the Landcare Programme, including first-hand awareness of the successes and failures of the previous efforts. Most important, the Landcare Facilitator had five years experience working for the ACIAR on-farm research project, developing and testing new farming practices with farmers and researchers. Thus the legacy of the two previous projects was that: (1) the Facilitator had considerable locally validated technical expertise, as well as credibility in the farming community; (2) there was already a pool of farmers around Kibang who had adopted contour hedgerows, experimented with alternative annual and perennial crops, and learned the benefits of working and learning together in small groups; and (3) there was experience in working with part-time, paid farmer-trainers.

As part of the larger ACIAR Landcare Project, the Ned Landcare Programme brought two new emphases – the promotion of NVS as a simpler, lower-cost alternative to legume hedgerows and the formation of community landcare groups (as well as a Landcare Association and Landcare Advisory Group). Apart from the emphasis on groups, the Landcare Programme was primarily a programme of extension and training in technical aspects of farm development, including conservation measures and the establishment of new crops. Initially the Programme emphasized the 'high-value' field crops that the earlier ACIAR project had tested, but as problems of pest management and marketing emerged, and as previously planted fruit trees began to bear, the emphasis shifted to perennials – first coffee, then increasingly durian and other fruit trees. Farmers' interest in acquiring planting materials and technical knowledge for crop diversification was used as the 'entry point' to encourage both adoption of conservation measures and membership of landcare groups. This strategy was highly successful – many landcare groups were formed and most landcare members established contour barriers on their farms.

There was rapid formation of landcare groups over the first three years of the Landcare Programme, but at a declining rate (Figure 13.2). By 2002 there were 39 groups with 366 members, roughly 10 per cent of farm households in Ned. Whereas the Landcare Facilitator had initiated most of the groups formed in the first 12–18 months of the project, the appointment of part-time farmer-facilitators in mid-2000 meant that they took most responsibility for forming and supporting groups from that time, working as intermediaries between the Landcare Facilitator and the groups. Farmers also formed groups on their own, and in some cases helped neighbouring groups to get established. The growth in total landcare membership followed a similar path to the total number of groups, meaning there was no overall growth in the size of groups. Larger *sitio*-level groups tended to break up into smaller *purok*-level groups (a *purok* is a hamlet), reducing the costs to members of participation in meetings and group work, though some of these groups lacked leadership and lost momentum. Security problems in the south of the *barangay* disrupted some groups.

There was a steady rate of adoption of contour barriers by landcare group members – about 50ha a year. In most cases group activities (such as meetings and group work) declined once most members had been helped to implement contour

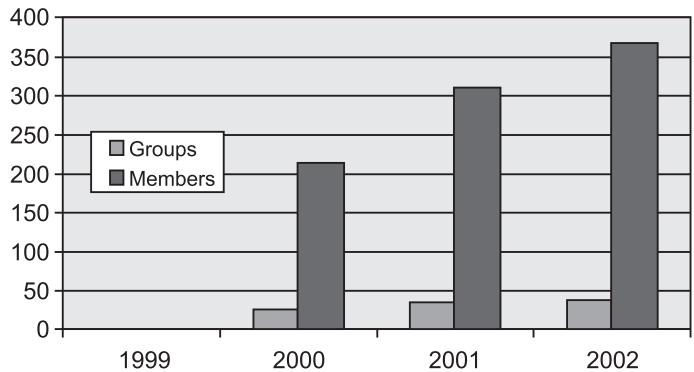

Figure 13.2 *Number of landcare groups and members in Ned*

barriers. The ongoing interest in fruit tree production was largely met through establishment of individual rather than group nurseries, though landcare membership provided access to group training events and assistance from facilitators. However, a few groups had developed sufficient momentum to move beyond the initial focus on conservation farming, developing their own projects to meet the needs of members, e.g. for cheaper farm inputs and medicines.

The training provided to landcare groups appeared to decline over time, which may have been one reason for the general decline in group activity. The training was mainly technical, dealing with contour farming, vegetable production, and propagation and establishment of perennials, though there was an increase in the number of training events dealing with group organization and facilitation.

The Ned Landcare Association (NLCA), formed in 1999, comprised the leader of each landcare group as well as the Landcare Facilitator and staff of DAR and MBRLC. It was an active association, no doubt helped by the involvement of the Facilitator. It met quarterly to exchange information, planned and organized *barangay*-wide landcare activities and took initiatives on behalf of the landcare groups, securing grants and loans for nursery materials and seeds. A Landcare Advisory Group was established but probably added little to the informal linkages developed by the Landcare Facilitator.

Linkages with local government units (LGU) were relatively weak. Officers of the Barangay Council gave little attention to Landcare, though more recently there were moves by landcare leaders to get representation on the council, and the Landcare Association had secured a grant from the council. As Barangay Ned was remote from the municipal LGU, the mayor and other officials knew little about the Landcare Programme. Other institutions provided minimal support, though the MBRLC collaborated closely with the Landcare Programme.

Impacts of the programme

Based on the household survey, over a third of farmers in Barangay Ned (38 per cent) had adopted conservation measures (vegetative barriers, physical barriers and/or tree planting), affecting about 16 per cent of the total cultivated area (Table 13.1). As conservation measures were adopted preferentially on steeply sloping land, the impact of adoption on the catchment as a whole would have been greater than the figure of 16 per cent suggests. In most cases the adopted measures were considered effective in controlling erosion and had been maintained or expanded. Further expansion of vegetative or physical barriers on adopters' farms was slow, but expansion of tree planting, especially fruit trees, was underway. There was evidence that diffusion of conservation practices to additional farmers was still occurring.

The primary reasons for adopting (or planning to adopt) conservation measures were to control erosion and restore soil fertility. Prospective adopters were also hoping to receive benefits from the Landcare Programme, especially fruit tree seedlings. The main reasons given for not yet adopting were the lack of time or interest, the perceived difficulty of maintaining contour hedgerows and lack of ownership rights to the land.

A statistical comparison between adopters and non-adopters suggested that age, education, gender, place of origin, farming experience in the region, availability of family labour for farm work, engagement in off-farm employment and accessibility to the market centre and to extension personnel were not in themselves major factors in the adoption decision (Table 13.2). Non-adopters seemed as *aware of soil erosion* as adopters. Farmers with larger farms who owned part or all of their farms were significantly more likely to be adopters (Table 13.2), though the relationship between farm size, tenure and adoption was complex and dynamic. The main difference between adopters and non-adopters was that more of the former had acquired *knowledge of conservation measures*, mostly within the previous eight years (Table 13.3; Figure 13.3). This had occurred primarily through practical, farmer-led training events arranged by SEARCA and other agencies (both before and during the Landcare Programme), and secondarily through observation of neighbour's farms where conservation measures had been implemented (Table 13.4).

Farmers' perceptions of trends within their farming operations gave some insight into the impact of adopting conservation measures. Adoption was associated with relatively favourable net trends in maize yield (though not farming operations gave some insight into the necessarily in total maize output), soil loss, soil impact of adopting conservation measures, fertility, use of fertilizer, forage supply and the planting of fruit trees. However, adoption was also associated with an increased workload for men and did not yet result in a clear trend in farm cash income.

The Landcare Programme was widely known and about 25 per cent of the farmers surveyed were members of a landcare group. Landcare membership was positively associated with adoption (51 per cent of adopters were landcare members compared with only 8 per cent of non-adopters; Table 13.5). However, membership in itself was neither necessary nor sufficient to induce adoption of

conservation practices – almost half the adopters were not landcare members and over 20 per cent of landcare members were not adopters. This suggests that extension and training, and observation of neighbouring farms, were more influential in encouraging farmers to adopt conservation measures than landcare membership per se. Landcare members were more likely to have participated in formal training and cross-farm visits, however, in some cases this would have preceded rather than followed the formation or joining of a landcare group.

The main reasons given for joining a landcare group were economic – to learn about farm technologies and receive benefits such as tree seedlings. Secondary reasons were social in nature – to have a group of friends and attend meetings. Where problems were encountered they centred on misunderstandings, poor communication, lack of participation and disunity within the group, all related to lack of leadership or regular contact with a facilitator. In some cases this had led to members dropping out or the group disbanding. Non-members generally felt they were too busy to join or that there was no point as they were not landowners.

Discussion

In this section, the facts of the Landcare Programme in Ned as summarized above are analysed and interpreted explicitly from a sustainable livelihoods perspective. At the outset the farming community in Ned was severely lacking in access to livelihood resources, including physical, financial, human and social capital (especially bridging social capital), and as a consequence was rapidly depleting its natural capital. The dominant livelihood strategies from the early 1980s had been, first, migration into the Ned Settlement Area, followed by 'extensification' through land clearing, then intensification of the farming system, with very little opportunity for on- or off-farm diversification. For indigenous farmers, the opening up of their lands to logging and settlement had also necessitated a strategy of agricultural intensification. The main institution mediating access to resources had been DAR, allocating equal-sized lots to agrarian reform beneficiaries. However, informal land and capital markets developed, leading to a rapidly growing inequality in access to land. The result was differential livelihood outcomes for different classes of farm household, especially owners and tenants. Though outcomes varied, for many households livelihood security was not assured and environmental sustainability was also under threat. Hence there was a ready interest in the Landcare Programme's twin emphasis on soil conservation and developing new livelihood activities.

Building on previous project experience in Ned, the Landcare Programme became an important new element in the farmers' institutional environment, particularly in the form of the resident Landcare Facilitator, whose commitment, skills and local reputation were crucial to the Programme's success. As described above, the Programme targeted: (1) the training of farmers in soil conservation (especially NVS) and agroforestry, with a high degree of involvement of farmer-adopters in the training process; and (2) the formation of landcare groups, linked in a landcare association. In other words, the Programme focused on building human capital (in the form of knowledge and skills to implement soil conservation measures and other farm improvements) and social capital (in the form of improved communication and cooperation through local landcare groups, linked in a barangay-wide landcare association). The Programme provided little in the form of financial capital, though planting materials were an important input. In evaluating the Programme it is important to assess the relative importance of these different forms of capital investment and their interrelationships.

The evidence suggests that the enhancement of human capital was the key to the rapid adoption of soil conservation measures. While adoption was positively associated with farm size and ownership, the main distinguishing feature of adopters was their exposure to training. The practical, farmer-to-farmer nature of this training was the key to its effectiveness, combined with the relative simplicity and effectiveness of the contour farming technology promoted. While soil conservation was a primary focus of landcare training activities, farmers were at least as interested in accessing new livelihood opportunities, principally through planting fruit and timber species in their contoured farms. Linking adoption of conservation measures to these new opportunities was an effective strategy.

On the face of it, the building of social capital was of secondary importance. Though formation of landcare groups assisted members to learn about and implement conservation practices, many adopters were not landcare members and not all landcare members were adopters. Those farmers who joined landcare groups did so primarily to access training, technical advice and assistance (e.g. with planting materials), that is, to augment their human and, to some degree, their financial capital. While a few landcare groups developed a dynamism of their own, identifying new needs and organizing activities to meet those needs, most groups became less active once members had been assisted to contour their farms. Some groups disbanded because of internal conflicts or external changes. The personal qualities of the group leader were a key factor in maintaining and expanding the group's activities, along with the degree of contact and support from landcare facilitators (including farmer-facilitators).

Nevertheless, some members of apparently defunct groups suggested that because group members were close neighbours or kin, they could readily reactivate the group if there was a perceived need, suggesting that their social capital had not been eroded and, in fact, existed independently of the formation or demise of their landcare group. Moreover, the Landcare Association, working on behalf of the local groups and in conjunction with the Landcare Facilitator, was influential in organizing training and accessing outside resources, e.g. from local and provincial government, as well as bringing together and supporting local group leaders who would otherwise have been very isolated (in particular, farm leaders from remote T'boli settlements).

The key to understanding these developments lies in the distinction between bonding and bridging social capital, mentioned above. Typically, there was already a high level of bonding social capital in the local communities where landcare groups were formed – hence the ease of group formation. Forming a landcare group was a reflection of this initial stock of social capital rather than a means of generating greater local-level integration. For example, implementing contour barriers through small work groups was a natural extension of the system of labour exchange already in place in both indigenous and immigrant communities. The persistence of a group both reflected and reinforced the degree of trust and cooperation in these pre-existing social bonds.

However, forming or joining a landcare group also meant linking to a much wider network than provided by the local community. Hence it can be viewed primarily as an investment in bridging social capital. The bridges included horizontal linkages with progressive farmers in other localities through the municipal-wide landcare association, as well as vertical linkages with SEARCA and other outside agencies. (Some writers now make a conceptual distinction between such horizontal extra-community ties, which they term 'bridging social capital', and vertical ties, termed 'linking social capital'.) This dimension of landcare clearly augmented the stock of social capital in ways that provided significant benefits, both to members and non-members of community landcare groups (note that many farmers learned the new conservation practices directly from their neighbours). Hence the decline of local group activity often merely reflected a declining immediate need for that kind of activity (contouring, nursery establishment) but not a declining interest in the bridging social capital provided by the landcare network.

In some respects, the development of this bridging social capital actually undermined the bonding social capital encapsulated in the local groups, as predicted by Woolcock (1998). In particular, as members gained knowledge and experience in nursery management through the communal landcare nurseries, some preferred to develop private nurseries and pursue commercial outlets for their planting materials (a phenomenon that had occurred earlier in the landcare sites at Claveria and Lantapan). However, such individuals still valued the links to the Landcare Facilitator and the Association.

Ongoing investment to maintain and expand the stock of bridging social capital was clearly needed. In particular, the support of LGUs at the *barangay* and municipal levels that was evident in the Claveria Landcare Programme was not found to the same degree in Ned. This did not appear to have hindered landcare activities in the short term and may in fact have encouraged the Association leaders to organize, including the mobilization of political support. However, the presence of a strong facilitating institution (SEARCA) had been essential, offsetting the immediate need for partnership with LGUs. In the longer term, stronger links with an array of government and non-government agencies would be needed to sustain the Landcare Programme in Ned.

It can be concluded that the Landcare Programme had made a significant investment in livelihood resources, notably human and social capital, with the investment in social capital providing the necessary linkages for the adaptive research and farmer-to-farmer training activities that led to the growth of human capital. However, the outcomes of the Landcare Programme for both livelihood security and environmental sustainability were not as easy to establish. There was clear evidence that adoption of the recommended conservation practices had a significant impact on reducing soil erosion, hence on maintaining farmers' natural capital. The catchment-wide impacts remain to be investigated. Although these wider impacts are likely to have been positive, with only 16 per cent of the total cultivated area under conservation measures, the total impact is unclear. The impact on farm incomes was not obvious in the short term and was likely to be primarily a function of the changed cropping practices implemented on the contoured farms, that is, the diversification of livelihood activities. Farm budgets suggest that the expansion of tree crops will ultimately lead to a quantum jump in farm incomes, relative to merely maintaining maize yields. The full realization of these livelihood benefits will depend to a large degree on continuing investment in physical capital in the form of improved transport infrastructure, something that is beyond the scope of the Landcare Programme.

Conclusion

The study found that the Landcare Programme in Barangay Ned has been associated with rapid adoption of simple conservation farming practices, especially natural vegetative strips, and the rapid formation of local landcare groups and a *barangay*-wide landcare association. Such rapid adoption has not often been observed in the Philippine uplands. Using a sustainable rural livelihoods framework for the evaluation study helped to place these phenomena within the context of the agroecological and institutional changes that had been taking place in the preceding two decades, and the evolving livelihood strategies of rural households in Ned, particularly their interest in on-farm diversification to augment their meagre cash incomes. The most important effect of the Landcare Programme was to enhance the human capital of the farming population through practical, farmer-led training and extension, enabling farmers to incorporate soil conservation and agroforestry technologies in their farming systems, with desirable outcomes both for livelihood security and environmental sustainability. The social capital formed through the Programme, particularly the bridging social capital in the form of the Ned Landcare Association and its networks, was crucial to the growth in human capital. Nevertheless, ongoing investment was required to maintain and expand the stock of social capital for the longer term success of the Programme, including its capacity to be scaled up to embrace other localities.

The larger message from the study is that the promotion of conservation farming systems in fragile and impoverished upland environments requires an approach that embraces sustainable rural livelihoods, both for farm households and local communities, rather than narrowly focusing on the transfer of technology or the imposition of environmental regulations. While the availability of simple, well-adapted conservation practices is a key starting point, programme interventions such as the Landcare Programme that invest in human and social capital – thus building the capacity of farmers and farming communities to identify and pursue sustainable livelihood strategies – are essential to achieving the twin goals of rural development and environmental conservation. However, such farmer-led approaches still require ongoing partnerships with adequately resourced facilitating agencies, whether local government units or non-government organizations, or (preferably) both.

Conserving Communities

Wendell Berry

In October of 1993, the *New York Times* announced that the United States Census Bureau would 'no longer count the number of Americans who live on farms'. In explaining the decision, the *Times* provided some figures as troubling as they were unsurprising. Between 1910 and 1920, we had 32 million farmers living on farms – about a third of our population. By 1950, this population had declined, but our farm population was still 23 million. By 1991, the number was only 4.6 million, less than 2 per cent of the national population. That is, our farm population had declined by an average of almost half a million people a year for 41 years. Also, by 1991, 32 per cent of our farm managers and 86 per cent of our farm workers did *not* live on the land they farmed.

These figures describe a catastrophe that is now virtually complete. They announce that we no longer have an agricultural class that is, or that can require itself to be, recognized by the government; we no longer have a 'farm vote' that is going to be of much concern to politicians. American farmers, who over the years have wondered whether or not they counted, may now put their minds at rest: they do not count. They have become statistically insignificant.

We must not fail to appreciate that this statistical insignificance of farmers is the successful outcome of a national purpose and a national programme. It is the result of great effort and of principles rigorously applied. It has been achieved with the help of expensive advice from university and government experts, by the tireless agitation and exertion of the agribusiness corporations, and by the renowned advantages of competition – of our farmers among themselves and with farmers of other countries. As a result, millions of country people have been liberated from farming, landownership, self-employment and other idiocies of rural life.

But what has happened to our agricultural communities is not exceptional any more than it is accidental. This is simply the way a large, exploitive, absentee economy works. For example, here is a *New York Times* News Service report on 'rape-and-run' logging in Montana:

Reprinted from Berry W. 1996. Conserving communities. In Vitek W and Jackson W (eds) *Rooted in the Land: Essays on Community and Place*. Yale University Press, New Haven and London. pp76–84.

> Throughout the 1980s, the Champion International Corp. went on a tree-cutting binge in Montana, leveling entire forests at a rate that had not been seen since the cut-and-run logging days of the last century.
>
> Now the hangover has arrived. After liquidating much of its valuable timber in the Big Sky country, Champion is quitting Montana, leaving behind hundreds of unemployed mill workers, towns staggered by despair and more than 1,000 square miles of heavily logged land.

The article goes on to speak of the revival of 'a century-old complaint about large, distant corporations exploiting Montana for its natural resources and then leaving after the land is exhausted'. And it quotes a Champion spokesman, Tucker Hill, who said: 'We are very sympathetic to those people and very sad. But I don't think you can hold a company's feet to the fire for everything they did over the last twenty years.'

If you doubt that exhaustion is the calculated result of such economic enterprise, you might consider the example of the mountain counties of eastern Kentucky from which, over the last three-quarters of a century, enormous wealth has been extracted by the coal companies, leaving the land wrecked and the people poor.

The same kind of thing is now happening in banking. In the county next to mine an independent local bank was recently taken over by a large out-of-state bank. Suddenly some of the local farmers and small-business people, who had been borrowing money from that bank for 20 years and whose credit records were good, were refused credit because they did not meet the requirements of a computer in a distant city. Old and once-valued customers now find that they are known by category rather than character. The directors and officers of the large bank clearly have reduced their economic thinking to one very simple question: 'Would we rather make one big loan or many small ones?' Or to put it only a little differently: 'Would we rather support one larger enterprise or many small ones?' And they have chosen the large over the small.

This economic prejudice against the small has, of course, done immense damage for a long time to small or family-sized businesses in city and country alike. But this prejudice has often overlapped with an industrial prejudice against anything rural and against the land itself, and this prejudice has resulted in damages that are not only extensive but also long-lasting or permanent.

As we all know, we have much to answer for in our use of this continent from the beginning, but in the last half-century we have added to our desecrations of nature a deliberate destruction of our rural communities. The statistics I cited at the beginning are incontrovertible evidence of this. But so is the condition of our farms and forests and rural towns. If you have eyes to see, you can see that there is a limit beyond which machines and chemicals cannot replace people; there is a limit beyond which mechanical or economic efficiency cannot replace care.

I am talking here about the common experience, the common fate, of rural communities in our country for a long time. It has also been, and it will increasingly be, the common fate of rural communities in other countries. The message is plain enough, and we have ignored it for too long: the great, centralized economic entities of our time do not come into rural places in order to improve them by 'creating jobs'. They come to take as much of value as they can take, as cheaply and as quickly as they can take it. They are interested in 'job creation' only so long as the jobs can be done more cheaply by humans than by machines. They are not interested in the good health – economic or natural or human – of any place on this Earth. And if you should undertake to appeal or complain to one of these great corporations on behalf of your community, you would discover something most remarkable: you would find that these organizations are organized expressly for the evasion of responsibility. They are structures in which, as my brother says, 'the buck never stops'. The buck is processed up the hierarchy until finally it is passed to 'the shareholders', who characteristically are too widely dispersed, too poorly informed and too unconcerned to be responsible for anything. The ideal of the modern corporation is to be (in terms of its own advantage) anywhere and (in terms of local accountability) nowhere. The message to country people, in other words, is this: Don't expect favours from your enemies.

And that message has a corollary that is just as plain and just as much ignored: the governmental and educational institutions from which rural people should by right have received help have not helped. Rather than striving to preserve the rural communities and economies and an adequate rural population, these institutions have consistently aided, abetted and justified the destruction of every part of rural life. They have eagerly served the superstition that all technological innovation is good. They have said repeatedly that the failure of farm families, rural businesses and rural communities is merely the result of progress and efficiency and is good for everybody.

We are now pretty obviously facing the possibility of a world that the supranational corporations, and the governments and educational systems that serve them, will control entirely for their own enrichment – and, incidentally and inescapably, for the impoverishment of all the rest of us. This will be a world in which the cultures that preserve nature and rural life will simply be disallowed. It will be, as our experience already suggests, a postagricultural world. But as we now begin to see, you cannot have a postagricultural world that is not also postdemocratic, postreligious, postnatural – in other words, it will be posthuman, contrary to the best that we have meant by 'humanity'.

In their dealings with the countryside and its people, the promotors of the so-called global economy are following a set of principles that can be stated as follows. They believe that a farm or a forest is or ought to be the same as a factory; that care is only minimally necessary in the use of the land; that affection is not necessary at all; that for all practical purposes a machine is as good as a human; that the industrial standards of production, efficiency and profitability are the only standards that are necessary; that the topsoil is lifeless and inert; that soil biology is safely replaceable by soil chemistry; that the nature or ecology of any given place is irrelevant to the use of it; that there is no value in human community or neighbourhood; and that technological innovation will produce only benign results.

These people see nothing odd or difficult about unlimited economic growth or unlimited consumption in a limited world. They believe that knowledge is property and is power, and that it ought to be. They believe that education is job training. They think that the summit of human achievement is a high-paying job that involves no work. Their public boast is that they are making a society in which everybody will be a 'winner' – but their private aim has been to reduce radically the number of people who, by the measure of our historical ideals, might be thought successful: the independent, the self-employed, the owners of small businesses or small usable properties, those who work at home.

The argument for joining the new international trade agreements has been that there is going to be a one-world economy, and we must participate or be left behind – though, obviously, the existence of a one-world economy depends on the willingness of all the world to join. The theory is that under the rule of international, supposedly free, trade products will naturally flow from the places where they can be best produced to the places where they are most needed. This theory assumes the long-term safety and sustainability of massive international transport, for which there are no guarantees, just as there are no guarantees that products will be produced in the best way or to the advantage of the workers who produce them or that they will reach or can be afforded by the people who need them.

There are other unanswered questions about the global economy, two of which are paramount: How can any nation or region justify the destruction of a local productive capacity for the sake of foreign trade? and How can people who have demonstrated their inability to run national economies without inflation, usury, unemployment and ecological devastation now claim that they can do a better job in running a global economy? American agriculture has demonstrated by its own ruination that you cannot solve economic problems just by increasing scale and, moreover, that increasing scale is almost certain to cause other problems – ecological, social and cultural.

We can't go on too much longer, maybe, without considering the likelihood that we humans are not intelligent enough to work on the scale to which we have been tempted by our technological abilities. Some such recognition is undoubtedly implicit in American conservatives' long-standing objection to a big central government. And so it has been odd to see many of these same conservatives pushing for the establishment of a supranational economy that would inevitably function as a government far bigger and more centralized than any dreamed of before. Long experience has made it clear – as we might say to the liberals – that to be free we must limit the size of government and we must have some sort of home rule. But it is just as clear – as we might say to the conservatives – that it is foolish to complain about big government if we do not do everything we can to support strong local communities and strong community economies.

But in helping us to confront, understand and oppose the principles of the global economy, the old political alignments have become virtually useless. Communists and capitalists are alike in their contempt for country people, country life and country places. They have exploited the countryside with equal greed and disregard. They are alike even in their plea that it is right to damage the present in order to make 'a better future'.

The dialogue of Democrats and Republicans or of liberals and conservatives is likewise useless to us. Neither party is interested in farmers or in farming or in the good care of the land or in the quality of food. Nor are they interested in taking the best care of our forests. The leaders of these parties are equally subservient to the supranational corporations. Of this the North American Free Trade Agreement and the new revisions to the General Agreement on Tariffs and Trade are proof.

Moreover, the old opposition of country and city, which was never useful, is now more useless than ever. It is, in fact, damaging to everybody involved, as is the opposition of producers and consumers. These are not differences but divisions that ought not to exist because they are to a considerable extent artificial. The so-called urban economy had been just as hard on urban communities as it has been on rural ones.

All these conventional affiliations are now meaningless, useful only to those in a position to profit from public bewilderment. A new political scheme of opposed parties, however, is beginning to take form. This is essentially a two-party system, and it divides over the fundamental issue of community. One of these parties holds that community has no value; the other holds that it does. One is the party of the global economy; the other I would call simply the party of local community. The global party is large, though not populous, immensely powerful and wealthy, self-aware, purposeful and tightly organized. The community party is only now becoming aware of itself; it is widely scattered, highly diverse, small though potentially numerous, weak though latently powerful and poor though by no means without resources.

We know pretty well the makeup of the party of the global economy, but who are the members of the party of local community? They are people who take a generous and neighbourly view of self-preservation; they do not believe that they can survive and flourish by the rule of dog eat dog; they do not believe that they can succeed by defeating or destroying or selling or using up everything but themselves. They doubt that good solutions can be produced by violence. They want to preserve the precious things of nature and of human culture and pass them on to their children. They want the world's fields and forests to be productive; they do not want them to be destroyed for the sake of production. They know you cannot be a democrat (small *d*) or a conservationist and at the same time a proponent of the supranational corporate economy. They believe – they know from their experience – that the neighbourhood, the local community, is the proper place and frame of reference for responsible work. They see that no commonwealth or community of interest can be defined by greed. They know that things connect – that farming, for example, is connected to nature, and food to farming, and health to food – and they want to preserve the connections. They know that a healthy local community cannot be replaced by a market or an entertainment industry or an information highway. They know that contrary to all the unmeaning and unmeant political talk about 'job creation', work ought not to be merely a bone thrown to the otherwise unemployed. They know that work ought to be necessary; it ought to be good; it ought to be satisfying and dignifying to the people who do it, and genuinely useful and pleasing to the people for whom it is done.

The party of local community, then, is a real party with a real platform and an agenda of real and doable work. And it has, we might add, a respectable history in the hundreds of efforts, over several decades, to preserve local nature or local health or to sell local products to local consumers. Now such efforts appear to be coming into their own, attracting interest and energy in a way they have not done before. People are seeing more clearly all the time the connections between conservation and economics. They are seeing that a community's health is largely determined by the way it makes its living.

The natural membership of the community party consists of small farmers, ranchers and market gardeners, worried consumers, owners and employees of small shops, stores, community banks and other small businesses, self-employed people, religious people and conservationists. The aims of this party really are only two: the preservation of ecological diversity and integrity, and the renewal, on sound cultural and ecological principles, of local economies and local communities.

So now we must ask how a sustainable local community (which is to say a sustainable local economy) might function. I am going to suggest a set of rules that I think such a community would have to follow. And I hasten to say that I do not consider these rules to be predictions; I am not interested in foretelling the future. If these rules have any validity, it is because they apply now.

If the members of a local community want their community to cohere, to flourish and to last, these are some things they would do:

1 Always ask of any proposed change or innovation: What will this do to our community? How will this affect our common wealth?
2 Always include local nature – the land, the water, the air, the native creatures – within the membership of the community.
3 Always ask how local needs might be supplied from local sources, including the mutual help of neighbours.
4 Always supply local needs *first*. (And only then think of exporting, first to nearby cities and then to others.)
5 Understand the unsoundness of the industrial doctrine of 'labour saving' if that implies poor work, unemployment or any kind of pollution or contamination.
6 Develop properly scaled value-adding industries for local products to ensure that the community does not become merely a colony of the national or global economy.
7 Develop small-scale industries and businesses to support the local farm and/or forest economy.
8 Strive to produce as much of the community's own energy as possible.
9 Strive to increase earnings (in whatever form) within the community and decrease expenditures outside the community.

10 Make sure that money paid into the local economy circulates within the community for as long as possible before it is paid out.
11 Make the community able to invest in itself by maintaining its properties, keeping itself clean (without dirtying some other place), caring for its old people, teaching its children.
12 See that the old and the young take care of one another. The young must learn from the old, not necessarily and not always in school. There must be no institutionalized ‘child care’ and ‘homes for the aged’. The community knows and remembers itself by the association of old and young.
13 Account for costs now conventionally hidden or ‘externalized’. Whenever possible, these costs must be debited against monetary income.
14 Look into the possible uses of local currency, community-funded loan programmes, systems of barter and the like.
15 Always be aware of the economic value of neighbourly acts. In our time the costs of living are greatly increased by the loss of neighbourhood, leaving people to face their calamities alone.
16 As a rural community, always be acquainted with, and complexly connected with, community-minded people in nearby towns and cities.
17 Formulate an economy that will always be more cooperative than competitive, for a sustainable rural economy is dependent on urban consumers loyal to local products.

These rules are derived from Western political and religious traditions, from the promptings of ecologists and certain agriculturists and from common sense. They may seem radical, but only because the modern national and global economies have been formed in almost perfect disregard of community and ecological interests. A community economy is not an economy in which well-placed persons can make a ‘killing’. It is not a killer economy. It is an economy whose aim is generosity and a well-distributed and safeguarded abundance. If it seems unusual to hope and work for such an economy, then we must remember that a willingness to put the community ahead of profit is hardly unprecedented among community businesspeople and local banks.

How might we begin to build a decentralized system of durable local economies? Gradually, I hope. We have had enough of violent or sudden changes imposed by predatory interests outside our communities. In many places, the obvious way to begin the work I am talking about is with the development of a local food economy. Such a start is attractive because it does not have to be big or costly, it requires nobody’s permission and it can ultimately involve everybody. It does not require us to beg for mercy from our exploiters or to look for help where consistently we have failed to find it. By ‘local food economy’ I mean simply an economy in which local consumers buy as much of their food as possible from local producers and in which local producers produce as much as they can for the local market.

Several conditions now favour the growth of local food economies. On the one hand, the costs associated with our present highly centralized food system are going to increase. Growers in the Central Valley of California, for example, can no longer depend on an unlimited supply of cheap water for irrigation. Transportation costs can only go up. Biotechnology, variety patenting and other agribusiness innovations are intended not to help farmers or consumers but to extend and prolong corporate control of the food economy; they will increase the cost of food, both economically and ecologically.

On the other hand, consumers are increasingly worried about the quality and purity of their food, and so they would like to buy from responsible growers close to home. They would like to know where their food comes from and how it is produced. They are increasingly aware that the larger and more centralized the food economy becomes, the more vulnerable it will be to natural or economic catastrophe, to political or military disruption and to bad agricultural practice.

For all these reasons, and others, we need urgently to develop local food economies wherever they are possible. Local food economies would improve the quality of food. They would increase consumer influence over production; consumers would become participatory members in their own food economy. They would help to ensure a sustainable, dependable supply of food. By reducing some of the costs associated with long supply lines and large corporate suppliers (such as packaging, transportation and advertising), they would reduce the cost of food at the same time that they would increase income to growers. They would tend to improve farming practices and increase employment in agriculture. They would tend to reduce the size of farms and increase the number of owners.

Of course, no food economy can be, or ought to be, *only* local. But the orientation of agriculture to local needs, local possibilities and local limits is indispensable to the health of both land and people, and undoubtedly to the health of democratic liberties as well.

For many of the same reasons, we need also to develop local forest economies, of which the aim would be the survival and enduring good health of both our forests and their dependent local communities. We need to preserve the native diversity of our forests as we use them. As in agriculture, we need local, small-scale, non-polluting industries (sawmills, woodworking shops and so on) to add value to local forest products, as well as local supporting industries for the local forest economy.

Just as support for sustainable agriculture should come most logically from consumers who consciously wish to keep eating, so support for sustainable forestry might logically come from loggers, mill workers and other employees of the forest economy who consciously wish to keep working. But *many* people have a direct interest in the good use of our forests: farmers and ranchers with woodlots, all who depend on the good health of forested watersheds, the makers of wood products, conservationists and others.

What we have before us, if we want our communities to survive, is the building of an adversary economy, a system of local or community economies within, and to protect against, the would-be global economy. To do this, we must somehow learn to reverse the flow of the siphon that has for so long been drawing resources, money, talent and people out of our countryside with very little if any return, and often with a return only of pollution, impoverishment and ruin. We must figure out new ways to fund, at affordable rates, the development of healthy local economies. We must find ways to suggest economically – for finally no other suggestion will be effective – that the work, the talents and the interest of our young people are needed at home.

Our whole society has much to gain from the development of local land-based economies. They would carry us far toward the ecological and cultural ideal of local adaptation. They would encourage the formation of adequate local cultures (and this would be authentic multiculturalism). They would introduce into agriculture and forestry a sort of spontaneous and natural quality control, for neither consumers nor workers would want to see the local economy destroy itself by abusing or exhausting its sources. And they would complete at last the task of gaining freedom from colonial economics, begun by our ancestors more than 200 years ago.

Becoming an Agroecologist Through Action Education

Geir Lieblein, Edvin Østergaard and Charles Francis

Introduction

Education in agroecology (Francis et al, 2003), agricultural systems and sustainable agriculture can provide students with a broad curriculum that deals with the interaction among production, economic, environmental and social dimensions of farming and food systems. Courses in agroecology and organic farming are becoming more prevalent on university campuses in the Nordic region, Europe, US and elsewhere (Sriskandarajah et al, 2005). Yet we observe that in most programmes and courses the teaching methods have departed little from a strong emphasis on transmitting information through lectures, some discussion and library readings, and periodic trips to farms that often turn into lectures in the field.

The predominance of lectures and narrowly focused courses are used in many agriculture and food system curricula as an accepted and even expected approach to education that fits into the comfort zones of both teacher and student. The majority of university teachers are specialists in research disciplines in science where they did graduate study, and few have experienced formal courses in educational history and theory. They are unfamiliar with the tenets of John Dewey's admonition that learning should not be authoritarian, but should begin with the experience of the individual students (Dewey, 1916).

Even teachers in agriculture who are not versed in the education literature will identify with Mezirow's (2000) thesis that the way in which we build understanding around a specific context often reflects our initial assumptions. We have more difficulty dealing with his conclusion that there are no fixed truths nor definitive knowledge, though a growing appreciation of the complexity of farming and food systems is leading us as agricultural scientists in that direction. Mezirow's transformation theory helps us understand how important it is to become aware of our assumptions and expectations, and to adjust those to the students or farmers we

Reprinted from Lieblein G, Østergaard E and Francis C. 2004. Becoming an agroecologist through action education, *Int. J. Agric. Sust.* 2(3), 147–153, Earthscan, London.

work with in the educational arena. Mezirow emphasized the need to critically reflect on the assumptions and beliefs that shape practice, and proposed that such reflection can transform our knowledge. We can then appreciate how these assumptions can filter our experiences as well as our awareness and understanding of what we observe, much as Kuhn (1962) describes the adherence to a dominant paradigm in each field of study.

Boud et al (1993) emphasize the importance of how learning occurs in many places, and how this shapes our total experience and our lives. We learn to deal with complexities of systems, our own and others' personal commitments and the emotions and feelings that help shape each 'learning landscape'. In line with John Dewey, Boud and colleagues emphasize that (1) experience is the foundation for learning, (2) learners actively construct their experience, (3) the process is inherently holistic, (4) learning is socially and culturally constructed, and (5) the entire educational process is strongly influenced by the socio-emotional context in which it occurs.

We have taken these lessons to heart in design of the Nordic region programme in Agroecology (Francis et al, 2001; Lieblein et al, 1999, 2001a, 2001b) and an Agroecosystems Analysis course in the US Midwest (Wiedenhoeft et al, 2003) that both feature action and participation-based learning. An allied term used for education that moves students onto the farm and into the community to deal with people and challenges in real-life situations is 'service learning' (Benson and Harkavy, 2000; Pollack, 1999), where students go beyond observation and become proactive in community change.

In the Nordic and Midwest programmes, teachers and students share the responsibility for learning. Faculty act as guides or learning leaders to organize an educational environment or 'learning landscape' where it is conducive and safe to explore and discover. The field is broadened from focus on the teacher to also encompass the students and their experiences. Maximum attention is placed on the process of learning, or learning how to learn, rather than on the specific content that is transitory and often outdated by the time it reaches the classroom. In addition to the knowledge goals that are the focus of most university programmes, we bring attention to the skills and attitudes that people have toward the material, and to their potential for visioning into the future. Our primary goal is to nurture the development of autonomous graduates who are prepared to deal with complexity and change, rather than continuing to focus on the curriculum and on what we can prepare and present in the confines of the classroom. As organizers of this learning landscape, we can prepare the next generation of agroecologists to deal effectively with a rapidly changing and undefined future.

In this article we use action learning in its broadest sense: learning through action (McGill and Beaty, 2001). Action learning draws upon the works of Reg Revans (1998), who coined the term, as well as on experiential learning (Dewey, 1916; Kolb, 1984) and critical reflection (Mezirow, 2000). Through action learning, students and teachers learn with and from each other by working together to improve real situations, and by reflecting on their own experiences (McGill and Beaty, 2001).

From Teaching to Learning

One important reason for students to come to the university is to learn something they did not know. There are many dedicated teachers with broad appreciation of what is important, yet some topics may be chosen because they are the research specialties of teachers with narrow research or personal interests. We generally call ourselves teachers, and we really focus on doing teaching very well. Every university has teaching appointments, teaching evaluations and teaching awards. There is an implicit assumption that when we teach, someone will learn. In fact some of us have learned the importance of agroecology and the whole farm and food systems from within the conventional educational structures and integrated this with unique experiences achieved by farmers and others in the world outside academia.

Our Nordic and Midwest agroecology groups strongly believe that we can make more progress through an explicit focus on students and on their learning rather than by fine-tuning classroom methods or the improved organization of a curriculum to fit our time-honoured beliefs in the importance of a certain list of basic and applied courses. This shift is in accordance with the direction of current pedagogical discourses and didactical thinking (Bawden et al, 2000; McGill and Beaty, 2001).

'Just in time education' is a concept that we are exploring for the sequencing of courses in the university curriculum (Salomonsson et al, 2005). Instructors and advisors in the Swedish Agricultural University observed that many students were postponing a required first-year chemistry class until their fourth or even fifth year of study. Careful questioning of students about why they made this decision revealed that many were unsure of how and why they were studying chemistry, except that it was a requirement. Other students were ready for the course in their first year, but many did not understand the context nor had they experienced the need for that information. During their fourth or fifth years, these latter students realized the need for such a course, and it was 'just in time' for them to take it at this stage. When the focus is on learning, we provide opportunities for students to enrol in courses that they find the most purposeful. This does not eliminate the need for thoughtful advising by teachers, who can guide students through the learning landscape to find those courses that will best help them gain the experience and skills that they will need to meet their individual long-term objectives.

Focus on Action Learning

Learning through action and for action is a perspective which is drawn out of Dewey's experience-based learning. According to Dewey, education and upbringing of children is life, and life itself is human growth and development: 'Since growth is the characteristic of life, education is all one with growing; it has no end beyond itself' (Dewey, 1916). His basic idea, learning by doing *and* reflecting, points at our experiences and activities in the world as starting points for learning. Reflective practice, which is so important for professional development, is, however, not an automatic result of experience, since doing does not necessarily lead to learning. It is then the task of the teacher to intentionally facilitate for a situation where learning based on lived experience can take place (van Manen, 1990). It is the task of the teacher to create a genuine situation for experience, which means that the learning of theoretical knowledge has to build on the students' own experience.

The basic principle of action learning is that learning and acting in the world is one and the same thing. As Argyris and Schön (1974, p4) state, 'all human beings, not only professional practitioners, need to become competent in taking action and simultaneously reflect on this action to learn from it'. Learning is thus a process of reflecting on actions in the world, as they appear in one's own experience. In recent years several other pedagogical methods have risen from these basic ideas of Dewey, as experiential learning (Bawden et al, 2000; Kolb, 1984) and problem-based learning (Barrows, 1985, 1986). According to situated learning (Lave and Wenger, 1990), learning as it normally occurs is a function of the activity, context and culture in which it is situated. The theory of situated learning states that in order to achieve a good learning situation, knowledge needs to be present in a socially and culturally authentic context.

In accordance with the findings of Pfeffer (1998), we have observed over many years of dealing with students in the university that there is often a larger gap between knowledge and action than there is between ignorance and knowledge. This is not to endorse ignorance nor to minimize the importance of students expanding their knowledge base, but rather to achieve a compromise that shifts the balance away from total reliance on gaining knowledge to a new balance that puts emphasis on applications. Students may have knowledge and skills, but not an understanding of how to apply the knowledge to real life situations. Most education programmes are designed to add more knowledge and a few specialized skills to what students have already acquired from prior schooling. To be sure, it is important to know how to take soil samples or to recognize weeds in the field, as well as understand how to translate soil analyses or weed counts into recommendations for soil-fertility additives or methods of weed control. But we find that this is not sufficient.

Bringing to attention attitudes toward the environment, and the rural clients with whom we work, is essential in putting knowledge to work. As teachers we obviously display our values, our attitudes and our passions about certain topics to the students, and this is one of the joys of teaching. But this is quite different than only teaching about our own attitudes or forcing a specific point of view. Rather it demonstrates the importance of recognizing attitudes and values as part of education and it is therefore essential for each student to examine their own. This step can bring them closer to action, because they experience that actions made to better the human situation are necessarily grounded in values and attitudes, and that their own actions have a similar grounding.

Another important dimension of education is learning the power of visioning. In the quest for sustainable development, it is not enough to have knowledge and abilities to review the past and analyse the present. In addition, it is vital to have competencies in designing the future. Visionary thinking has a key role in building future-oriented competencies. In accordance with Parker (1990, pp1–2), we see visions as:

> powerful mental images of what we want to create in the future. They reflect what we care about the most, and are harmonious with our values and sense of purpose. Visions are the product of insight, values and imagination, they are the head and the heart working together.

According to Senge (1990), shared vision at its simplest level is the answer to the question, 'What do we want to create?' Visionary thinking, introduced through a three-day seminar for the MSc students, has played a key role in our agroecological education at the Norwegian University for Life Sciences over the past six years. Students value this approach, since developing a coherent view of a potential and desirable future enables them to integrate their diverse case experiences. It also allows them to use the creative sides of their personalities, establishing a bridge from analysing the past and present to start thinking about actions to move from the present to the future desired situation (Lieblein et al, 2001).

Key Characteristics of Agroecological Education

Real life phenomena as the foundation for learning

In contrast to a conventional course where the first lecture describes the history and foundation of that discipline, in the agroecology courses real life phenomena are established as the starting point for the learning process. Rather than agroecological theory having primary value, we immerse students in practical phenomena at the farming and food system levels, and let these phenomena determine what theory is necessary and relevant. We place high value on incorporating students' lived experiences (van Manen, 1990), and reject the mystification of the experiences of everyday life. We think that real life phenomena provide the necessary foundation for inter- and trans-disciplinary activities, because they provide a common language between and among the traditional disciplines. Inductive learning is therefore the preferred basic mode of learning. Agroecology as such is not only a specific body of theory, but it also involves a meaningful way of dealing with complex phenomena in farming and food systems, with the goal to improve those systems. Through such an understanding of agroecology, its two related dimensions become clear: agroecology as a set of theories and as a set of abilities.

Inclusion of divergent modes of learning

We further explicitly introduce the divergent mode of thinking and sharing experience early in the learning process. The process of convergence has been overemphasized as an analytical approach within academia, as opposed to a more innovative, divergent and unstructured mode of thinking and creating meaning. The balance between these two modes of thinking needs to be restored, and the interface between the two needs to be encouraged and expanded. In line with this we critically and creatively need to consider the whole range of possible pedagogical interventions to be able to meet the diverse needs of students, who come with different learning styles and different personal and cultural experiences.

Students as the focus of education

One key principle in our planning and implementing the agroecology courses is that the student is placed in the centre of the activities. In other words, rather than looking at agroecology as a subject matter or discipline, we are concerned about the agroecologist. Thus, the primary goal is not to understand or analyse the agroecosystem, but rather to develop oneself as someone who puts agroecology into practice. More than a discussion about what is the necessary theory to cover is the exploration of what knowledge, skills, attitudes and capacities for visioning we consider important for the agroecologist to have to become an agent of change for sustainable development.

Explicit recognition of student contributions

In line with placing the student in the centre of the programme, we are geared towards learning activities that celebrate and build on contributions from individual students. In this process, 'the inside of the individual is brought out', rather than a one-way information transmission that assumes that the mind of the student is an empty vessel to be filled with theory, 'bringing the outside in'. We see this as an important prerequisite for developing the proactive capacities of students, to enable them to become agents of change. Examples of activities in the courses to build these skills are developing rich pictures of complex situations, mind mapping, dialogue, creative problem solving and visionary thinking. These are all activities driven by students and guided by teachers.

New Roles in Education

Systems- and action-oriented learning implies new roles for all involved in the education of agroecologists. As already stated, the main challenge is to link the subject matter of agroecology, with its interdisciplinary and holistic character, to the students' learning. Our approach, in accordance with action learning and experiential learning, has been to start with the experiences of the students, but not in a fundamentalist sense. As such we see the merging interest in action learning as a reaction to the traditional teaching and theory-based education. This swings the pendulum to the opposite extreme from where the focus is on the theories of the teacher. This has been a necessary shift of focus in education, but the sole application of experiences as a basis for learning has its limitations, and if pursued too far it becomes fundamentalist. The problem is that not all learning is based on our experiences: we also learn from others in a social setting (Bandura, 1977), from the culture in which we are embedded (Lave and Wenger, 1990), but also from theory that may come through a good lecture or a good book. The challenge is to blend many different approaches to meet the needs of many different students. Also, in a strict phenomenological sense, the diversity of real life phenomena needs to be met by a diversity of learning modes. It has been important for us not to go completely from the traditional theory-based teaching to the new practice-based experiences in one large leap, but to widen the field of learning for the students. They should be able to go deep into theory and then deep into practice.

When the focus shifts from teacher to student all parties involved have to find their new roles within the educational system. Lieblein and Østergaard (2001) have called this a 'pedagogy of no mercy', because the feedback becomes especially clear and explicit. The real challenge in a 'pedagogy of no mercy' is that changing from lecturing to improving the students' learning implies losing the control of the learning situation. Through this process the teachers' role changes; the teachers still have the responsibility for the overall learning process, as learning leaders, but also become co-learners together with the students. The students are no longer receivers of knowledge, but have a new role as learners, and their learning involves more than cognition. What the students experience also involves notions, emotions and attitudes. Their learning becomes competency oriented, involving knowledge, skills, attitudes and potential for visioning. Their goals are no longer to uncover answers already known by the teachers or written in textbooks; instead, teachers and students will engage in a joint process to learn about complex real life situations (Francis et al, 2001). The shift from knowledge to competency orientation also implies the shift from a focus on agroecology to the process of becoming an agroecologist. The focus on knowledge is very often connected to the input–output model of knowledge transfer. The competency orientation must on the other hand be related to developing and improving skills through a mutual relation – between the students, between the students and the stakeholders 'out there' and between the students and the teachers.

In this process the roles of theory and practice also change: practice is no longer just used as an example of theories lectured in the classroom, but is used as the starting point for learning. And theory is no longer the focal part of the education, but is seen as something that should support the learners in their development.

Focus on Becoming an Agroecologist

Students embrace a certain field of study because they are motivated, hopefully even passionate, about learning new things and putting them into action. Whatever we do in designing the educational landscape should serve to promote and fulfil that passion, rather than stifling it. An example from classical medical schools is appropriate. The conventional curriculum involved heavy first- and second-year courses in anatomy, learning the Latin names of hundreds of muscles and bones, and this often served as a screening tool to eliminate many who were not capable of, or interested in, such rote learning. Successful memorizers became the specialists who dominate today's medical profession. Some students dropped out because they were bored with material that was important, to be sure, but far from the contacts with real patients that they anticipated. The courses did not fulfill their desire to help people that generated their passion in the first place.

The University of Tromsø in Norway and the Oregon Health Sciences Hospital in the US pioneered the mentoring approach that put medical students into white coats with name badges and stethoscopes right from the first week in school. They took patient histories, made preliminary diagnoses and shadowed mentor doctors for one day each week, thus reinforcing their passion for dealing with people in need. This new and practical approach prevented the unnecessary early screening out of some of the best future doctors with a strong social conscience who may not have been the top academic students based on memorizing bones and muscle names. These potential future caring physicians often despaired of ever seeing patients, and it is likely that we have lost many candidates who could have become the best general practitioners. The new system seems to be working, and it is spreading to other medical schools.

So rather than focus on the time-honoured curriculum, continuing to teach courses in the sequence in which they have always been taught to all students, we should focus on what we want to achieve – a well prepared, knowledgeable, confident graduate in agroecology. We can focus on students and on learning, rather than on teachers and on teaching. We can design learning landscapes and environments that put the joy of discovery into learning, and can put shared responsibility for learning on teachers and students. The schedule and content of classes can include learning skills and new knowledge as well as clarification of attitudes toward the material and potential for visioning the future wanted situation (Schneider et al, 2005).

The strategy described here for planning educational experiences in agroecology is completely focused on who will complete the course of study, how they will put knowledge into action and what they will do when they leave the programme. We call this action education. Students observe and evaluate, and join the faculty in visiting farms, interviewing farmers and families and learning the broad context of the farm situation. The skilled agroecologists graduating from the programme will:

- Have knowledge of farming and food systems.
- Be able to handle complexity and change.
- Be able to link theory to real life situations.
- Be good communicators and facilitators.
- Be autonomous learners.

These competencies are not only vital for dealing with agroecological issues. They are key qualifications (Kämäräinen et al, 2002), which implies that they are transferable; the achieved skills are not limited to an agroecological context, but can be practiced in other parts of life. Agroecology and sustainable agriculture are good places for training these skills. Such skills will be vital to proactively deal with the challenges of specialization, high technology and use of non-renewable resources in modern society in the quest for a sustainable development.

Part IV

Enabling Policies and Institutions for Sustainable Agricultural and Food Systems

16

A New Practice: Facilitating Sustainable Agriculture

Niels G. Röling and M. Annemarie E. Wagemakers

When Greenland Became White

How did our ancestors manage their environment? A green history of the world (Ponting, 1991) and the first conference on how pre-industrial civilizations coped with climate change (Pain, 1994) offer plausible insights.

One case study presented at the conference concerns the medieval Norse settlements in Greenland. Their agriculture prospered during the 12th century. In 1127, they sent a live polar bear to the Nordic King and received a bishop in return. But by 1500, Greenland had become white, and the only people still living there were the Inuit seal hunters. All that remains of the Norse communities are the ruins of their churches.

A comparative analysis of the strategies of the communities of the two peoples for coping with the Small Ice Age reveals that the Norsemen were more concerned with providing for their bishops and building churches than with changing their way of life or agriculture to accommodate the harsher climate. They persisted in trying to graze their cattle on increasingly poor grassland. The Inuit, however, adapted and developed their hunting and fishing in ways that allowed them to survive through the increasing cold.

Though it seems, at first, that the demise of the Greenlanders was caused by climate change, closer scrutiny reveals that the climate was not the only factor.

> By the time the temperature had plummeted in the 1370s, the productivity of the land was falling because of overgrazing and soil erosion. But while the Inuit adopted appropriate technologies of hunting and fishing, the Norse farmers – constrained by their rigidly ordered society and Christian culture – tried to maintain the way of life they were used to. They failed (Pain, 1994).

From this, and other cases presented during the conference, the following conclusions emerge:

- It is not so much climate change that causes problems, but entrenched modes of adapting to change. 'The ability and willingness of society to respond to changing conditions are the crucial conditions in determining whether it survives' (Pain, 1994).
- Such responsiveness depends on individual and collective choices, which are, of necessity, shaped by the past. This makes us vulnerable to discontinuous events for which there are no historical precedents.
- The development and use of knowledge is our main mechanism for survival in conditions of rapid change. That is, adaptation to changing conditions depends on perceiving and interpreting the signs of impending change, and on the timely development of knowledge, technology and organization in reaction to those signs. Thus, the adaptative response also demands creativity and inventiveness and a capacity for collective learning and innovation.
- By virtue of their privileged position, the elites who have a formal or social mandate to provide leadership are often shut off from direct or even indirect experience of the signs of change. They have the power to maintain their lifestyles and the way things are when it is no longer prudent to do so.

Are we like the Norsemen on Greenland?

About this Book

The question could imply that this book is about the Apocalypse, but nothing would be further from the truth. This book is about developing appropriate responses to environmental uncertainty and discontinuity. If anything, its authors are possibly too optimistic in their expectation that it is not beyond human society to make the adaptations that now appear necessary. That does not mean, of course, that we are convinced that meaningful and timely change will come about, but we hope that this book will increase the likelihood that it will.

The more specific aims of the book are to 'capture a new practice'; that is, to examine a number of cases of attempts to make farming more sustainable in conditions of uncertainty. Second, the contributors tease out the lessons of emerging practice with respect to the kinds of learning, facilitation, supporting institutions and conducive policy contexts that are required. The book's central questions therefore are: can we learn our way to a more sustainable agriculture? And if so, what does it take?

The case studies suggest that the answer to the first question is 'Yes'!, but also, that it will take a transformation of our epistemology, our technological and organizational practices, our ways of learning, our institutional frameworks and our policies. Such transformations do not come easy, and the question 'Are we

Norsemen on Greenland?' remains unanswered now that we have finished the book, but we have become a little clearer about the effort that needs to be made and we feel heartened by that understanding.

A Social Science Perspective

This book approaches sustainable farming from the point of view of social science. Hence its central focus is the human actor, and not the biophysical processes occurring in the agroecosystem (see Box 16.1). As you will see later, this has important implications for the way we define sustainability. It also means that this book does not deal in detail with the agronomic or other practices that are needed for using

Box 16.1 *The area of discourse of this book*

1		2		3		4
farm	↔	farmer	↔	facilitator	↔	etc.

The relationship between farmer and farm (1) is that of a human being dealing with biophysical resources and processes. Natural science supports the technologies and interventions used by the farmer to make the biophysical environment yield desired outcomes. These 'technical' aspects do not constitute the area of discourse of this book.

But change in relationship 1 is only possible if the farmer him/herself engages in learning (2). The learning process lies at the heart of this book. As we shall see, the transformation to sustainable agriculture requires a fundamental change in learning processes. These turn out to be very different from the well-established processes of adoption of add-on innovations, in the 'more of the same' fashion, which occur when the farmer tries to improve conventional farm management.

Learning can be facilitated (relationship 3). The facilitation of learning is also a core subject of the book. Most of the contributors, including the editors, are engaged in extension and innovation studies. That is, they are interested in fostering voluntary change in behaviour through communication, and in innovation as an outcome of social interaction (e.g. Röling, 1988). Other perspectives on innovation, for example, as a process induced by changes in relative factor prices (Ruttan and Hayami, 1984) are not dealt with, although we recognize that changed relative factor prices might well motivate innovative interaction.

The case studies reaffirm the proposition that learning and facilitation occur in specific institutional frameworks and policy contexts (relationship 4), and that the nature of these frameworks and contexts is of crucial importance for the transformation of farming. Moreover, the cases illustrate how the institutional and policy changes required for scaling-up successes achieved on a pilot scale cause strife and conflict for which appropriate communication and negotiation strategies and methodologies are needed.

natural resources in a more sustainable manner. A great deal of information is available on that issue (e.g. Howard, 1943; National Science Council, 1989; Reijntjes et al, 1992; Pretty, 1995). Jiggins and De Zeeuw (1992) provide pioneering information on Participatory Technology Development (PTD) for sustainable farming, while Pretty's (1995) authoritative book on regenerating agriculture provides a wealth of information on its feasibility and the conditions for transformation.

We do not limit ourselves to the field or farm level, but explicitly also take into consideration larger-scale agroecosystems, such as water catchments, which need to be managed in their own right in order to allow sustainable management at the field and farm levels. Since this book assumes that the transformation to sustainable farming is social as much as agronomic and ecological (Vartdall, 1995), we shall examine these agroecosystems by looking at innovation processes at levels of social aggregation concomitant with the scale of the agroecosystem.

The contributors to the book bring along a wide range of experience assembled during widely different life times, from widely different contexts, which allows examination of the transition to sustainable agriculture from widely different perspectives, at different levels and along different dimensions (Box 16.2).

Box 16.2 *Profile of the contributors*

Campbell and Wagemans are senior policy makers in government, while Woodhill plays the same role in an environmental voluntary organization. All three also undertake consultancies in other parts of the world.

Fisk, Hesterman and Thorburn work for the W.K. Kellogg Foundation (WKKF) in various capacities. WKKF is a philanthropic foundation which supports learning in and about agriculture and rural development.

Boerma, Hamilton, Roux, Van de Fliert and Van Weperen play professional roles as consultants, project leaders or implementors.

Aarts, Gerber, Koutsouris, Papadopoulos, Proost, Van de Fliert (who has two jobs) and Wagemakers work for universities as lecturers and researchers; Somers is a researcher in a research institute.

Blum, Castillo, Hoffmann, Pretty, Röling and Van Woerkum are university professors who hold (or held, Castillo is emeritus professor) chairs in departments of extension studies of one kind or another. Jiggins holds a chair in the field of human ecology. Hesterman has worked as a professor in crop and soil science. All undertake consultancies in various parts of the world.

Sustainable Agriculture

Productivity equity, sustainability and stability have been identified as key goals of agricultural policy (Conway, 1994). But they are not necessarily mutually consistent. Conway speaks of 'trade-offs' among them, especially between the economic and ecological. This book is weighted heavily towards ecological imperatives. Maintaining or enhancing the natural resource base is the precondition for a sustainably productive agriculture.

Box 16.3 outlines the main aspects we shall examine. These aspects relate systemically to one another, in that change in one aspect necessarily affects the others. For example, the learning required for effectively practising Integrated Pest Management can apparently not be achieved by the transfer-of-technology (TOT) mode of extension. It requires a new approach to facilitation (Matteson et al, 1992), which in turn has important implications for institutional support. We come back to the five dimensions in the last chapter, where we examine models of innovation which are suitable for understanding the transformation to sustainable farming.

We shall not define sustainability solely in terms of the carrying capacity or other 'hard' characteristics of an agroecosystem. We use a social science definition (Box 16.4) that, as our cases show, proves to be eminently practical. We borrowed the definition from the 'Hawkesbury pioneers', a small band of agriculturalists at the University of Western Sydney in New South Wales (Sriskandarajah et al, 1989; Bawden and Packam, 1991; Woodhill, 1993; Ison, 1994).

The definition in Box 16.4 incorporates elements which focus on the hard properties of a farm or an agroecosystem. Yet we suspect that our seemingly relativist definition will irritate those who want to use scientific definitions to identify the limits beyond which use of natural resources should not go (Korthals, 1994).

Box 16.3 *Five interlocking dimensions of the transformation to sustainable farming*

- agricultural practices, both at the farm and higher system levels;
- learning those practices;
- facilitating that learning;
- institutional frameworks that support such facilitation, comprising markets, science, extension, networks of innovation etc.;
- conducive policy frameworks, including regulations, subsidies etc.; and especially:
- the management of change from conventional to sustainable agriculture along each of the dimensions.

Box 16.4 *Sustainability defined*

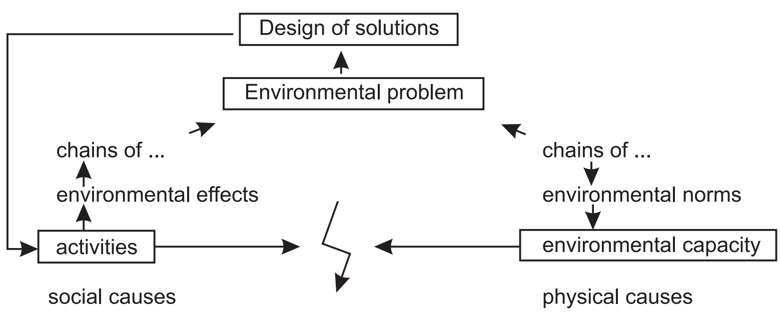
Sustainability is an emergent property of a 'soft system' (Woodhill and Röling, this volume). It is the outcome of the collective decision making that arises from interaction among stakeholders. Stakeholders are identified here as natural resource users and managers. A natural resource can be considered at the field, farm or higher level of aggregation, including watersheds, landscapes, agroecological regions, lakes and rivers and, ultimately, the Earth itself.

The formulation of sustainability in this manner implies that the definition is part of the problem that stakeholders have to resolve (Pretty, 1995). That is, securing agreement on what people shall take sustainability to mean for a given environment, is half the job of getting there.

None the less, our definition, as this book shows, has proven robust because it fits so well the outcomes of research on the interface between people and their environment. It also serves our immediate purpose of illuminating the facilitation of sustainable agriculture.

Our definition is consistent with Wouter de Groot's (1992) 'problem-in-context framework for the analysis, explanation and solution of environmental problems' (Box 16.5). A problem is here defined as an undesirable difference between 'wants' or norms, and 'gets' or impacts. According to De Groot, an environmental problem is an undesirable difference between the environmental impacts of human activity and environmental norms. Solving environmental problems thus requires changing human activity to fit the norms, and vice versa. The problem-in-context framework provides for an integration of environmental sciences and the derivation of norms for human activity.

Box 16.5 *De Groot's 'Problem in Contex Model' of environmental problems (simplified adaptation of De Groot, 1992).*



Is it Immoral to be Concerned About the Health of Natural Resources?

The term 'sustainable agriculture' implies regenerative practices which optimally use locally available resources and natural processes, such as nutrient recycling; build on biodiversity; regenerate and develop natural resources; and limit the use of external inputs of agrochemicals, minerals and non-renewable energy. Regenerative agriculture requires that, where used, such external inputs are used efficiently so that emissions can be recycled and absorbed (Pretty, 1995), renewable resources are regeared and non-renewable resource use generates optimal productivity.

Defined in this way, regenerative agriculture, in terms of yield, at present tends to be slightly less productive than high-input agriculture in industrial countries, and approximately as productive as such agriculture in 'Green Revolution' areas. On presently available evidence, state-of-the-art regenerative practices would increase significantly productivity in the rainfed, complex and resource poor areas in developing countries which have so far not benefitted from high external input technologies and are usually heavily degraded (Pretty, 1995).

The question then arises whether, from a global point of view, regenerative agriculture can deliver the output required to meet aggregate demands. The trend line extrapolation of growth in the world's population to more than 8 billion in 2025, an increase of over 2.5 billion in the next 30 years, has led many authors to emphasize the need to double productivity per hectare of available farm land (McCalla, 1994; CGIAR, 1995; Tansey and Worsely, 1995).

The productivity deemed possible under regenerative agriculture and the doubling of productivity per hectare of available land required by 2025 seem contradictory. Indeed, one expert claims that promoting a form of agriculture which uses no artificial fertilizers or chemical pesticides is immoral because it undermines global food security (quoted from Rabbinge in WUB 17, 11 May 1995).

It suffices in this introductory chapter to highlight the irreducible uncertainty about what lies ahead over the next two or three decades. On the one hand, while there is at present ample grain available in global food markets to feed the world's present population, many millions continue to go to bed hungry. This has to do with the fact that surplus production is not directly related to the relief of chronic hunger. Many of those who are hungry have neither the means to produce sufficient to feed themselves, nor the money to buy it. The issues of inequity and distribution are likely to remain present into the foreseeable future, at any level of grain production, or population growth or environmental change.

On the other hand, although present estimates of production potential indicate adequate capacity to meet the food needs in aggregate of up to twice as many people as are alive today, such estimates are by their very nature conditional, and hedged around by assumptions about what might happen in other sectors. For example, estimates of the future adequacy of water supplies to agriculture are dependent on considerations such as demands for water from industrial, recreational and domestic users, the rate at which water loss is controlled, the efficiency of water use and the rate at which water-winning and water storage technology is introduced.

Further food output scenarios also are strongly affected by assumptions made about the outcome of political negotiations concerning acceptable levels of environmental pollution, degradation and waste, questimates concerning the mobilization of political will to invest in the health of soil amelioration measures, which would open up hitherto unusable areas to cultivation, as well as price relationships, market developments and changes in consumer preferences.

In addition, the introduction of factory-based production of meat muscle (already foreshadowed in the UK Government's technology foresight programme) could relieve much of the pressure of livestock farming on grasslands, for example, while an acceleration of the already observable shift towards more vegetarian diets in Northern consumer markets (e.g. Kleiner, 1996) would markedly change food demand forecasts. The likelihood of rapid change in global temperature and rainfall patterns adds further uncertainty.

Conversely, continued reliance on high-energy input, chemical-dependent, intensive farming as the sole or even the main source of global surplus would appear to be environmentally foolhardy, and increasingly unacceptable politically as the wider consequences to human health, ecosystem and valued landscapes become apparent.

'Making the Flip'

Historically, the number of people and their 'wants' have grown, and uses of natural resources to satisfy them have been developed, regardless of the longer-term consequences for the environment (Ponting, 1991). In this book, we consider the alternative, indeed the necessity, of 'making the flip':

- conserving, even enhancing, the natural resource base upon which all agriculture ultimately, and indeed human survival, depends;
- the resultant negotiations involved in the transformation of wants to accommodate the emergent understanding of the natural resource imperative;
- the kinds of agriculture which then results from such a reversal of attitudes, approaches and behaviour.

The book illustrates the social energy which is created as people and institutions begin to engage in accommodation of 'wants' to 'effects'. The evidence suggests explicitly that the way to capture the potential for productivity, which is realizable by paying heed to the health of natural resources, is to work with and support the creativity, diversity and serendipity which emerges from a process of social learning.

In agriculture, the process requires that farmers become experts, instead of 'users', 'receivers' or 'adopters' of other specialists' wisdom and technologies. They must learn to apply general ecological principles to their own locality and time-specific situations. They must be able to manage complex agroecosystem systems as businesses in competitive markets. But, as ecosystems do not stop at farm boundaries, local communities and wider consortia of interest groups and resource users also need to engage in learning how to manage landscapes and resources. Societies have to develop, and adjust to, trade-offs among potentially competing interests. We still have a long way to go in that respect. On the whole, a wasteful way of life has so far remained politically non-negotiable.

The Prevalent Paradigm for Thinking About Innovation

The current ways of thinking about the processes of innovation are embedded in a particular *epistemology*, that is in ways or methods for knowing on the basis of knowledge which hitherto has remained largely unchallenged.

The prevalent view of agricultural science is that it deals with 'things', which are as they are, which can be objectively known through research, and about which science can formulate generalizable 'truths'. These objectively verifiable propositions underpin the efforts made to influence agricultural performance. The goals of such intervention are taken to be unambiguous and not of scientific interest. The focus is on the 'best technical means' for achieving any stated goal. Box 16.6 presents typical statements which are informed by this so-called realist–positivist epistemology.

Box 16.6 *Illustrative realist–positivist statements*

- Reality exists independently of the human observer.
- Through scientific research we can build objective, true knowledge (generalizations) about that reality.
- Scientists discover and lay bare the naked truth, lift the veil hiding it, and reveal its secrets.
- The goal of science is to add to the store of human knowledge.
- Scientific research is the source of innovation.
- Technology is applied science.
- Development results from the transfer of the results of science to users.
- Problems can be solved by experts. In fact, we do not have to worry too much about the future. Science will find an answer.
- Social science is not really a science: it has not resulted in any true generalizations and cannot be used to send a man to the moon.

The realist–positivist epistemology is a coherent and internally consistent paradigm which most agricultural professionals have drilled into them, or absorb during their training, whether it is technical or social, and whether it is at an academic, polytechnic or secondary level institute. But it is an epistemology which is increasingly incompatible with the search for a sustainable society.

Kuhn (1970) has opened our eyes to the notion of coherent and internally consistent paradigms which shift as the number of plausible knowledge claims which are in conflict with them increases. We then move from a period of 'normal science' during which people agree on the fundamental premises and occupy themselves with questions within the paradigm, into a period of 'post-normal' science, during which the paradigm itself is contested.

An increasing number of knowledge claims which are inconsistent with the realist–positivist paradigm (Box 16.7) arise in current debates about agriculture and the environment.

Box 16.7 *Some claims at odds with the realist–positivist paradigm*

- Agriculture has multiple goals which are not mutually compatible. Hence the assumption of unambiguous goals and the focus on 'best technical means' is becoming irrelevant. The need for arbitration among contested goals is becoming one of the key challenges in dealing with our natural resources.

- Decisions about the use of natural resources are less and less a question of expertise or the province of specialist institutions, and more and more determined by negotiation and agreement among stakeholders. The focus shifts from result to process. The problems we are faced with have less to do with instrumental problems, i.e. people–thing problems, and increasingly to do with people–people relationships, i.e. social problems. This has important implications for agricultural science which has so far profiled itself as a biophysical and technical activity.

- In the conventional paradigm, innovation is seen to originate in science and to be realized through the transfer and adoption of the results of science (the linear model or transfer-of-technology (TOT) model). But it is increasingly clear that, in practice, innovation emerges from interaction among various 'actors', i.e. among people and collectivities as role playing and sense making beings. Each one contributes to the final outcome (e.g. Kline and Rosenberg, 1986; Engel, 1995). Local knowledge, business ingenuity, farmer experimentation and inventiveness are as important as expert knowledge and the role of specialized actors such as scientists and farm advisors.

- Agricultural development is conventionally seen as driven by technological change. However, few would now disagree that price changes, improved institutional support (reducing transaction costs), conducive policy contexts, value shifts and social organization can be necessary conditions for, and sometimes the stimulus of, innovation.

The erosion of realist–positivism as a universally trusted epistemology appears to be associated with other important societal changes. For one, the trust in experts and specialized institutions is waning. A recent survey found, for example, that British respondents do not trust the information about biotechnology which they get from scientists, business corporations or the Department of Trade and Industry. They prefer to trust organizations such as Greenpeace (Tate, 1995).

The erosion of trust also appears to be related to uncertainty about issues for which the stakes are high, such as global food security which was touched upon in the section 'Is it Immoral to be Concerned About the Health of Natural Resources?' and 'Making the Flip'. Funtowicz and Ravetz (1990, 1994) argue that we have entered a period of 'post-normal science' in the sense of Kuhn (1970) because 'normal science' cannot deal with conditions of high uncertainty. The development of reliable grounds for knowing must proceed in part along other lines. Self-appointed activists emerge, who become formidably well informed across discipline boundaries about a subject or situation which threatens their values or livelihood. Decision fora include speech-makers and citizens, as well as scientists or specialists, and 'facts' encompass people's values and express cultural meaning. The final arbiters of reliable knowledge are 'extended peer communities' made up of a much wider membership than the conventional narrow professional elites or restricted political circles.

Funtowicz and Ravetz (1994) speak of the 'democratization of science'; that is, a widely shared process of learning and informed public debate about goals, and not just means, seems the only acceptable way to deal with high uncertainty when the stakes are high and the consequences of getting it wrong are potentially catastrophic.

This observation is reminiscent of Habermas' (1984, 1985) argument that society can overcome the momentum of what we have constructed in the past – and thus prevent the Norsemen on Greenland scenario – only by reaching consensus about what action to take next; that is, not on the basis of controlling things (instrumental rationality), nor on the basis of beating competitors or opponents (strategic rationality), but on the basis of shared learning, collaboration and the development of consensus about the action to take (communicative rationality).

Constructionism

Constructionism is the name given to the epistemology which supports the learning processes described in this book. If everyone agrees about the goals, we can afford to worry about the best technical means of securing those goals. If everyone agrees about the facts, we can speak of objective truth. 'Objective' knowledge has, therefore, by no means become outdated or unneeded. But, if these conditions do not hold, we have to stretch the positivist epistemology and embrace constructionism. Reality no longer appears as a 'given' but as something actively 'constructed'

Box 16.8 *Constructionism and quantum physics*

Niels Bohr did not believe in the Newtonian clockwork universe (which was the conventional perspective early this century). 'There is no quantum world. What exists is a quantum physical description. It would be mistaken, therefore, to believe that it is the task of physics to find out what nature is. Physics occupies itself with what we can say about nature' (quoted in NRC/Handelsblad, 18 May 1995). Another quantum physicist, David Bohm, said: 'It is not the task of science to increase the store of knowledge, but to formulate fresh perspectives' (1993). Some researchers and analysts reject constructionism because of its apparent relativism (Röling, 1995). If it is people who construct reality, there must be multiple realities. What the one has constructed can be deconstructed by someone else. Everything can be true.

by people. There are three main strands in constructionist thinking (Knorr-Cetina, 1995).

In the first place, reality is said to be socially constructed (Berger and Luckmann, 1967). It is created in the discourse of, and negotiations among, people as social actors. Socially negotiated agreements become experienced as 'objective' truth. Berger and Luckmann concern themselves with the mechanisms by which objective social order emerges from interaction.

Second, convincing empirical analysis of 'fact production' in natural science laboratories by, e.g. Knorr-Cetina herself (1981); Collins (1985, 1992) and Latour (1987) has focused attention on epistemic practices and human construction in the very area we used to think of as given natural reality (Box 16.8).

Third, biological research into the 'observing organism' (Maturana and Varela, 1987) has demonstrated that the environment external to the observer, be it a frog or a person, does not project itself objectively on to the nervous system. Perception is accomplished by the brain, and the brain is an informationally closed system that reconstructs an external environment only from environmental 'triggers', memory and interaction with itself.

We explicitly reject such an interpretation of constructionism. There is an environment. If an organism loses touch with it, or, as Maturana and Varela (1987) put it, if the structural coupling between organism and environment is broken, the organism cannot survive. But the 'constructions' appropriate for survival are not fixed or self-evident, nor is their interpretation unambiguous. They have selectively evolved, are culturally conditioned, continue to be actively created, or learned experientially on the basis of trial and error, or vicariously on the basis of communication. In this scheme of things, science has a role to play. It is engaged in the active construction of reality. But its impact is not based on the predictive power of its generalizations, however, but on the extent to which it affects other people's reality construction.

Social actor network theory (Latour, 1987; Callon and Law, 1989) takes this a bit further. It claims that the impact of scientific results is based on the extent to which the laboratory conditions, which gave rise to the results, are replicated in society. These conditions are the outcome of the efforts of people who have an interest in creating and maintaining them. That is, 'social actor networks' are necessary to maintain these conditions. Changing the conditions, for example, as a result of trying to reduce the use of chemical inputs in agriculture, invariably leads to resistance as actors' interests are affected (e.g. Aarts and Van Woerkum; Hamilton). The transformation to sustainable agriculture is not politically neutral.

What about the impact of social science? As we have seen earlier, from a positivist point of view, social science has little to contribute, but from a constructionist view, the contributions are assessed in different terms. All forms of knowledge which claim the 'science label', social science included, are seen as special cases of social reality construction. The scientist actively constructs a fresh perspective on reality and this, in turn, affects the way others see it. Giddens (1987) has called this 'the double hermeneutic'. The behaviour of celestial bodies such as the sun and the Earth presumably remain the same, whether people think the sun circles around the Earth or vice versa, but people and societies do change their behaviour in the light of what science has to say about celestial movements. This also holds for the social sciences. Economics, for example, has been quite effective during the past few decades in making us believe that we are largely driven by maximization of monetary values and that society must be organized to allow the unhindered operation of market mechanisms.

The impact of constructionist thinking becomes abundantly clear if we consider what it implies for the professional field of most of the contributors to this book: extension studies (Box 16.9) (Leeuwis, 1993). Within the realist–positivist epistemology, extension is looked upon as a necessary delivery mechanism of the results of scientific research. We do not need to repeat the criticism of that perspective here (Freire, 1972; Chambers, 1983; Kline and Rosenberg, 1986; Röling, 1988; Long and Van der Ploeg, 1989). Within the constructionist epistemology, extension is a means for socially (re-)constructing agrarian reality through communication and information sharing activities. More generously and truly constructionally, extension can be seen as a societal mechanism for facilitating social learning of appropriate responses to changing circumstance. It is easy to see from this perspective how the transformation of agriculture implies an active social reconstruction of what our natural resources mean to our survival, and how to use them to support our continuing livelihood. It is equally easy to see that the transformation cannot be accomplished only on the basis of positivist science, elite expertise and on transfer of technology to farmers.

Soft Systems Thinking

Finally, it is necessary to say by way of introduction that we accept systems thinking as a necessary holistic approach to complex issues such as the sustainability of agroecosystems. Such issues cannot be understood by examining only the parts in

Box 16.9 *Extension*

Although literally hundreds of thousands of people in the world earn their living as professional extensionists, the area of endeavour remains murky and difficult to explain. One reason is the diversity of perspectives with which extension is construed and which are often based on differences in basic assumptions about agricultural development, the role of science and so forth.

The word 'extension' originally refers to extending scientific education beyond the walls of school or university (Van den Ban and Hawkins, 1988, 1996). Often the word 'extension education' has therefore been used. This idea is close to the French concept of 'vulgarization', making accessible scientific or other elevated thoughts to the 'vulgus' or ordinary people. Consistent with this notion is the emphasis on technology transfer from scientific research to farmer users (the TOT model) as the central mandate of extension.

But, other concepts are being used which reflect an entirely different perspective. Thus farm advisory workers, or, in German, 'Beraters', have less of an educational or transfer and more of a consultant role. Words such as 'mobilizer' or 'facilitator', which try to avoid the implication of external imposition, go even further.

Extension, as a practice, is underpinned by a body of knowledge and accumulated experience which has, at one time, been called 'extension science' (Röling, 1988), but which perhaps can be better labelled as 'extension communication and innovation studies' to reflect a more constructionist perspective on science. Many of the contributors to this book are engaged in such studies (Box 16.2).

But, extension and innovation studies cannot be considered a discipline. Innovation, including the transition to sustainable agriculture, cannot be understood by focusing only on extension communication, but requires taking account of intentionality, culture, power, technology development, institutions, policies and, of course, epistemology.

isolation, nor the whole as a mere aggregation of parts. Tasks such as ecosystem management require that the emergent properties of systems as wholes are taken into account (e.g. Hurthubise, 1984). 'System performance must therefore be judged not simply in terms of how each part works separately, but in terms of how the parts fit together and relate to each other, and in terms of how the system relates to its environment and to other systems in that environment' (Dillon, 1976).

Constructionism has deeply affected the thinking about systems which emerged from biology and other 'hard' sciences and was later applied in engineering. Checkland (1981; Checkland and Scholes, 1990) distinguishes between 'hard' and 'soft' systems. The former are treated as if they really exist. Their boundaries and goals are assumed to be given. Analysis and problem solving focus on goal-seeking and the best technical means to reach a goal. Such hard system thinking can be usefully applied to natural systems, such as plants, or designed systems, such as computers.

Soft systems are deliberate social constructs, that is, they exist only to the extent that people agree on their goals, their boundaries, their membership and their usefulness. The crucial assumption is that system goals are not given but contested and that system boundaries are negotiated. The necessary condition for a soft system to exist is agreement among its members on its goals. A soft system may also be defined as a human activity system, e.g. an organization, a task force or the stakeholders in an agroecosystem who have been forced by environmental problems to exert joint agency at the level of social aggregation commensurate with the agroecosystem. Thus the agroecosystem is a subsystem of a human activity system, and its sustainability is an emergent property of that soft system. In this perspective, hard systems are subsumed by soft systems, just as scientific research is a special approach to the social construction of reality.

A special application of soft systems thinking is represented in what are called agricultural knowledge and information systems (AKIS) (Röling, 1988, Röling, 1990; Röling and Engel, 1991; Engel, 1995). AKIS can be used in a number of ways:

- empirically to discover how social actors in agriculture, such as scientists, advisers, farmers, but also seed suppliers, credit banks and so on, are linked together in the creation, adaptation, sharing, storage and application of knowledge and information;
- normatively, as a mental construct, to design ideal links and flows;
- analytically to guide interventions to ensure that the actors do, in practice, interact in ways that give rise to desired emergent properties, such as innovation. System boundaries can be drawn widely, to achieve goals such as a competitive and productive and/or indeed a sustainable agriculture, or narrowly to achieve goals such as the production of *x*-litres of milk per cow.

Peter Checkland's real achievement is the development of a soft systems methodology (SSM), which allows a group of actors who are faced with a shared problem to engage in a collective learning process in order to design a human activity system that can help solve the problem through collective action. SSM has been tested extensively over a period of more than 15 years, but especially in corporate environments. At a workshop with Checkland and some of the present contributors, it was noted that sustainability problems are more complex than corporate ones with respect to the social dilemmas which arise between individual and collective interests (Ostrom, 1990, 1991, 1992; Koelen and Röling, 1994; Maarleveld, 1996) and hence require more preliminary exploration (Leeuwis, 1993).

Subsidies in Watershed Development Projects in India: Distortions and Opportunities

John M. Kerr, N. K. Sanghi and G. Sriramappa

> Development is increasingly understood to be a process whereby people learn to take charge of their own lives and solve their own problems. Helping people solve their problems by giving them things and doing things for them makes them more dependent and less willing to solve their own problems. This cannot be called development; on the contrary, it is the very opposite of development (Bunch, 1982).

Heavy subsidies are a standard component of virtually all agricultural and rural development projects in India. It is difficult to find examples of government or non-governmental projects that do not include substantial funding from the sponsoring agency. Such funding can take several forms: helping to pay for labour, agricultural inputs, machinery services or technical expertise. Sometimes assistance is provided to help rural people carry out work on their own, and sometimes the work is done for them.

This chapter discusses the effects of subsidies on watershed development projects, particularly in India, although the arguments presented are relevant throughout the world. In this chapter we do not argue against government support for agriculture and poverty alleviation. Rather, we aim to show that some unintended, negative consequences of heavy subsidies in watershed management programmes actually undermine watershed development objectives. The cause of the problem is that often watershed subsidies are intended simultaneously to support improved land management and rural employment generation. This is a lot to demand of a single policy intervention. We argue that watershed programmes could be more successful if these subsidies were reduced or eliminated, and the objectives of support for agriculture and poverty alleviation were achieved through alternative means. We conclude by suggesting alternative approaches that avoid subsidies or minimize their potentially destructive impacts.

Reprinted from Kerr J M, Sanghi N K and Sriramappa G. 1999. Subsidies in watershed development projects in India: Distortions and opportunities. In Hinchcliffe F et al (eds) *Fertile Ground.* IT Publications, London. Chapter 14, pp178–193.

Government Support for Agriculture and Human Welfare

Subsidies and payments to rural people have a long history in India. Employment generation for famine relief, for example, dates back several centuries. In contemporary times, many state governments sponsor employment programmes that provide important welfare benefits. Whether for constructing irrigation canals or promoting watershed development, employment generation can easily be built into a range of rural development projects and produce tangible benefits, such as combating hunger and stabilizing rural income.

Subsidies are also often seen as a useful way to convince farmers to try something that subsequently they will adopt with their own resources. This faith in the 'demonstration effect' is common among agricultural researchers worldwide, who believe that the technologies they develop will be adopted if farmers are shown their merits. The success of the Green Revolution contributed to this sentiment in India. In the Green Revolution, scientists' discoveries on agricultural research stations led farmers literally to replace traditional farming systems, resulting in spectacular productivity increases.

Agricultural demonstrations in India take several forms. Those conducted on farmers' fields normally involve subsidies. Researchers often select a farmer who receives free inputs if he donates a field to be used as a demonstration plot. Researchers then select a technical model to test on the plot. On a larger scale, watershed programmes often supply farmers with partially or fully subsidized inputs in exchange for allowing watershed works to be implemented in their fields, or to demonstrate to farmers the complementary effects of improved inputs and cultivation practices.

Some soil and water conservation (SWC) projects in India operate in areas where agriculture imposes external costs, or externalities, in downstream locations. The classic case is when erosion on farm land leads to siltation of reservoirs or other downstream infrastructure, decreasing their lifespan at a high cost to the national economy. Several publications of the Central Soil and Water Conservation Research and Training Institute in Dehra Dun display a photograph of a bridge in the Dun Valley that was nearly engulfed by half a century of upstream erosion (CSWCRTI, 1989). Images such as this leave a powerful impression of the need for government to help pay for erosion control measures on farms, even though such externalities are not present in every case.

Subsidies were also built into early SWC programmes because of official perceptions that farmers were ignorant and would manage their land properly only under coercion or persuasion. In some cases officials designed programmes that forced farmers to comply. But farmers resisted compulsory programmes; often destroying measures introduced against their wishes after the soil conservation officials leave (Fernandez, 1993).

Today, many people view compulsory programmes as unacceptably authoritarian in nature. They seek another way to encourage farmers to adopt soil conservation practices. Paying farmers for work done on their fields offers a more socially acceptable way to try to achieve conservation objectives.

In recent years subsidies have assumed great political importance. This is partly because India, unlike many other developing countries, is a functioning democracy. The rural vote is always hotly contested in Indian elections, with politicians often resorting to vote-buying schemes such as loan forgiveness and a wide range of subsidies to attract the rural constituency.[1]

The combined result of these efforts to create employment, demonstrate technology, combat externalities, guide 'ignorant' farmers and gain political influence, is that most people in India do not question subsidies for agricultural development projects. Farmers have learned from experience that they may always expect subsidies, and the rest of society accepts – apparently without question – the idea that it should share the cost of measures intended to help farmers. There is little debate about why these subsidies are justified or what objectives they achieve. Here we argue that subsidies can hinder attempts to increase agricultural productivity and conserve natural resources.

When are Subsidies Appropriate and When are they not?

Economic policies should be used to accomplish objectives that the free market does not achieve on its own. For example, they are needed when the market sends signals to people to produce, consume or invest in ways that are economically optimal for the individual but not economically optimal for society as a whole. In the language of economics, under these circumstances the private costs and returns of an activity do not equal the social costs and returns. This situation is referred to as a market failure (Box 17.1). A policy intervention such as a tax, subsidy or a change in the laws that govern the market, can correct the market failure by realigning private and social returns of the economic activity in question. Direct government intervention can also be used to provide goods and services that the market does not provide.

Policy makers have many possible economic tools for correcting market failures. These include granting subsidies, levying taxes, assigning and specifying property rights, improving credit and insurance markets and many others. The important point is that subsidies are just one of many policy tools. Depending on the market failure at hand, a subsidy may or may not be the most appropriate policy tool.

In economic terms, introducing a subsidy is justified if two broad conditions apply:

- There must be a market failure (see Box 17.1).
- A subsidy must be the best way to correct the market failure, i.e. the one that solves the problem as directly and inexpensively as possible, with minimal side effects.

Box 17.1 *Types of market failure*

Examples of market failure, when market prices signal people to carry out activities that are not in society's economic interests, abound in natural resource management and have a variety of causes.

Gadgil (1992) describes how forest product firms with short-term concessionary rights to forest land over-harvested forests because they had no stake in their future productivity. Similarly, farmers collectively over-exploit groundwater in semi-arid regions because there are no property rights governing access to groundwater, and because electricity price subsidies encourage overuse (Kerr et al, 1997).

Village irrigation tanks are poorly managed because traditional institutions for collective action have deteriorated. Pender (1993) found that many poor farmers wished to invest in wells but could not do so due to credit constraints. Farmers in dryland conditions apply less than optimal amounts of fertilizer because of the risk that their investment will be wasted if rainfall is insufficient. In all of these cases of market failure – externalities, short time horizons, unspecified property rights, credit constraints, risk, and others – the market fails to encourage the best pattern of natural resource management, and some policy intervention is needed to make the market work better.

A policy tool that is not directly targeted to the cause of a problem might fail to solve it, or even worsen it (Box 17.2).

A subsidy should address the causes of problems, not their symptoms. A subsidy is an appropriate tool, for example, if the problem is that farmers do not invest in watershed development because the benefits go to the national economy but not to the investing farmer. In this case a subsidy can raise private returns to match social returns. On the other hand, if the problem is that a farmer cannot invest in planting trees or digging a well because he lacks access to credit, the policy should be to provide credit. A subsidy might encourage the investment in trees or wells, but it is wasteful because a less expensive policy could have achieved the same objective.

Box 17.2 *The consequences of poorly targeted policy*

In India and several other countries, policy makers alarmed by the loss of tree cover introduced laws against cutting and marketing trees, on both public and private land. On private land this legislation had a serious side effect: farmers planted fewer trees because they feared that they would not be able to sell them (Chambers et al, 1989a; Murray, 1994). The policy that was chosen was not direct enough in addressing the problem of deforestation on public land. It also had the side effect of discouraging farmers from increasing tree cover on private land. A better policy would have helped farmers plant trees and market tree products while controlling the problem of logging in public forests.

In other words, in some cases subsidies are the best policy tool, but in other cases they are not. And they have four major drawbacks:

1 They cannot be extended to everyone, because funds are limited.
2 They are wasteful in cases where another policy could be used to accomplish the desired objectives.
3 They may be difficult to remove once put in place.
4 They may cause unwanted side effects.

How Subsidies Affect Incentives

As stated above, a subsidy is a payment or service that raises the net private returns from an activity; an incentive is something that motivates or stimulates a person to act.[2] Financial subsidies are intended to increase financial incentives, but other types of incentives can be social, moral, psychological or political. There are different types of subsidies and these have different effects on a range of incentives or motivations.

Financial subsidies

Most people think of finance when they think of subsidies. The intention of a financial subsidy is to raise the incentive for people to pursue the subsidized activity. Subsidizing production of oilseeds encourages farmers to plant more of them, and subsidizing construction of contour bunds encourages farmers to build them. The economics of subsidies appears to be very simple: by making the subsidized item less expensive or more remunerative, more people will be willing to pay for more of it.

Paradoxically, financial subsidies can reduce financial incentives for people to invest their resources in subsidized activities. If a soil conservation programme subsidizes construction of conservation ditches in one village, for example, then farmers in a neighbouring village who are considering investing in conservation ditches have an incentive to postpone the investment in the hope that the programme will soon operate in their village as well. The farmer whose conservation ditch was subsidized this year has an incentive to postpone repairing or rebuilding it in the hope that a future conservation programme will pay for it. Numerous SWC programmes throughout the world have faced this experience.

Subsidies also discriminate against products and practices that are not subsidized. If a subsidy reduces the cost of a commodity or technology or a certain way of doing things, it creates a disincentive to use substitute products or technologies. Electricity subsidies, for example, can reduce the incentive to search for alternatives such as solar-powered pumps. Over time, this can impede scientific progress and stifle indigenous knowledge because it reduces payoffs for innovating and finding less expensive, more efficient ways to do things. In the case of watershed management, subsidies for certain conservation techniques reduce incentives to try other, less expensive ones.

Financial subsidies also create opportunities for corruption because they put officials and influential beneficiaries in a position to mismanage funds and other programme benefits. In a worldwide review of food-for-work programmes, corruption occurred more often than not (Jackson, 1982).

Psychological and moral disincentives

Financial subsidies risk causing even more damage to psychological, social or moral incentives than to financial incentives. The experiences of innumerable agricultural development projects around the world demonstrate the psychological effects of cash and kind subsidies. Too often, villagers who receive free machines, irrigation wells or other items do not maintain or manage them properly. They value the services of free items, but they do not treat them as they would treat something they paid for themselves. These free items, or giveaways, never seem to last as long as comparable items purchased by farmers with their own money. If the machine breaks, they look to the agency that provided it to repair or replace it.

Rural development agencies everywhere are now finding it difficult to operate without subsidies because villagers accustomed to giveaways act as though they are morally entitled to handouts, but not morally responsible for trying to solve their own problems. In this sense financial subsidies create *disincentives* that retard development.

Subsidized services

Development projects that provide services rather than funds offer another form of subsidy. Some subsidized services play an important role in the economic development and well-being of any country, and their potential benefits should not be discounted. Education is the best example. In rural development efforts, assistance that enables people to do things they could not (or believe they could not) do, can have a powerful, beneficial effect.

Not surprisingly, however, subsidized services that are not carefully designed can have the same negative effects on incentives as financial subsidies. For example, if a project relies on outside technical experts to perform such activities as maintaining accounts, managing marketing efforts, or organizing and mobilizing people to perform some work that benefits the community, these activities are likely to cease once the project has ended. Instead of working for themselves, villagers wait for outsiders to do things for them as they have become accustomed to relying on someone else to do the work, and hence have not developed the necessary skills. In the extreme case, external agencies even discourage villagers from thinking for themselves, suggesting solutions to villagers' problems and offering to subsidize them. This leads villagers to say, 'Tell us what we need', instead of, 'We need this. What do we need to do to achieve it?' (Barbara Adolph, ICRISAT, personal communication).

The key principle here, then, is that subsidized technical assistance should be targeted as much as possible towards helping people do things for themselves as opposed to doing things for them. This is an obvious and often-quoted principle, but it is easy to forget. Sometimes the line between the two is fine, and to avoid crossing it requires great effort. This is because it is usually easier to do something for people than to teach them to do it themselves.

How Subsidies can Undermine Watershed Management Projects

Many Indian government SWC programmes operate through heavily subsidized SWC packages. In these programmes, farmers have little say in the choice of technologies to be used on their fields, but they receive benefits ranging from several days of employment to free fertilizer, seeds and other inputs. The people responsible for implementing the work have little or no say in the project design, and they are evaluated by government auditors on the basis of the level of expenditure and the area covered by the physical structures they construct (government watershed officials, personal communication).[3]

This approach and its results are very similar to those of the compulsory programmes of old. Many farmers adopt the technology not because they like it, but to obtain free inputs or employment. Sometimes the implementing agency, under pressure to achieve quantitative targets, convinces any resisting farmers to accept the work by increasing the subsidy payment (government watershed official, personal communication). In this way all parties are satisfied: farmers receive substantial benefits and officials achieve their quotas. The drawback is that farmers' fields are littered with mechanical structures or vegetative barriers that they do not necessarily want. The structures are removed or left to deteriorate once the project staff depart.

Subsidized technology

Scientists and project managers who are confident in the technologies they develop often design top-down projects with minimal input from farmers. But even if a technology is scientifically sound, it may not suit the needs of farmers, who often have multiple objectives and constraints that cause their preferences to differ from those of scientists (Kerr and Sanghi, 1992; Chambers et al, 1989b; Pimbert, 1991).[4] But if subsidies are high enough – often in India they reach 75 per cent, 90 per cent, or even 100 per cent – then farmers might accept them for reasons unrelated to the characteristics of the technology.

Experience shows that farmers are very particular when it comes to accepting new agricultural technology, particularly in unproductive, risky dryland environments.

Box 17.3 *Subsidized technology in Indian soil and water conservation*

Many soil and water conservation programmes in India subsidize certain pre-approved technologies such as earthen bunds or vegetative barriers. These subsidies make farmers more likely to accept subsidized techniques and less likely to search for less expensive alternative conservation measures. In this way, subsidies inhibit farmers' creativity and slow the development of indigenous knowledge.

An extreme example of this problem is found in hilly, rocky parts of India where the soil is very shallow. One watershed programme operating in such an area subsidized the use of vegetative bunds but not stone bunds; another programme in a similar agro-climatic region subsidized earthen bunds but not stone bunds. In the former case the vegetative barriers could not grow because the stony soil prevented the roots from penetrating. In the latter case, the soil was so shallow that removing it to build earthen bunds would have seriously damaged agricultural productivity.

In both of these areas there was a rich tradition of farmers' own investments in indigenous SWC measures, particularly stone bunds and enclosure walls. In the former area, the project subsidized labour for planting cactus hedges so heavily that it became a highly profitable activity. Farmers responded by planting cactuses next to their existing stone walls. The cactuses served as no more than decoration, but they met the farmers' primary objective of earning subsidy payments.

Achieving progress in agricultural development in these areas means understanding the subtle factors that contribute to farmers' decisions. Scientists and project managers should encourage farmers to test new technologies and consider how to adapt them to suit their needs. Clearly, the complicated task of sorting out the many determinants of farmers' acceptance of new technologies becomes even more difficult when large subsidies tilt the balance in favour of adoption (Box 17.3). Of course, the decision to adopt under these circumstances is likely to be reversed once subsidies are removed, and farmers' suspicions that scientists and programme managers do not understand their needs will be reinforced.

The problem becomes more damaging once farmers become accustomed to heavily subsidized projects that deliver unsuitable technology. In this case farmers anticipate the benefits of subsidies but do not expect anything else of value. In India, many farmers do not take government projects seriously, and they are upset if they do not receive giveaways (Sanghi, 1987). Under these circumstances, heavily subsidized projects are doomed before they begin. Moreover, new projects that attempt to operate without financial subsidies are not welcome: farmers evaluate them in advance on the basis of what giveaways they offer rather than on their merits (Bunch, 1982; Valdes, 1994).

Subsidized inputs

In some watershed projects and on-farm research demonstrations, farmers who adopt SWC practices receive free inputs, such as seeds and fertilizer. The idea behind these giveaways is to demonstrate that improved inputs in combination with SWC measures will result in high yields. Some farmers, however, accept the inputs but then sell them or use them on their irrigated plots rather than on dryland watershed plots (Y. Mohan Rao, ICRISAT, personal communication). As a result, the project fails to achieve the desired demonstration effect, and project officials and scientists obtain no information about farmers' reactions to the technology that might suggest ways to make it more acceptable to them.

Subsidized labour

Some projects subsidize labour devoted to watershed works. In both government and NGO projects, 90 per cent or 100 per cent labour subsidies are common. In fact these subsidies exceed 100 per cent, because they use the legal minimum daily wage of Rs. 22, whereas the market wage in the dry season falls to below Rs. 20 in many rural areas. Therefore 90 per cent of the legal minimum wage actually can be more than the market wage. Not surprisingly, many people eagerly participate in these programmes regardless of what they think of the technology. Formal and informal surveys (Box 17.4) of farmers in various watersheds find that they perceive employment to be the most important project benefit (ICRISAT data, 1994, unpublished).

Subsidies and replicability

Development agencies often list replicability in non-project areas among the objectives of their work. Official documents for large Indian watershed development projects, for example, cite replicability as an important objective (World Bank, 1990; Government of India, 1991). The same documents go on to explain that the projects cover 50 per cent to 100 per cent of the cost of the technologies that they introduce, with farmers contributing whatever is left. These documents contain little or no discussion of the relationship between subsidies and replicability. They

Box 17.4 *Do rural people want conservation measures or employment?*

A group of researchers carried out an informal survey of soil conservation practices in a village in Maharashtra. One of the researchers was from the government and the rest were from elsewhere. When the villagers met the government researcher, they uniformly praised the large government soil conservation programme undertaken 15 years earlier and expressed satisfaction with the contour bunds that it introduced. On the second day of the survey the government official was not present, and the villagers admitted that they did not like the contour bunds but would happily accept them as a means of gaining lean season employment. Once again, subsidies obstructed officials and researchers from gaining information that could help them to improve technologies and project design.

Source: Personal communication with farmers justify subsidies as supporting the demonstration effect, but there is no serious discussion of how subsidies will be phased out. For true replicability, however, phasing out subsidies is critical because funds are not available to provide them except in a limited area and for a limited period.

Because subsidies cannot be made available to everyone – certainly not to all of India's hundreds of millions of farmers – it is probably better not to introduce them in the first place. A watershed project initiated without subsidies obviously faces a more accurate test of replicability than any project supported by subsidies.

Paying for participation

Participatory watershed projects are intended to overcome the problems faced by top-down projects. Participatory planning between farmers and watershed officials is expected to ensure that the technologies selected are both technically sound and acceptable to farmers. Experience shows that this approach is very sound, but if it includes high subsidies, especially subsidies for labour, participation actually can worsen the problem of encouraging farmers to accept useless technology. Two examples illustrate this point (Box 17.5).

These two examples are probably replicated on a daily basis in heavily subsidized, participatory projects in India. The essence of the problem is that subsidies distort incentives so that farmers select the technology made most attractive by the giveaway rather than the one they think is best on its own merits. Project officials too trusting of farmers' wisdom are likely to be fooled in such cases.

Box 17.5 *The consequences of subsidized participation*

A programme in Andhra Pradesh aimed to encourage farmers to build bunds on their land. The project paid the farmers to carry out the work on their own land and allowed them to choose their own technology. Two soil scientists visiting the project in 1993 noticed that on some fields earthen bunds were far larger than necessary, and that they actually did more harm than good by taking scarce topsoil from the field. They also noticed that a large stone structure on the boundary of one field served no apparent purpose. Further investigation suggested that the lure of guaranteed employment led the farmers to build large bunds regardless of their purpose.

The second case concerns a participatory watershed planning exercise held in a drought-prone area of Andhra Pradesh. Under the project, villagers were to be hired to carry out work jointly planned by villagers and project officials. When the villagers were asked to present their plan, they said that enlarging the massive irrigation tank bund was their top priority, even though the tank had filled only three times in the previous ten years. Subsequent investigation revealed that the farmers did not really think that the bund needed to be raised, but they knew that such a large project would employ them throughout the dry season, relieving them from having to migrate to Hyderabad or Madras.

True participation means working together towards a common objective. This will not be possible if the very design of projects creates incentives to mislead and deceive. Subsidies can create such incentives.

Promoting Watershed Development Without an Over-reliance on Subsidies

If subsidies, particularly high subsidies that create employment or target specific inputs or technologies, can create so many problems in watershed development projects, what should be done? First, subsidies should be avoided where there is no obvious justification. Second, where subsidies are justified they should be designed and implemented in such a way as to minimize distortions to incentives.

Designing subsidies with minimal distortions to incentives

In India, high subsidies in watershed programmes are a fact of life, and it will be difficult to remove or greatly reduce them immediately. This is partly because of a 'culture' of high subsidies where no one questions their usefulness, but also because high subsidies are written into national legislation that will not be changed overnight. This means that it is very important to devise ways to reduce the harmful impact of subsidies on watershed programmes.

One way to reduce the harmful effect of subsidies is to require matching labour contributions by landowners on whose land conservation structures are built. The idea is as follows. Farmers may choose their own conservation technology and must build half of a given structure with their own labour (either family or hired). They may then request the conservation programme to construct the second half, according to the design specified by the farmer. The conservation programme would hire the workers under the programme to do so; these workers would be paid only after the farmer certifies that the work is acceptable to him. This approach has several advantages. First, it helps ensure that the technology suits the farmer's wishes and is built according to standards that satisfy him. Second, the farmer never receives any payment, reducing the chances that he will participate in the programme for unexpected reasons.

This approach also offers the important side benefits of helping to organize landless workers and teaching them skills that will increase their self-sufficiency. In particular, labourers may form an association to provide conservation construction services. Payments from the watershed project would be made directly to the association and distributed to its members. Assistance could be provided to the association to develop their business skills and perhaps develop spin-off activities such as revolving credit programmes. More generally, this idea follows the principle of using rural development programmes as leverage to create benefits for disadvantaged groups such as the poor, lower castes and women.

Contributing an input or a technology to a group of families instead of to an individual family is an important step in this direction, particularly if one family's receipt of benefits depends on other families' adherence to agreements made under the programme. This is a well-known principle that contributes to the success of Bangladesh's Grameen Bank, where loans are made to groups of five people, and if one of them does not repay, all five lose access to further credit. Another variation on this principle is known in India as rotational credit, in which loans are provided in sequence to different people in a group. Under this system, the second loan is made only after the first is repaid and so on. Such schemes could be devised under subsidized watershed programmes in India.

However, it is preferable to avoid subsidies entirely where they are not justified economically, rather than try to cope with strategic behaviour by those who receive subsidies. The rest of this section suggests ways to promote watershed development with no subsidies at all.

Institutional innovation to manage local externalities

As stated above, subsidies for watershed management are justified when its private and social returns diverge. Recent evidence from numerous tropical countries, however, suggests that in most cases the benefits of soil and water conservation practices accrue mainly to the farmer who adopts them. The externalities that do exist are usually highly localized: soil erosion in most places does not deposit silt in downstream hydroelectric dams, but rather in neighbouring farms or ponds within the same microwatershed. Similarly, the low application rates of pesticides and fertilizer mean that run-off of poisonous chemicals is not a major problem. If there are no externalities then there is no argument in favour of subsidies; if externalities are small then only small subsidies are justified. In this case, if anyone should pay upstream farmers to adopt soil conservation it is their downstream neighbours, not taxpayers at large.

The idea of 'payments' by one group of farmers to another is not as revolutionary as it first sounds. In fact, it is an old and well-known idea among economists (Coase, 1960). 'Payment' need not mean cash or even kind transactions, but rather some kind of formal or informal compensation mechanism from one group to another (Box 17.6). Such arrangements are sometimes found in common property resource management systems, whereby a group that benefits from a collective management arrangement secures cooperation from a group that does not.

If watershed externalities tend to be small and localized, two principles emerge. First, watershed managers should begin by assuming that there is no need for financial subsidies. If subsidies are justified they may be offered, but justification should not be assumed. Second, external assistance should focus on helping people organize themselves to solve their own problems, and to facilitate access to credit, secure tenure and other factors needed to guide private incentives toward socially productive activities.

Box 17.6 *Spreading the benefits of natural resource management*

A classic example from India is the famous Sukhomajri watershed project, in which landless families received rights to irrigation water in exchange for protecting the irrigation tank catchment area. These families could then sell their water share or use it on leased land (Patel-Weynand, 1997). More recently, the National Tree Growers' Co-operative has adopted a similar approach, giving all households a share in the returns to protecting trees in common forests. Another example from India concerns current efforts in Andhra Pradesh to convert irrigation tanks to percolation tanks (Gangi Reddy et al, 1994). Under certain circumstances there can be substantial benefits from tank conversion, but they are not evenly distributed, so possibly some people who stand to lose have an incentive to sabotage the effort. Success in tank conversion projects therefore requires organizing all the people affected by the tank to ensure that the benefits are distributed in a way that satisfies all of them. No external finance is needed.

Supporting community organizations

Informal village groups can potentially serve as a focal point for efforts to resolve local disputes and mobilize farmers into action. Experience in India suggests that participation in local groups can build villagers' confidence to work collectively, to establish thrift funds to generate capital, to consider new investment opportunities, and generally to become more active (James Mascarenhas, OUTREACH, personal communication; Parthasarathy, 1994). Active local groups can stimulate psychological incentives that previously were stifled by cultural or political constraints. These potential strengths of local groups have nothing to do with external finance. In fact, they present an alternative, more sustainable way to improve the welfare of rural people.

Farmer-to-farmer extension is an offshoot of community organization. Once villagers organize, skilled farmers can serve as extension agents to spread information to their neighbours. They may have more credibility than traditional extension workers because they face the same circumstances as the people they serve. Farmer-to-farmer extension has had favourable results in many countries.

Two principles from these experiences are worth highlighting. First, every community is different, so there can be no single blueprint for designing community organizations. Second, external funds donated to community organizations should be forthcoming only to groups that have already established themselves and demonstrated that they are serious. The funds should be small and should support the costs of organizing, gathering information and spreading awareness; they should not finance giveaways.

Conclusions

In summary, there are good reasons to believe that subsidies are undermining Indian watershed development efforts. This is especially so where subsidies are very high and are tied to employment or to specific technologies that require subsequent maintenance to be useful. In many watershed programmes, subsidies lead farmers to adopt SWC techniques with no intention of maintaining them, and they make it difficult for researchers and project managers to learn what practices farmers accept or do not accept.

Many people in India believe that watershed development should he subsidized simply because so many Indian farmers are very poor and need assistance. However, projects in many countries with similarly poor farmers have removed or substantially reduced subsidies, with favourable results. These countries include Kenya, Lesotho, Niger, Haiti, Cape Verde, the Dominican Republic and the Philippines, to name a few (Lutz et al, 1994; IFAD, 1992; Critchley, 1991; Fujisaka, 1989). In some cases they found that removing subsidies made no difference; in others they found that it improved efforts to encourage conservation. Programmes under SPEECH in Tamil Nadu, Oxfam in Andhra Pradesh, and others have shown that this approach can work in India as well.

Evidence from around the world suggests that farmers will invest in conservation practices when it is profitable for them to do so (Lutz et al, 1994; Tiffen et al, 1994). This suggests that farmers do not need subsidies so much as they need less expensive, more profitable technologies; policies that encourage them to take a long-term perspective in caring for their land, greater awareness of the costs of degradation, and encouragement to organize themselves to invest in conservation (Pretty, 1995).

Even if these enabling conditions are created, there will remain poor people who need assistance to improve their livelihoods. But poor people can be helped in other ways that waste less money and do not distort incentives to invest in conserving natural resources. There is no need to tie poverty relief measures to natural resource conservation efforts.

Likewise, there are alternative ways for the government to support rain-fed agriculture. Gulati (1990) found that Indian agriculture is subject to net taxation even though many inputs are heavily subsidized. This is because price and trade policies reduce output prices and inhibit demand by more than enough to overcome the benefits to farmers of input subsidies. One obvious way to promote investment in more productive agriculture, therefore, is to alter price policies to raise farmers' profits.

Reducing subsidies substantially will be difficult in India. Farmers are accustomed to high subsidies and will oppose efforts to remove them. Also, projects that try to reduce subsidies unilaterally will face difficulties if nearby projects continue to offer large giveaways. For these reasons, removing or substantially reducing subsidies will be very challenging. A concerted effort is needed to eliminate the giveaway mentality if conservation efforts are to have long-lasting and widespread success.

John Pender, Chris Reij, Roland Bunch, Jules Pretty, David Seckler, Barbara Adolf, Doug Clark, Tim Kelley and JK Kiara all offered helpful comments on this paper.

Notes

1. This situation is similar to that in Europe, North America and Japan, where subsidies are politically important and often cause major distortions to the economy. In non-democratic societies, subsidies are politically important where leaders fear being forcibly removed from office rather than voted out.
2. Sometimes subsidy and incentive are used synonymously, but not here.
3. Most of the watershed projects referred to in this paper are deliberately left unnamed.
4. Kerr and Sanghi (1992) explain in detail how differences in Indian farmers' and scientists' priorities cause them to prefer very different approaches to soil and water conservation.

Agri-environmental Stewardship Schemes and 'Multifunctionality'

Thomas L. Dobbs and Jules N. Pretty

Agricultural policy makers on both sides of the Atlantic face new choices about farming and the environment. Member states of the European Union (EU) are shaping policies to implement the Agenda 2000 reforms of the Common Agricultural Policy (CAP), and these reforms are strongly influenced by the concept of multifunctionality. The Rural Development Regulation, designed as a second pillar of the CAP, allows EU member states to shift up to 20 per cent of their CAP funds to rural development and agri-environmental programmes. This could bring a major expansion of environmental stewardship programmes in Europe as EU members redirect funds from commodity support to environmental and rural development objectives. The United Kingdom, for example, shifted 2.5 per cent of all direct payments to farmers under CAP commodity regimes to rural development and agri-environment initiatives in 2001, and plans call for the proportion to rise gradually to 4.5 per cent in 2005 and 2006 (Ministry of Agriculture, Fisheries and Food; Policy Commission on the Future of Farming and Food). The United Kingdom's Policy Commission on the Future of Farming and Food recently recommended an increase to 10 per cent starting in 2004, and that serious consideration be given to increasing the proportion to the maximum 20 per cent 'if substantial CAP reform is not delivered in 2006–07' (Policy Commission on the Future of Farming and Food, p77).[1] Although the US government enacted new federal 'farm' legislation for the years 2002–2007, which greatly expands programmes and funding for conservation (USDA, 2002), debates about agricultural and related environmental policies also continue in the United States.

We draw on our recent review of agri-environmental programmes in the United Kingdom (Dobbs and Pretty) to examine key issues associated with a major expansion of stewardship payment programmes on both sides of the Atlantic. We describe the evolution of agricultural and agri-environmental policies in the United Kingdom and the concept of multifunctionality now driving European dialogue

Reprinted from Dobbs T and Pretty J, Agri-environmental stewardship schemes and 'multifunctionality'. *Review of Agricultural Economics* 26(2), 220–237, Blackwell, Oxford, 2004.

on the next generation of agricultural and environmental policies. Drawing on the United Kingdom experience, we also examine three key issues associated with possible major expansions of stewardship payment programmes: (1) the compatibility of *production support* and *stewardship support*; (2) balancing stewardship payments and *environmental compliance*; and (3) the compatibility of World Trade Organization (WTO) rules with stewardship schemes.[2] We conclude with a discussion of implications of the UK experience for US agri-environmental policies.

Evolution of Agricultural and Agri-Environmental Policies in the United Kingdom

The roots of current agricultural policy in the United Kingdom go back to the 1930s. Like the United States, agriculture in the United Kingdom entered a depressed condition following the collapse of farm prices after World War I, and it remained so as the industrial world sunk into depression in the 1930s. Price supports for many agricultural products had been put in place by 1932. As the likelihood of United Kingdom involvement in the European conflict grew in the late 1930s, it was apparent that the United Kingdom could be blockaded and food supplies threatened. Consequently, there was a massive effort to intensify agricultural production. Plans, incentives and mandates were put in place for farmers to convert pastures to crop production. Although price controls were in effect during the war, support prices were raised to help provide the money needed to intensify production. Farmers who failed sufficiently to comply with the intensification plans mandated for their farms could be, and sometimes were, evicted. The various policies and initiatives began a major transformation of agriculture in the United Kingdom (Potter; Wormell).

The United Kingdom determined that agriculture would not be allowed to collapse again, as it had after World War I. The principal objectives of the 1947 Agriculture Act were to increase food production and combat the chronic balance of payments deficit. In this and subsequent Acts, the United Kingdom government recommitted itself to an intensified and modern agriculture. Policy instruments included plowing grants, price subsidies for crop and livestock products, grants for field drainage and hedgerow removal and subsidies for fertilizers (Pretty, 1998). Similar policies were put in place elsewhere in Europe, and the policies began to take on greater uniformity with initiation of the CAP by the then Common Market in 1958. Much of the United Kingdom's domestic agricultural support was conditioned by the CAP following entrance into the European Community in 1973. Like US agricultural support policies, the CAP was effective in stimulating food and fibre production. However, this abundance came at increasingly high budgetary and environmental cost.

In recognition of the mounting problems with modern, intensive agriculture, policy reforms started in Europe in the mid-1980s. The Environmentally Sensitive Areas scheme was the first agri-environmental programme in the EU, launched in the United Kingdom in 1986. The next major UK agri-environmental programme was the Countryside Stewardship Scheme, established in 1991. The 1992 Mac-Sharry CAP reforms began to weaken the links between production and farm income support, and were followed with financial assistance packages to UK farmers to convert to organic agriculture or accomplish a variety of environmental outcomes.

Multifunctionality

Building on the experiences of the 1980s and 1990s, EU member states are now shaping a new generation of agri-environmental policies based upon the concept of multifunctionality (Organisation for Economic Co-operation and Development). Agriculture is inherently multifunctional – it does more than just produce food, fibre, oil and timber (Food and Agriculture Organization, Whitby). It has many functions or purposes, thereby potentially producing a wide range of outputs or services.

Agriculture that depletes organic matter or erodes soil while producing food externalizes costs that others in society must bear; but one that sequesters carbon in soils through organic matter accumulation contributes to both the global good by mediating climate change and the private good by enhancing soil health (Pretty et al, 2000, 2002). Similarly, a diverse agricultural system that protects and enhances on-farm wildlife for pest and disease control contributes to wider stocks of biodiversity, while simplified modernized systems that eliminate wildlife do not (Costanza et al, Doran and Werner, Pretty et al, 2001, Pretty, 2002).

Multifunctionality suggests agriculture can deliver valued nonfood functions that cannot be produced by other economic sectors. Much of the apparently 'natural' biodiversity in Europe is the result of centuries of farming, and agriculture has created and shaped the landscape and countryside. There are many other positive side effects of agriculture, including values derived from aesthetic appreciation; recreation and amenities; water accumulation and supply; nutrient recycling and fixation; wildlife, including agriculturally beneficial organisms; and storm protection and flood control. The idea that agriculture provides these other types of goods and services is not new, of course, and, in itself, is not controversial. The controversies surround how this concept is translated into policies.

Several major challenges face policy makers in restructuring agricultural support based on the multifunctionality perspective. With multifunctionality centre-stage in EU agricultural policy discussions, support to farmers increasingly will be tied to stewardship and other social objectives, rather than to food and fibre production. Admittedly, agricultural policies have frequently served several public policy objectives. Figure 18.1 illustrates how different agricultural policies rest along intersecting continuums. Some policies serve primarily to support food and fibre production objectives, some support primarily stewardship (environmental) objectives and others support particular social objectives. In addition, some may support a combination of two or all three of these objectives. The challenge to multifunctionalists that we focus on in this article is how to make the transition from production (top of the triangle in Figure 18.1) to stewardship policies (lower right-hand corner).

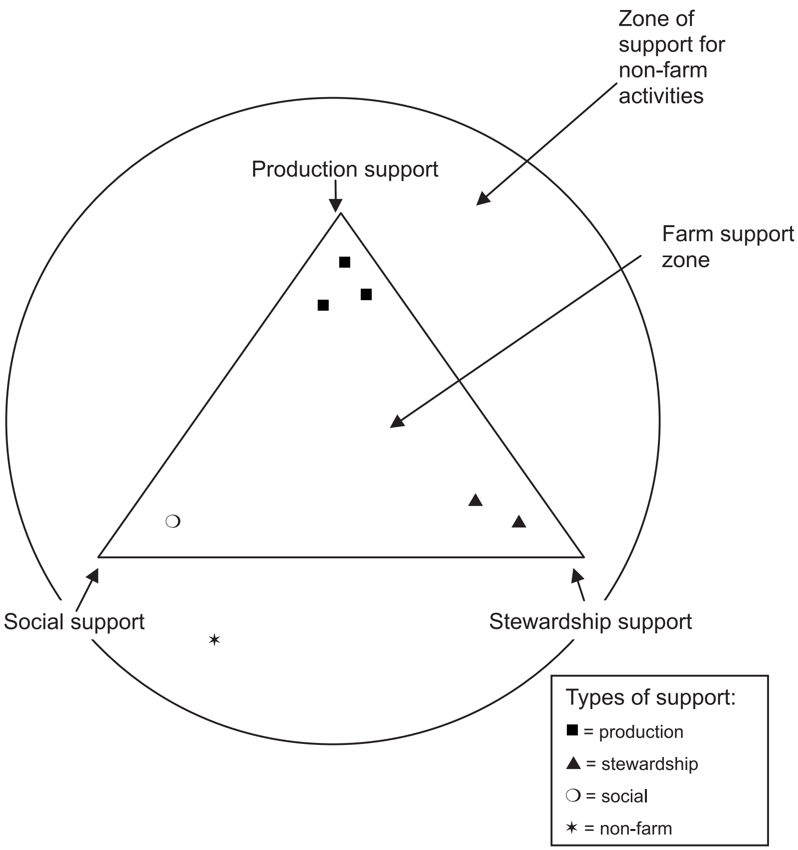

Figure 18.1 *Location of agricultural/rural support according to production, stewardship and social objectives*

In addressing this challenge, consider exactly what kinds of policies tend to be clustered in the different corners of Figure 18.1. Major examples are listed in Table 18.1. Various kinds of grain and oilseed price supports used in the EU and the United States during the last half of the 20th century clearly served primarily to increase food and fibre production. In the United Kingdom, a number of those policies initially were intended to increase production of food commodities, but they also had the social objective of supporting farm incomes. In the United States, price support policies initiated in the 1930s were intended primarily to achieve social objectives of maintaining farm income and a family farm structure of agriculture. However, because the support mechanisms were so closely tied to crop production, these policies are represented by small boxes close to the production support corner of Figure 18.1. In other words, de facto, the policies tended to support an objective that increasingly was not a priority in industrialized societies in the late 20th century.

Livestock headage payments in the EU also have been explicitly tied to levels of production. The US deficiency payment policy of the 1980s and early 1990s,

Table 18.1 *Typology of public policies/schemes according to objective with which they are most closely associated*

Production support	*Stewardship support*	*Social support*	*Support for non-farm activities*
Price supports	Organic Farming Scheme[a]	Fully decoupled income support payments	Support for rural infrastructure
Livestock headage payments	Tir Gofal[a]	Beginning 'small-farmer' loans	
Deficiency payments	Arable Stewardship Scheme[a]	'Capping' price or income support by farm size or income	Education in rural areas
Crop insurance	Norfolk Area Land Management Initiative[a]	Support for farmers' markets	Rural health care
Income insurance	Countryside Stewardship Scheme[a]		
	Environmentally Sensitive Areas Scheme[a]		
Area payments	Countryside Premium Scheme[a]		
	Integrated farming schemes[a]		
	Nitrate Sensitive Area Scheme[a]		
	Conservation Compliance		

Note: [a] UK schemes.

based on the differences between target and market prices of various commodities, had the social objective of supporting farmers' incomes but was still closely tied to production. Therefore, we consider that policy also to have been more closely tied to the partially outmoded production objective than to the actually intended social objective of increasing farmers' incomes. US crop insurance schemes in the 1980s and 1990s, and income insurance schemes piloted in the late 1990s, represent some movement along the continuum from production support toward social support. However, unless very carefully designed, they risk being tied primarily to levels of production of particular commodities. The EU's area payments, under the Arable Area Payments Scheme, are less tied to production than have been its price support policies. However, they still tend to be closer to the production end of the triangle in Figure 18.1 than to social or stewardship support.

We have examined a range of UK policies of the 1980s and 1990s that are closer to the stewardship support corner of the triangle (Figure 18.1 and Table 18.1). The Organic Farming Scheme and its predecessor, the Organic Aid Scheme, were clearly tied to particular stewardship farming systems, as were other schemes in the United Kingdom, including Tir Gofal in Wales. As we read down the stewardship support column in Table 18.1, some policies listed also have social or production elements. Conservation compliance, as incorporated in farm policy in the United States since the mid-1980s, is designed to support stewardship objectives. Commodity program benefits are conditioned on environmental performance on highly erodible cropland (Heimlich and Claassen). Most farmers have come into compliance by altering particular production practices, rather than by substantially altering their farming systems.[3] Therefore, we might think of the conservation compliance policy as being somewhere on the continuum between production and stewardship (Figure 18.1).

Transatlantic policy dialogue about multifunctionality is hindered by the often-differing European and North American values with respect to agricultural landscape and habitat.[4] Europeans value the managed landscape that has evolved over the centuries, whereas many North Americans place high value on 'wild', non-agricultural settings. There are also differences in the values put on the types of animal and plant biodiversity. Birds for hunting are highly valued in the United States, for example, whereas a wide variety of farmland bird species are valued for viewing in the United Kingdom. The basic concept of multifunctionality is the same on both sides of the Atlantic, although it manifests itself differently. Appreciation of 'traditional' farm and ranch landscapes, especially those near urban areas, is likely to grow in the United States (Hellerstein et al).

Support for rural development that is more broadly based than on-farm activities alone is an important element in the emerging EU multifunctionality debate. These 'non-farm' rural development activities are represented by the space outside the triangle but within the circle in Figure 18.1. A few broad examples of such activities are listed in the last column of Table 18.1. The first example consists of government support for communications, waste treatment and other kinds of physical infrastructure that make living and operating non-farm businesses in rural areas attractive and affordable. Non-farm businesses include ones related to agriculture, such as food processing operations. The other two examples listed consist of support for human and social capital related to education and health care in rural areas.

The focus on multifunctionality, or multiple objectives related to agriculture, is not an attempt to refute the economic notion that some policy tools may be more efficient than others in achieving different objectives or goals (Claassen et al). On the contrary, a multifunctionality approach calls for policy to be much more explicit about what we want from agriculture than has usually been the case. By so doing, analysts can more clearly identify policy tools and scenarios likely to result in either complementarity or competitiveness between agriculture's different functions.

Rather than examine the entire range of relevant policy tools, we focus in this article on positive incentive policies in the form of 'stewardship payments'. This type of policy tool is intended primarily to enhance agriculture's performance with respect to positive environmental functions, but it also can have intended or unintended effects on production and social functions. Other potential policy tools designed primarily for environmental functions, such as environmental taxes and regulations, have been extensively analysed elsewhere (e.g. Pretty et al, 2001; Ribaudo et al).

Issues Emerging from the UK Experience

Several issues emerge from examining the UK experience, and its growing emphasis on multifunctionality, that have bearing on proposals and plans to substantially expand stewardship payment programmes in Europe and the United States.

Compatibility of production support and stewardship support

Much remains to be done to completely decouple income support for farmers from production. Although there have been significant first steps in decoupling under the EU's CAP, strong incentives remain for farmers in the United Kingdom's main arable areas to continue farming intensively. UK agri-environmental schemes often have not been financially attractive to highly productive, intensive arable farms (Potter; Baldock and Mitchell). Cobb et al indicate that organic farming systems have tended to be disadvantaged relative to conventional systems in the United Kingdom because the clover/grass leys that are typical in organic rotations did not qualify for CAP arable area payments. If the ley was grazed or put up for hay or silage, it did not qualify as set-aside.[5] Bailey et al also found that eliminating or decoupling government support payments and eliminating set-aside requirements would enhance the profitability of 'integrated' crop systems relative to 'conventional' systems in the United Kingdom. Farmers in the United Kingdom's arable regions still benefit too much from production-related CAP supports to take up the higher tiers of agri-environmental schemes, and to diversify with crop rotations.

Well-intended calls for stronger safety nets in the United Kingdom tend to venture onto a slippery slope toward the area of production support. In an otherwise generally excellent discussion of policy options for UK agriculture, a report of the Royal Agricultural Society of England (RASE) justified the need for a stronger safety net, but it was vague about how such a system would be constituted. The report stated, 'any safety net should set a floor or minimum price, but is by definition coupled to production' (Royal Agricultural Society of England, p17). Authors of the RASE report suggested the possibility of using crop and revenue insurance schemes like those being tried in the United States, to strengthen the safety net for UK farmers as conventional CAP price supports are phased out. However, these schemes can inadvertently encourage overly specialized production systems if coverage is too narrow or premium subsidies are too high for particular crop or livestock enterprises. Subsidized crop insurance tends to result in expansion of cropland area (Wu). Cautions about the potential distorting effects of government-backed insurance schemes are noted in the USDA's policy statement, *Food and Agricultural Policy: Taking Stock for the New Century* (USDA, 2001).

Potter and Goodwin stress that merely abandoning production supports is unlikely to accomplish the range of stewardship objectives desired in Europe. It could, indeed, lead to less intensive production (at least after a time), thereby reducing negative externalities related to inorganic fertilizer and pesticide use. However, the overall effects on the range of features that Europeans desire in their managed agricultural landscapes are less clear. Most of the beauty and biodiversity of landscapes in the United Kingdom and elsewhere in continental Europe depend on the continuation of active farming. It is restoration or maintenance of a certain kind of farming that is desired in Europe. Liberalization of farm policy, by itself, could 'wipe out much of the human capital necessary for the effective conservation of the European countryside' (Potter and Goodwin, p291). Stated another way, decoupling of subsidy payments from specific crop and livestock commodities is a necessary, but not sufficient, condition for achieving landscape-based environmental objectives. Stewardship programmes are required to counterbalance some of the economically depressing effects that more market-oriented farm policies could have on European agriculture.

Balancing stewardship payments and environmental compliance

A critical issue facing policy makers is how to specify which environmental standards should be required without directly compensating farmers and which they should be compensated for achieving. A threefold categorization is useful in thinking about this issue (Dwyer et al). The base category consists of farming practices covered by regulations, such as restrictions on pesticide applications near waterways or on nutrient applications in the United Kingdom's Nitrate Vulnerable Zones (NVZs). The next category consists of good practices that go beyond regulatory requirements, but for which there are no agri-environmental payment programmes. Examples in England include 'retaining traditional field boundaries, or maintaining green cover over winter on erodible soils' (Dwyer et al, p32). The third category contains practices providing environmental services covered by incentive-based compensation schemes. *Cross-compliance* requirements for farmers receiving CAP production support payments could be applied to practices in either of the first two categories.

The debate about which farming practices belong in each category is both philosophical and economic. In essence, this is a debate about whether various agricultural practices that might be carried out for environmental purposes should be viewed as (1) avoidance of negative externalities or (2) production of positive externalities or public goods. What is the baseline, above which agriculture is providing positive environmental externalities and below which agriculture is *harming* the environment (producing negative externalities)? The answer in any given situation has important implications for public policy. Bromley and Hutchinson stress that this question cannot be answered objectively. The answer is inherently political, being based on public perceptions and political processes specific to time and place that determine property rights and who should provide and pay for particular environmental or social goods from agriculture.

An evolution of thinking on this question is illustrated by UK policy regarding nitrate contamination of water by agriculture. For a number of years during the 1990s, the United Kingdom implemented a Nitrate Sensitive Areas (NSAs) scheme that centred on payments to farmers for reducing or eliminating nitrate contamination. This voluntary scheme had similar features to the former Water Quality Incentive Program (WQIP) and the current Environmental Quality Incentives Program (EQIP) in the United States. Although the NSA scheme seemingly was successful (Lord et al), it is being phased out in favour of the NVZ programme. The NVZ programme is a mandatory action programme of measures for controlling nitrate concentration in surface and groundwater in vulnerable areas. Thus, the emphasis has shifted from voluntary to mandatory measures. This implies that nitrate contamination is now viewed as a negative externality, in contrast to the earlier implied view that avoidance of nitrate contamination constitutes provision of a positive externality (clean water).

United Kingdom environmental groups have argued that some environmental conditions should be attached to the CAP support payments farmers receive, i.e. that there should be cross-compliance (Potter and Goodwin; Royal Agricultural Society of England). The UK government has been considering new cross-compliance measures (Performance and Innovation Unit; Ministry of Agriculture, Fisheries and Food; Policy Commission on the Future of Farming and Food).

Environmental cross-compliance in the United Kingdom currently exists in the following:

> (*a*) The receipt of all headage payments for beef and sheep under the Sheep Annual Premium Scheme (SAPS), Beef Special Premium Scheme (BSPS), Suckler Cow Premium Scheme (SCPS), Extensification Premium and Hill Livestock Compensatory Allowances under the Less Favoured Area (LFA) scheme, is conditional on not causing significant overgrazing of the land used by livestock upon which these payments are claimed.
>
> (*b*) The receipt of Arable Area Payments, including set-aside payments, has been made conditional on farmers obeying certain conditions for the management of set-aside land … to protect habitats and species in cropped landscapes. Conditions include the retention of traditional field boundaries adjoining set-aside land, and restrictions on the timing of certain operations on the land, including ploughing and spraying, in order to minimize damage to ground-nesting birds and other species which may breed or feed in set-aside fields (Dwyer et al, pp25–26).

Dwyer et al recommended that the UK government consider several additional cross-compliance measures. One would reinforce key environmental regulations with cross-compliance conditions, such as regulations related to hedgerow and groundwater protection. A second measure would make it a general duty for farmers to observe major codes of good agricultural practice already in place in the United Kingdom. The third measure would require that farmers draw up a specified whole-farm plan. This might consist of a whole-farm conservation plan or report similar to those of the Farming and Wildlife Advisory Group in England and Scotland. The intent, however, at this stage, would not be to require farmers to implement all the plans' suggested actions. Finally, Dwyer et al recommended consideration of a cross-compliance measure requiring margins of specified widths around all fields eligible for Arable Area Payments.

As long as CAP support payments remain high, cross-compliance measures effectively serve as regulations for most farms eligible for payments. Therefore, environmental services resulting from cross-compliance are obtained with substantially less government budgetary cost than through expanded stewardship payment programmes. However, if and when production-related support payments dramatically decline or disappear in the EU, cross-compliance loses much or all of its leverage. Therefore, long-range agri-environmental planning must be based on a collective vision of which environmental conditions or outputs should be obtained through regulations and which ones should be purchased from farmers through stewardship payments.

That collective vision will emerge from interpretations and applications of the multifunctionality concept. It is quite possible, and not necessarily inconsistent, to simultaneously move in two different directions. One, exemplified by the current UK direction for nitrate externalities, requires farmers to avoid practices that clearly have adverse effects on society. The policy mix in such a polluter-pays approach could include a combination of regulations and taxes on practices and inputs that cause public harm.

The other direction, which has dominated in Europe, is to pay farmers for adopting practices that produce public goods and positive externalities – the so-called *provider-gets* principle. With this perspective, producing wildlife habitats or scenic vistas is considered to be producing a good, rather than avoiding a bad. The multifunctionality concept provides a rationale for public compensation, rather than regulation, at least some of the time. Whether a particular agricultural practice or system is viewed as producing a good or preventing a bad is clearly a matter of perspective. In the real world of policy, we are likely to see public support for paying farmers to do some things that are good for the environment, while public sentiment insists on uncompensated regulations to prevent certain practices or systems considered bad for the environment (e.g. see Policy Commission on the Future of Farming and Food).

Compatibility of world trade organization rules with stewardship schemes

As European governments shift more of their agricultural support to agri-environmental schemes, increasingly complicated issues of compatibility with WTO rules are emerging. Some in the US agricultural industry, for example, have felt that multifunctionality may be merely a protectionist ploy to continue EU subsidies under the guise of environmental protection. European economists, however, have begun systematically to examine the conditions under which stewardship payments – configured within a multifunctionality framework – may be consistent with economic efficiency criteria and what this may imply for world trade rules.

The Uruguay Round 'Agreement on Agricultural Trade' set out a series of decoupled payments that are considered compatible with WTO rules. This zone of compatibility is the so-called 'Green Box'. Payments for environmental programmes are among those that fall in the Green Box (Swinbank). However, it is not entirely clear which policies the WTO will consider to be in the Green Box as Europe advances new policies under the multifunctionality banner. Figure 18.1 seeks to bring clarity to this issue. An agri-environmental policy that is fully decoupled from production support would be in the lower right-hand corner. Such a policy would advance society's environmental goals – say, by producing positive externalities or reducing negative ones – without also increasing production. Stewardship payment schemes that provide incentives to restore hedgerows and increase field margins are good examples.

Some other agri-environmental policies are likely to be more controversial with respect to Green Box classification. There is considerable concern in Europe that the movement toward free trade, with farmers having to depend on world market prices, could 'lead to environmental decline as farmers abandon unprofitable marginal land' (Latacz-Lohmann and Hodge, p43). The European idea of managed countryside is one in which, over some range, the joint production of food and environmental goods is largely complementary, rather than competitive. If agricultural support falls too low, it may no longer be economically viable for farms in some areas to produce either conventional agricultural commodities or the kinds of rural landscape and habitats European societies value (Cahill; Latacz-Lohmann and Hodge; Swinbank). In such a situation, does an agri-environmental scheme designed to maintain multifunctional agriculture, in the Cotswold region of the west of England, for example, fall inside or outside the WTO's Green Box? A number of agri-environmental schemes in Europe may be like this – towards the stewardship support corner of Figure 18.1, but part way up the continuum running to production support. 'New World' trade negotiators tend to favour wilderness landscapes for environmental enhancement, and joint production is generally not an issue with those landscapes; 'Old World' (European) negotiators, however, place more value on lived-in, working rural landscapes (Latacz-Lohmann and Hodge).

Ervin and Mullarkey et al stress the importance of using policy instruments that minimize *trade distorting* effects when efforts are made to sustain or enhance agriculture's positive environmental functions. For example, simply maintaining an area in agricultural production may provide the desired agricultural landscape, while a higher level of crop and livestock production in that landscape may produce no additional environmental amenity (in fact, it may even decrease the amenity value) but it is more *trade distorting*. In fact, poorly designed agri-environmental programmes could inadvertently even bring more land into commodity production (Heimlich and Claassen). Latacz-Lohmann and Hodge suggest a number of ways for determining which kinds of agri-environmental policies legitimately belong in the Green Box. In essence, these suggestions call for policies that focus primarily on stewardship support while limiting, to the extent possible, *trade-distorting* commodity production and price effects. Payments should be coupled to stewardship and decoupled from production, even though, in practice, stewardship payments will sometimes cause production to be higher than it would be otherwise.

A related issue is how additionality is to be interpreted. A provision of the Uruguay Round Agreement on Agriculture limits agri-environmental payments to the extra costs of complying with government programmes (Latacz-Lohmann and Hodge). The UK Treasury also has insisted on additionality. Except in the Environmentally Sensitive Areas, simply maintaining habitat is not considered sufficient to qualify for agri-environmental payments. There must be additional public benefits beyond what is already provided by the farmer without payment. This results in troublesome contradictions: farmers who had previously removed hedgerows would be paid to restore them, but those who had maintained hedgerows at their own expense would not qualify for additional payments (Royal Agricultural Society of England). Similar contradictions plague US conservation policy. As Claassen et al (p37) indicate in their analysis of alternative agri-environmental payment approaches for the United States, if 'bad actors' can receive payments for modest environmental improvements while 'good actors' are excluded, farmers 'will be discouraged from taking any unsubsidized action that improves environmental performance'.

This issue will need to be addressed if agri-environmental policy is going to take centre stage. In our view, fairness and consistency require that all farmers are equally eligible for payments for providing particular environmental services, even if they already had been providing the services without compensation. This position does not imply that every environmental service or externality-avoidance merits compensation. It simply means that if one farmer is eligible for compensation to begin providing a service, every other farmer (in like areas and circumstances) already providing the service also would be eligible.[6] Therefore, additionality would be interpreted with respect to *normal* farming practices, not with respect to particular farms. This approach would involve specification of 'reference levels' similar to those described by Claassen et al:

> Reference levels could vary with soil type and topography, geographic region, or all of these factors. While a reference level is not an environmental baseline – it would not be

> specific to a particular farm or field – it would reflect the cropping patterns and production management or conservation practices generally in place under homogeneous soil and climate conditions. (Claassen et al, p35)

For example, if agri-environmental programmes provide payments for farmers in designated regions to use organic practices or utilize forage or green manure legume-based crop rotations, all farmers in those regions would be eligible for payments, including those who already had been farming with such systems. If this position is ruled incompatible with additionality interpretations of the WTO or other governing bodies, then those interpretations will need to be rethought. Latacz-Lohmann and Hodge suggest that Green Box criteria need to allow farmers to be paid for providing non-market environmental benefits above some reference level. If that principle is accepted, there would seem to be no valid basis for the WTO to distinguish between farmers who were already providing such benefits and those who begin providing the benefits following the initiation of a stewardship payment scheme.

An agri-environmental policy that qualifies farmers for payments who already are carrying out eligible practices or meeting established environmental criteria does not necessarily make life easy for policy makers and agri-environmental agencies. First, of course, are the budgetary implications. Making everyone eligible would be expected to add to the short run expense of providing a particular set of public environmental services. However, in the long run, government costs might not be greater, because farmers would come to see that bad environmental behaviour is not rewarded or, conversely, good environmental behaviour is not penalized.

Second, establishing what is normal and what are like circumstances is not easy, in practice. Normal rotations for one set of farms in a local area, for example, may vary from what is normal for other farms in the same vicinity because of subtle differences in biophysical circumstances. There are substantial administrative costs in taking all of these circumstances into account to establish and implement agri-environmental programme eligibility criteria. Using eligibility criteria derived from comparisons of what is additional relative to normal farming practices is feasible, but not without difficulty.

Agri-environmental issues are on the agenda for the new round of WTO negotiations that was approved in Doha, Qatar in November 2001. Even under current WTO rules, policies to support environmental objectives in agriculture are allowed if they are only 'minimally trade distorting' (Normile, p80). How much is minimal is likely to be contested.

Implications for US Policies

In spite of some differences in perspective, 'the European Union and the United States are coming closer together in the policy issues that they will have to address'

(Blandford, p17). Further, substantial policy reforms are required on both sides of the Atlantic to accomplish shared goals. This means that European and North American policy makers must be willing to learn from the past and from one another as they develop new directions for agri-environmental policy.

There was much discussion and debate about the scope and form of conservation and agri-environmental programmes in the process of developing the latest US 'farm bill', the Farm Security and Rural Investment Act of 2002. This Act authorizes a ten-year expenditure plan for the US agricultural sector that calls for an 80 per cent increase in spending on conservation and environmental programmes (compared with a baseline projection under previous programmes and policies) (USDA, 2002). However, production-related price and income supports also have been continued and expanded, with expenditure increases over ten years expected to be nearly four times the amount of conservation expenditure increases.[7]

It seems evident from experiences on both sides of the Atlantic that for agri-environmental policies to be fully effective, the decoupling of income supports from production must be completed. Such a decoupling clearly did not come about in the United States's 2002 farm bill. If anything, there was some recoupling, in that a new system of counter-cyclical payments tied to target prices and updated base acres and crop yields was established (USDA, 2002). This support mechanism is very similar to the old target price/deficiency payment mechanism done away with in the 1996 farm bill.

Even under the 1996 farm bill – with its planting flexibility provisions, as well as conservation compliance provisions going back to the 1985 farm bill – Corn Belt farmers remained too tied to production-related supports to diversify out of the narrow and inherently chemical-intensive corn-soybean rotation. Between 1996 and 2000, soybean acreage increased in several Corn Belt States, while corn acreage stayed about the same or decreased slightly (Commission on 21st Century Production Agriculture). Some land shifted from continuous corn production to the corn-soybean rotation, but there was little shift to more diverse rotations incorporating forage or green manure legumes.[8] Although many Corn Belt farmers have adopted 'best management practices' intended to reduce environmental damages, they had little impact on inorganic fertilizer and pesticide loadings (Caswell et al). Since the structure of agriculture has evolved over the last several decades toward larger farms and fewer market outlets for forages and other products of diverse crop rotations (Dobbs and Dumke; Dumke and Dobbs), decoupling alone may be insufficient to bring about much increase in diversity and reduction in chemical intensity – unless, perhaps, one is thinking in decades, instead of years. This is true in both England's East Anglia and the American Corn Belt. The continuation of major production-related supports under both the EU CAP and US farm bills makes it much more expensive and difficult for agri-environmental programmes to be effective.

At the same time, it must be recognized that dramatic reductions in, or actual elimination of, price or income supports in the United States could result in the sacrifice of some environmental gains achieved as a result of conservation compliance if there is not sufficient expansion of regulations or stewardship payments (or both). The evolution of UK agri-environmental policies toward nitrate contamination illustrates the kind of decisions that will need to be made if there is less US reliance on conservation compliance in the future. As described previously in this article, that evolution implied a more clear delineation of which kinds of agricultural externalities will, for policy purposes, be considered subject to the polluter-pays principle (in this UK case, nitrate contamination) and which ones will be subject to the provider-gets principle. If conservation compliance were to lose its leverage in fostering the kinds of basic soil conservation and wetland protection called for in US farm bills since 1985, it would be necessary to decide if the former compliance levels really are baselines, subject to uncompensated regulations, or if they are to be maintained by expanded stewardship payment programmes.

The most significant expansion in stewardship payment programme funding in the 2002 US farm bill is for the EQIP, but the most significant new programme form is the Conservation Security Program (CSP). This programme has features similar to some of those that have existed in UK agri-environmental programmes, with different payment 'tiers' based on the nature and scope of environmental practice or system changes. Unlike the Conservation Reserve Program, which takes land out of conventional crop and livestock production in order to focus exclusively on environmental goods, the CSP is designed for *working lands*. The CSP constitutes an attempt to foster multifunctionality by leaving land in crop and livestock production and providing stewardship payments for the use of practices and systems intended to reduce negative environmental externalities or, conversely, increase positive ones.

Tier I of the CSP, the lowest tier in terms of conservation requirements and payment rates, focuses primarily on individual practices. Tier II, with payment rates higher than those for Tier I, requires enrolled farmers to deal with 'at least one significant resource of concern for the entire agricultural operation' (Conservation Security Program, pp6–7). The highest payment rates are for Tier III, which requires application of a 'resource management system that meets the appropriate nondegradation standard for all resources of concern of the entire agricultural operation' (Conservation Security Program, p7). Based on the UK experience with tiered agri-environmental schemes, one of the major challenges to US policy makers will be to induce farmers in the more productive agricultural areas into the higher tiers, especially, in this case, Tier III. Given the continuation of high price and income supports tied directly or indirectly to narrow, intensive crop systems, it is likely to prove either difficult or very expensive to induce participation in whole-farm resource management plans that actually involve very much change in farmers' systems. Changes involving resource conserving crop rotations (listed among the CSP's eligible conservation practices) could prove especially difficult to induce.

Although the whole-farm orientation of the CSP's Tier II and (especially) Tier III represents an European-like broadening of US agri-environmental policy, the legislative language implies a more narrow multifunctionality orientation than some of the latest European agri-environmental schemes (Conservation Security Program). The CSP could be used to foster bird habitat and biological diversity, as in UK agri-environmental schemes; eligible practices include fish and wildlife habitat conservation, restoration and management. However, rural landscape priorities, which have been central to major UK agri-environmental schemes, are not particularly evident in other types of conservation practices (nutrient management, integrated pest management, water conservation and water quality management, energy conservation measures, contour farming etc.) listed as appropriate for CSP contracts. Moreover, the legislative language does not suggest much emphasis on promoting regional social and economic objectives, as do recently introduced European schemes like England's Land Management Initiatives (Countryside Agency) and France's Contrat Territoriale d'Exploitation (CTE, or Territorial Contract of Farming) (Dwyer, 1999, 2000). Such an emphasis does not seem precluded, though, as enhanced CSP payments are allowed if participating farmers 'address local conservation priorities' or participate in 'a watershed or regional resource conservation plan that involves at least 75 per cent of producers in a targeted area' (Conservation Security Program, p10). If the CSP were to evolve in the direction of a much broader multifunctionality, it would be valuable for US policy analysts to monitor lessons learned during implementation of relatively new schemes like the Norfolk Area Land Management Initiative, which combines regional and whole-farm planning in the east of England.

The research on which this article is based was initiated while Thomas Dobbs was a Fulbright Scholar at the University of Essex's Centre for Environment and Society, in England, in 2000. In addition to support from a Fulbright Scholar grant, research support has been provided by South Dakota State University's Agricultural Experiment Station. This article has benefited from a number of constructive suggestions made by the RAE's editors and anonymous reviewers. Of course, we remain responsible for interpretations and opinions expressed in the final version of the article.

Notes

1 These percentages are shifts of funds from traditional production-type CAP supports to rural development and agri-environmental programmes, and do not represent the total percentage of the agricultural budget devoted to rural development and agri-environmental programmes. At the present time, the second CAP pillar – covering rural development and agri-environmental measures – commands only around 10 per cent of the overall EU CAP budget (Baldock and Bennett).

2 See Dobbs and Pretty for a more complete discussion of issues associated with the UK experience, including: opportunities for programmes to contribute jointly to social and stewardship objectives; capitalization of scheme benefits into land values; and how to gain from bottom-up planning and subsidiarity.
3 See Dobbs for a distinction between changes in farming practices and changes in farming systems.
4 Bromley refers to these as amenities and habitat.
5 Based on perceived benefits to the environment, organic agriculture has been aggressively promoted under the United Kingdom's Organic Farming Scheme. Preliminary case study evidence reported by O'Riordan and Cobb supports the existence of at least some of those perceived benefits, relative to 'conventional' agriculture.
6 This does not imply that farmers in all regions of a country would necessarily qualify for given environmental practices or performance. For example, farmers utilizing a particular agricultural practice or system might qualify for incentive payments in a watershed threatened by soil erosion, but not qualify in another watershed or region of the same country if it is not so threatened. That is a separate issue of 'spatial targeting' (Claassen et al).
7 Preliminary estimates by the Food and Agricultural Policy Research Institute (FAPRI) indicated that net outlays on commodity programmes could increase by $49.7 billion over ten years (compared with a baseline with previous farm bill provisions), and the projected increase was $13.2 billion for conservation programmes (United States Senate Committee on Agriculture, Nutrition & Forestry).
8 It has long been known that cropping systems that include regular rotation of forage and green manure legumes contribute greatly to the creation of the soil's natural capital (Balfour; Daily; Doran and Werner; Peterson et al; Power; Pretty, 1998, 2002).

Ways Forward? Technical Choices, Intervention Strategies and Policy Options

Camilla Toulmin and Ian Scoones

Introduction

This book has emphasized the importance of taking local contexts seriously. The case studies have revealed the importance of dynamics and diversity in all farming settings across all three countries. Some of the key findings are summarized below.

- Farmers have criteria for classifying soils, such as their workability, inherent fertility, suitability for certain crops, responsiveness to particular inputs and water-holding capacity. Farmers actively manage their soils in ways that build on these characteristics with the aim, over time, of thus improving their value for crop production.
- Africa's farming systems are highly diverse. This diversity is an important feature at all scales. At household level, farmers manage this diversity by different land use practices, choice of crop and input levels. Diversity at the level of the village landscape is exploited through use, for example, of low-lying areas (variously known in the study areas as *bas fonds, vleis, dambos*), for moisture-loving crops, upland sands for millets and groundnuts, and gravelly slopes for grazing and woodland. Farmers value such diversity since it provides greater protection against the risk of crop failure. Diversity at national level is seen in the differential development of areas considered of high and low potential, infrastructural investment and ease of access to important markets.
- Farming systems are dynamic, responding to a range of internal and external pressures. Reliance on data from nutrient balances provides only a snapshot at one point in time, from which the direction and evolution of the farming system in question are hard to determine. There is no single pathway being followed by all farmers in a given site, but rather an array of directions being

Reprinted from Toulmin C and Scoones I. 2001. Ways forward? Technical choices, intervention strategies and policy options. In Scoones I (ed) *Dynamics and Diversity*, Earthscan, London, pp176–208.

taken depending on their circumstances. Farmers are constantly seeking new strategies as problems arise or new opportunities develop.

- Farmers' management of soil nutrients depends on a range of socioeconomic factors. Access to livestock, labour, credit and markets are of particular importance in explaining which farmers are best able to maintain and improve the fertility of their soils. The household remains central to the management of the farm and the mobilization of resources, such as labour and capital. However, other social institutions are also of great value in enabling farmers to negotiate access to obtain resources such as draft power, transport and credit. Such institutions also help farmers protect themselves from risk by the development of social networks through which help can be sought in times of need.
- Data on nutrient balances demonstrate a mixed pattern of accumulation and depletion, depending on plot, farmer and location. Overall, cash-crop land receives the major share of both mineral and organic fertilizers applied. Land sown to lower-value crops, such as coarse grains, shows a consistently negative nutrient balance. However, due to rotation of crops, cereal yields can often benefit from residual fertility stemming from the previous year. Location of plots is also important, with land close to the settlement or cattle pen receiving most nutrient inputs.
- Farmers in all sites have been affected by recent policy changes, such as structural adjustment, devaluation and land tenure reforms, as well as exogenous events such as drought. Such changes have brought about major shifts in returns to different crops, as well as the liberalization of crop marketing. Farmers are clearly responsive to such positive changes, which implies that governments have a range of measures by which to influence farmers' decision making. This range of policy options is discussed in more detail below.

Given this diversity of local contexts and the complex dynamics of soil-fertility change, what is the most appropriate way to identify options by which to support more sustainable soil management by smallholders in Africa's more marginal farming areas? Such options must combine different elements: technical choices, strategies for intervention and a range of policy measures. The remainder of the chapter sets out to explore this question. First, the particular incentives – operating at a range of scales from the household to the village to the national context – for farmers to invest in soil-fertility management are discussed. These factors condition the range of technical choices that farmers make. The following section looks at the variety of ways farmers can and do manage their soil fertility and the implications this has for intervention strategies by governments, donors and others. The success of such strategies are seen to be affected by agroecological conditions, household and community-level institutional arrangements, and national policies in a range of areas. It is these policy themes which are then picked up in the following section, when issues of devaluation and structural adjustment, credit, rural infrastructure, research and extension services, and land and tenure reform and decentralization are discussed. A wide range of policies, therefore, are seen to affect soil-fertility management. But how should initiatives directed towards soil-fertility issues be directed? The final section looks at the options, and suggests a strategy which recognizes the multiple dimensions of soil-fertility management, and a process which establishes a more open learning, adaptive process for the design, monitoring and evaluation of policy measures.

Diversity of Agroecological Setting and Farmer Practice

The conditions faced by farmers in sub-Saharan Africa are remarkably diverse. The research sites were chosen to investigate the significance of such diversity for farmer practice. Thus, the sites selected spanned a long transect in Mali from irrigated Tissana and millet-based Siguiné to M'Péresso in the cotton belt, from highland to lowland farming villages in Wolayta, southern Ethiopia, and from high potential Mangwende to Chivi in the low potential region of Zimbabwe. This diversity across the continent and within the different countries studied is mirrored at village level. The options available to poor farmers are much more constrained than those available to richer farmers who have easier access to labour, land, livestock, credit and cash. This theme of diversity can be taken further to farm level, where the management of soils within the farm varies very considerably between parts of the farm. Typically, certain fields tend to receive far greater concentrations of labour and nutrient inputs, while others are more extensively managed. Thus, in Zimbabwe, homefields close to the settlement receive most attention while outfields have limited applications; in Ethiopia, the *darkoa* plots supporting dense stands of enset receive regular supplies of manure and household waste, while further afield maize crops on the *shoka* plot have to make do with little or no amendments to the soil. Similarly, in land-extensive dryland sites in Mali, the *soforo* infields around the village are often black with dung by the end of the dry season and offer well-fertilized conditions for crops of maize and millet. By contrast, the large, shifting outfields, or *kongoforo*, produce a harvest for four or five years before being abandoned to fallow and occasional grazing. Where cotton has become important, the availability of chemical fertilizer modifies this pattern and enables more permanent cultivation of larger bush fields.

This diversity at different scales has very important implications for how best to support improved farmer management of soil fertility. There are no simple messages regarding appropriate ways to manage Africa's soils. While depletion or 'mining' of nutrients may constitute a problem for certain fields, there are others which are accumulating nutrients. The research has helped identify the locations in which soil-fertility management has become a key issue. Villages such as Siguiné in Mali can still manage a system of fallowing and nutrient transfers from grazing in crop land and thereby maintain grain yields, albeit at low levels. For them, low and erratic rainfall and uncertain prices are at least as much constraints on assuring food security as the fertility of their soils. The sites in Ethiopia demonstrate a relatively efficient system of managing and recycling of biomass and nutrients, although these are tightly constrained by limited access to markets, poor veterinary services and the high cost of mineral fertilizer. In Zimbabwe, the two locations demonstrated marked differences in terms of their productivity and market access. Mangwende is in a relatively high-potential area, with reasonable rainfall although poor soils, and is well connected to markets in Harare and Chitungwiza. By contrast, Chivi is in a semi-arid zone where frequent droughts reduce productive potential. Although there are good road connections to Masvingo to the north and South Africa to the south, there are fewer market opportunities.

The research on differences in soil-fertility management between socioeconomic groups has helped identify households for which soil-nutrient decline constitutes a serious problem. Poorer households in all sites faced particular difficulties in maintaining the productivity of their farmland, due to very limited supplies of livestock dung and poor access to credit and inorganic fertilizer. Such difficulties are a reflection of their limited assets and capacity to mobilize resources more generally. Poor farmers in Dilaba, Mali and Chivi, Zimbabwe were additionally constrained by the disappearance of fallow land and lack of access to credit. This diversity has major implications for design of technical options, extension approaches and policy frameworks for improving soil-fertility management.

Farmers' Concern for Soil-Fertility Management: The Broader Context

As the case studies have shown, the capacity of different farmers to invest in improving soil-fertility management depends on a range of factors which operate at different levels. For the household, these factors include access to labour, livestock, land, capital and cash. In all sites, better-off farmers were much better able to invest in larger-scale use of organic and inorganic sources of nutrients. For example, in some sites, having some means of transport, such as a cart, is also critically important in allowing large quantities of biomass to be moved to and from homestead, *kraal* and crop lands. But there was also great diversity in how such inputs are used, since farmers do not spread them universally across all fields and crops. Instead, nutrients tend to be focused on smaller plots of land where higher-value crops (such as vegetables) are grown. In addition, rotation of land spreads fertility inputs over a series of years. For cotton farmers in southern Mali, nutrient inputs were positive for cotton in the year in which cotton is cultivated, but if account is taken of the subsequent two years of rotation with maize, millet, and sorghum, then over three years there is a net outflow of nutrients. Nutrient losses are much more significant on fields where lesser-value crops are grown and which are not a high priority for farmers. However, even here, farmers often make very effective use of the very limited quantities of nutrients available through careful placing and timing of such inputs in relation to rainfall and crop development. In all sites, farmers were experimenting with very small additions of mineral fertilizer at sowing or weeding time to gain some benefit at limited cost. At the village level, issues include the range of soils available, the overall pressure on farm land and its availability, access to grazing and forage resources, and the importance of labour flows between households, as well as location in relation to markets. At the national level, factors of relevance relate to macro-economic policy, input–output prices, access to credit, institutions and legislation regarding land tenure and its management, approaches to research and extension policy, marketing and infrastructural investment.

Our research approach used a range of methods to discuss the importance of such factors at farm-household, village and national levels. Interviews with farmers regarding family histories and changes in soil-fertility management practices have brought out the combined importance of changes at household level (such as access to labour, livestock assets and off-farm income sources), and broader economic and institutional factors (such as major shifts in prices following devaluation, and land tenure reorganization). This interplay of household, village and macro-level factors helps explain the differences in performance between different farmers at the time of the research. However, it was also clear from the family and village histories that farmers' strategies are dynamic and continually adapting to a range of new problems, as well as the opening up of better opportunities both in agriculture and elsewhere. In some cases, major events such as drought in Zimbabwe have caused significant changes to the farming system due to reduced supplies of manure following heavy cattle losses. In others, a coincidence of good fortune at family level and the development of profitable options for crop production can enable particular farmers to improve their situation greatly. Thus, for example, the growth of horticulture in the Mangwende site in Zimbabwe has been the result of the growth of urban demand for vegetables and fruit in Harare. Those who have access to wetland areas, labour and reliable transport are able to cash in on this new market. Equally, some farmers in the irrigated rice village of Tissana, Mali were able to gain a large allocation of land within the scheme, because they had a large number of family members at the moment of land allocation. Such land has become increasingly valuable with the growth in vegetable gardening and marketing.

At the same time, the research also demonstrates that maintaining and improving the fertility of their soils is only one among a range of objectives which farmers are pursuing. Farmers are faced with many important choices relating to their farm enterprise, other economic activities and domestic commitments. The decision by farmers to invest effort and capital in improving the soils and productivity of their farmland will depend, in part, on pressures to do so, the perception that changes are necessary and the lack of other options. But it will also depend on their confidence that the returns will be worth it. Soil degradation and nutrient losses are unlikely to prompt changes in farmer behaviour until and unless they perceive clear benefits from doing so.

Exploiting soil capital is a rational strategy for farmers to pursue where the nutrients remain to be tapped and where clearing new land for such purposes is cheaper and easier than investing in purchase of inorganic inputs, or in the considerable amount of labour needed to recycle biomass through manuring and composting systems. Such extensive strategies are clearly apparent in Siguiné, Mali. Farmers are likely to moderate such 'soil mining' where they see declining yields and where they depend on this land for future harvests. Cotton farmers in M'Peresso, Mali are starting to engage in much more intensive nutrient management, following similar patterns as those in the more nutrient scarce sites of Ethiopia and Zimbabwe studied here.

Efforts to 'recapitalize Africa's soils' and to replenish soil fertility need to take into account the broad-based nature of the farm household enterprise. This means that farmers have to weigh up the advantages of investing further effort in improved soil management in comparison with the much broader range of decisions they face, such as the gains from allocating labour to migration, more time spent on trading activities and the need to allocate resources for a forthcoming wedding. This finding points to the importance of setting soil-fertility management within a broader livelihoods approach (Carney, 1998; Scoones, 1998), a theme picked up later in this chapter.

Technological Choices

If the ultimate goal of intervention in soil-fertility management is to increase useful outputs for improving livelihoods, there are a variety of routes to do so, each with differing technological choices. Table 19.1 identifies four clusters of technological options. One focuses directly on the soil resource, by attempting to improve

Table 19.1 *Technology choices for managing stocks and flows of nutrients*

Managing stocks	*Managing external flows*		*Managing internal flows*
Increasing nutrient stocks	*Increasing nutrient inputs*	*Decreasing nutrient outputs*	*Increasing nutrient use efficiency*
P – Recapitalization through rock phosphate or other P additions	Inorganic fertilizer	Erosion control	Composting; residue recycling
	Manure/urine N-fixation (legumes)	Reduce leaching (mulching, deep capture through agroforestry, tillage systems)	Water management
N – Organic matter build-up	Fallowing, green manure, agroforestry etc		Crop choice and management
	Biomass import (leaf litter etc)	Reduce volatilization (manure/urine management)	Fertility input combinations Input placement and synchronization

Source: Scoones and Toulmin, 1999

the capital stock, and thereby the service flows derived from it. The other three focus more on the flows themselves, either reducing losses, increasing inputs or improving efficiencies of nutrient use.

An approach aimed at increasing inputs and reducing outputs suggests a set of interventions, ranging from fertilizer application or soil conservation measures, through a range of biological management approaches, involving agroforestry, green manure production, legume use and so on. The details of such technologies are well known, and many combinations have been tested in field settings across Africa.[1] To different degrees, all options are evident in the different case study sites. Depending on the agroecology of the site, the asset base of the farmer and the institutional and policy context, different options have been picked up and used, singly or in combination.

A number of common elements can be found in the current research and extension activities being pursued in each of the countries studied. In most sites, extension recommendations are dominated by inorganic fertilizer recommendations. Where organic amendments are part of the extension package, they often recommend unfeasibly high levels of application rates.[2] In some sites, particularly as a result of NGO and research projects, a wider range of technologies for increasing nutrient inputs have been tested. For example, all sites have had composting pits tried out, alongside a range of agroforestry options. However, in most cases a simple transfer of technical design to a range of farmer settings has resulted in limited uptake. Thus, for example, in the lowland Ethiopian site, the multiple pit composting system recommended by the Ministry of Agriculture was quickly abandoned in favour of a simpler technology. Similarly, the alley farming techniques which had been promoted were also rejected by farmers, in favour of planting trees in homesteads and along field boundaries. In southern Mali, by contrast, considerable effort has been made by researchers and extension workers over recent years to help farmers develop organic fertilizer production through a variety of means, including composting, which provides organic materials for farmers with few or no livestock. In this way, research has aimed to address the obvious differences in assets and constraints faced by poorer and richer households.

Direct investment in the capital stock of a soil through recapitalization is an approach which has recently been widely advocated (Sanchez et al, 1997). In terms of technologies, this may involve the application of rock phosphate to enhance phosphorous stocks and the use of nitrogen-enriched fallows for nitrogen recapitalization. This has seen little application in the case study sites, although rock phosphate options are being explored in both Mali and Zimbabwe. However, the degree to which such additions may act to recapitalize natural capital or act as a cheap supplementary amendment (perhaps in combination with organic sources) is unclear. For most farmers, such technical solutions are not part of their current repertoire. Their means of increasing capital stocks has rather been through the painstaking, labour-intensive process of continuous fertilization and cultivation. This, as the case studies have shown, takes place largely in gardens and homefield sites where the large bulk of organic matter is placed. For other plots, the options for recapitalization are limited due to limited resources, so that farmers can only hope, at best, to maintain crop yield at a fairly low level.

All sites have experienced various attempts at soil erosion control. In many cases a top-down approach to technical design and implementation has resulted in a great deal of resentment. While farmers readily recognize the importance of stemming nutrient losses through erosion control, the imposition of fixed contour bunds or terraces has not been widely welcomed. Thus, for example, in Zimbabwe, the colonial attempts at soil erosion control became a focus for nationalist opposition during the liberation war of the 1970s, and in Ethiopia, after the fall of the Derg, many farmers dug up their terraces and replaced them with more flexibly designed and less land-consuming alternatives. In the cotton zone in Mali, the CMDT in collaboration with researchers have incorporated soil-erosion control as a central part of their support to cotton farmers in Mali Sud (Hijkoop et al, 1991). This has had considerable success in reducing erosion losses and protecting the income streams of cotton farmers.

More sensitive approaches to land husbandry and soil conservation have emerged in the last decade, which draw more explicitly on farmers' own techniques for managing soils. These often combine the management of soil, water and nutrients in combination, rather than isolating soil erosion as the main issue (see examples in Reij et al, 1996). Combining physical with biological conservation measures and changes in tillage practice perhaps offers the most promising route for tailored interventions in this area. For example, in Zimbabwe research on conservation tillage has been combined with more conventional approaches to soil conservation and newer approaches to agroforestry and biomass management on-farm to come up with a variety of technical options.

Improving the efficiency with which nutrients are used is less often considered when choosing among a range of technological options, but is nevertheless vitally important (Nordwijk, 1998). For instance, application efficiency is sensitive to changes in the mix of inputs applied, where they are placed in relation to the plant, and timing of application in relation to moisture availability and plant requirements at different stages of growth (Woomer and Swift, 1994). A decline or improvement in use efficiency may make big differences in useful output, without any change in inputs, outputs or nutrient stock levels, and so can help to offset the effect of a decline in available nutrients and depletion of stocks for a period. For example, work in Zimbabwe has shown that a very limited amount of fertilizer input, perhaps combined with small amounts of manure, if placed in a particular way and at a time which maximizes uptake efficiency, can produce very significant yield responses, possibly far higher than a general application of an input in a blanket manner (Piha, 1993).

This suite of technological options for improving stocks and managing the flows of nutrients can be applied in a variety of ways. Four different intervention strategies can be pursued, either singly or in combination (Scoones and Toulmin, 1999).

1 One-time soil recapitalization strategy, especially of phosphorous using rock phosphate.
2 High external-input strategy, based on the use of inorganic fertilizer packages.
3 Low external-input strategy, based principally on the use of locally available organic resources.
4 An integrated soil-fertility management strategy, making use of a range of high and low external-input technologies in combination.

A variety of conditions make any one or combination of such strategies more likely in any particular setting (Table 19.2). These include agroecological factors (such as soil type or biomass availability/productivity), household level conditions (such as labour or cash availability), and broader policy conditions (relating to prices, markets, credit, infrastructure and extension support).

The diversity of soils, cropping patterns and management practices within a single farm holding and the dynamic nature of soil-fertility and farming-system change sets a challenge for researchers and policy makers. Diversity of strategy at farmer level implies an approach to intervention which is highly localized and involves farmers in identifying, monitoring and evaluating different interventions for improving systems for soil-fertility management. This requires a flexible and responsive policy environment to support processes of technological innovation and investment in soil-fertility management. Table 19.2 indicates that a number of policy areas influence the likelihood of adoption of different options for soil-fertility management. It is to these issues which we now turn.

Impacts of Policy on Farmer Practice

Farmers in all three countries studied have been affected by a range of policy measures which have influenced crop choice, input use and broader livelihood strategies. Table 19.3 summarizes the range of policy interventions and their impact in the study areas. Five broad policy areas were identified in the case study research as having particularly significant impacts on soil-fertility management: structural adjustment (relating particularly to input–output pricing and marketing); credit; rural infrastructure; research and extension services; and land and tenure reform and decentralization. These are discussed in more detail below.

Devaluation and structural adjustment

In each of the three countries, there have been considerable changes in macroeconomic conditions and broader policies, linked most particularly to programmes of structural adjustment which have shifted substantially the terms of trade and incentives faced by farmers. However, the timing and nature of changes wrought

Table 19.2 *Key conditions for four intervention strategies*

Key conditions	*Recapitalization of nutrient stocks (one-time)*	*High external inputs (especially inorganic fertilizers)*	*Low external inputs (especially organic matter management)*	*Mixed strategy: integrated nutrient management*
Soil type and limiting nutrients	Appropriate for P limited soils, less so when N limited.	Any: fertilizer mix can be adapted to particular soil and plant needs	Most effective for N limited soils, through build up of organic matter	Any
Biomass availability	na	na	High	Variable
Labour requirements	High initial input	Low	High	Variable
Financial costs – credit or subsidy requirements	High	High	Low	Variable
Farmers' skill levels required – requirements for extension support	Low	Low	Medium	High
Need for good infrastructural/market links for input supply	High	High	Low	Medium
Potentially negative environmental or health impacts	Yes	Yes	No	Limited
Intervention focus	Input importation; transport; implementation logistics; farmer and area targeting	Soil testing; fertilizer manufacture, blending; demonstration plots; input prices and markets	Appropriate technology development; training	Local experimentation; researcher–farmer participation; skills training; 'field schools'

Table 19.3 *Impacts of policy on soils management in Ethiopia, Mali and Zimbabwe*

	Ethiopia		*Mali*		*Zimbabwe*	
	Policy context	*Policy impacts*	*Policy context*	*Policy impacts*	*Policy context*	*Policy impacts*
Input–output pricing	Liberalization and devaluation from 1991; subsidies on fertilizers removed 1997. Currency devaluation from early 1990s.	Real prices of both inputs and outputs increased, although profitability of inputs use constrained.	Structural adjustment from 1982 onwards, removal of subsidies for fertilizer and other inputs, abolition of credit programmes. Restructuring of CMDT Office du Niger. Devaluation of CFA, 1994.	Liberalization of cereal markets, input prices up, food price increases, loss of access to credit.	Liberalization from 1991, with removal of all subsidies. Regular devaluations of Zimbabwe dollar since 1991.	Prices of inputs and outputs have risen, with price ratios remaining approximately similar. High value crops (e.g. vegetables, some cash crops) have become more profitable.
Marketing	Well-established informal markets; fertilizers sold through regional trading companies and private suppliers from mid-1990s.	Limited growth of private sector marketing, with negative impacts on prices for farmers. Reliance on extension or project supply of inputs through credit programmes.	Abolition of state cereal board, liberalization of cereal markets, including rice. Private input supply outside cotton growing area.	Growth in private trade, cereals and vegetables increased opportunities for farmers. Cotton remains a government monopoly through CMDT.	Effective privatization of marketing boards, and encouragement of private trade.	Growth of private trading has had positive impacts in the higher potential areas, but less so in lower potential sites where profit margins are lower. Here, growth of contract arrangements has occurred.

Table 19.3 *(continued)*

	Ethiopia		*Mali*		*Zimbabwe*	
	Policy context	*Policy impacts*	*Policy context*	*Policy impacts*	*Policy context*	*Policy impacts*
Credit	Range of informal credit options; bank credit limited; agricultural input credit focused on package programme.	Formal credit largely inappropriate for poorer farmers; package programme results in increased debt burden for poorer farmers and in marginal areas.	Formal credit available only to cotton farmers through village associations. No more credit provided by Office du Niger.	Cotton farmers continue to gain credit for input purchase. Rice farmers rely on private sector. Cereal farmers access informal sources, off-farm cash and NGO credit funds.	From early 1980s, limited availability of formal credit.	Credit a major constraint for many farmers.
Rural infrastructure	Poor road infrastructure, but significant investments since 1991.	Improved transport and marketing opportunities for remoter areas.	Gradual extension and upgrading of main road network. Little improvement in feeder roads.	Farmers near main roads face much cheaper transport to markets, many others rely on carts, donkeys, walking.	Since independence in 1980, major investments in rural road building.	Transportation and marketing is now easier, although costs have increased due to fuel price increases caused by devaluation.

Table 19.3 *(continued)*

	Ethiopia		*Mali*		*Zimbabwe*	
	Policy context	*Policy impacts*	*Policy context*	*Policy impacts*	*Policy context*	*Policy impacts*
Research and extension services	Research service undergoing reform, although current focus on limited technical options; extension dominated by package programme.	Much research inappropriate for poorer farmers, with resulting limited impact. Focus of extension service on package programme also excludes many.	Government research on agriculture under reform. Funding cut and shift to greater client orientation. Main focus has been raising yields of cotton and rice, from technical standpoint. Low potential areas receive no systematic attention, though occasional NGO projects.	Considerable impacts from research and extension for rice and cotton. Increasing attention to diversity of farmer strategies and messages. Very limited impacts of research for dryland cereals.	Research and extension switched emphasis to the smallholder sector following independence. However, significant budget cuts and a continued narrow technical focus have limited the ability of government services to respond to farmer needs.	Research has had limited impact on farmer strategies. The impact of a reduction in extension provision is unclear. Emergence of project-funded research and extension activities has had important, but limited, effects in certain areas.

Table 19.3 *(continued)*

	Ethiopia		*Mali*		*Zimbabwe*	
	Policy context	*Policy impacts*	*Policy context*	*Policy impacts*	*Policy context*	*Policy impacts*
Land tenure	Land owned by the state; no changes in formal land tenure regime expected.	Variable perceptions of land tenure security, although from late 1980s growing evidence of land-based investments. Various forms of land exchange, tenancy, share cropping etc persist.	Land taken as national asset post-independence, with free access for all. Current land tenure reforms allocate responsibilities to rural councils, who may attribute powers of management to village-level structures. Putting land to good use the basis for acquiring rights.	Lack of clarity regarding powers to manage and control access, most marked for common property grazing, woodland, unfarmed areas. Fairly secure tenure farmland through customary systems. Relations unclear between communes rurales (CRs) and village-level structures.	All communal lands remain state property, with rights to distribution now held by rural district councils and local traditional authorities, and recently land councils.	De facto land tenure involves a high level of security in communal areas. Recent emergence of an (illegal) land market in some areas, as well as land invasions.

Table 19.3 *(continued)*

	Ethiopia		*Mali*		*Zimbabwe*	
	Policy context	*Policy impacts*	*Policy context*	*Policy impacts*	*Policy context*	*Policy impacts*
Land reform and resettlement	In past forced resettlement and villagization carried out; currently some discussion of further land reorganization.	Uncertainty over future intentions results in insecurity.	Uncertainty regarding rights and roles of CRs and village-level structures.	Future tensions and confusion likely between powers of CRs and customary structures at village level.	Land reform has been a central pillar of post-independence policy, but until 2000–2001 limited progress had been made.	Land reform and resettlement has had limited impact on farmers in most communal areas.
Decentralization	Regionalization a central policy thrust.	Opportunities for tailored regional programmes and policies, although limited capacities and continued influence of national directives undermine options.	Process of preparation over last 5 years, elections held May 1999. Heavy donor pressure, political control and service delivery the main reasons for decentralization.	Too early to judge. Clarity needed regarding CPR management, rights and roles of CRs and village-level structures.	Decentralization to rural district councils has been ongoing since the 1980s. Lower level development committees at village and ward level were established.	Much of the process of decentralization has involved deconcentration, with resulting reductions in services offered at local level. Village and district authorities have relatively little authority and influence.

by such measures have differed considerably between countries, as have some of the impacts. For example, Mali was one of the first countries in Africa to engage in structural adjustment from 1982 onwards, whereas Ethiopia has only recently begun to cut back on fertilizer subsidies. Overall, structural adjustment measures have led to the rising cost and reduced availability of chemical fertilizer, cutbacks in extension services and changes to crop marketing structures. However, while some farmers (such as those engaged in cash cropping, and those who depend on extension advice) have felt the impacts of such changes fairly immediately, others have been less closely affected because of their greater autonomy.

In Zimbabwe, the Economic Structural Adjustment Programme (ESAP) was introduced in 1991, resulting in changes to marketing, provision of services and input–output prices. These have brought about a major shift in use of inputs and choice of crops, leading to diversification and modifications to land use management (Government of Zimbabwe, 1998). The impact of ESAP was particularly harsh since its implementation coincided with the severe drought of 1991–1992, during which a high proportion of livestock died. Hence, for example, farmers in the drier area of Chivi lost 60 per cent of their cattle holdings, drastically cutting the availability of manure for maintenance of soil fertility. As a result, Chivi farmers have greatly reduced capacity to maintain soil fertility and must concentrate the limited amounts available on their most important crops. The liberalization of grain marketing means that farmers are no longer obliged to sell their maize at a fixed price to the Grain Marketing Board, which now just sets a floor price at which it can constitute essential stocks in case of future shortage (FSRU, 1998). As a result, farmers are exposed to potential gains, but also risks associated with the private trading sector. Private traders are now starting to engage in provision of inputs to farmers for particular crops, thereby establishing an alternative input and marketing channel. Contracts with traders are of greater importance in the higher-potential Mangwende for cotton and vegetables, but, even in Chivi, some farmers are now regularly growing peppers and other vegetables for purchase by traders. In general, less grain is now being grown, with farmers resorting to vegetable gardening which has higher returns per hectare (FSRU, 1998). Limited nutrient inputs are focused on gardens in homefields, or those being established along river banks. With fewer livestock available, there has been a return for many to hoe agriculture, and greater attention paid to incorporation of plant matter within ridge and mounding systems.

Zimbabwean farmers' perceptions of the ESAP are mixed, as might be expected, depending on their access to resources and the opportunities they can gain from changes in prices and markets. In Chivi, farmers' perceptions are universally negative:

> Those who are richer get richer, and those who are poor become poorer... ESAP is like AIDS – it kills you slowly, but surely... farmers cannot benefit fully from market liberalization because the markets fix prices at levels which are disappointingly low... (FSRU, 1998, p458)

In Mangwende, there is more of a contrast in view, given the higher level of agricultural potential and marketing opportunities available:

> ESAP is about encouraging people to work hard to build wealth... removal of price controls and competition amongst businesses can be beneficial if it leads to reduced input prices and better producer prices, as is happening with cotton... ESAP means a more difficult life for farmers because input prices are rising faster than producer prices... (ibid)

In Ethiopia, the impacts of structural adjustment on fertilizer prices are only now starting to feed through to farmers, for whom fertilizer prices have risen significantly in real terms (Croppenstedt et al, 1998). For farmers in Wolayta, these changes have rendered even more inaccessible their access to purchased inputs which has been in steady regression since the closure of the WADU project in 1981 and the withdrawal of credit-based fertilizer support. In the last few years, the Ethiopian government has been strongly promoting and extending the fertilizer package developed with the SG-2000 programme. This may provide the possibility of accessing assured supplies of inorganic inputs at reasonable cost for better-off farmers with sufficient land and good market access. However the SG-2000 package raises serious concerns when spread to poorer farmers and drier, risk-prone areas.

In Mali, structural reforms were begun in the mid-1980s and included liberalization of cereal prices and the abolition of fertilizer credit schemes. Many farmers in the dry cereal-producing areas had never had easy access to such inputs since they were not in an area considered a priority for rural development interventions. However, farmers in Dilaba did have the opportunity to tap into project-supported credit and chemical fertilizers during the 1980s. For rice and cotton farmers, structural adjustment and devaluation of the CFA franc have had a much greater impact because of their engagement in market activities.

Devaluation of the CFA franc in 1994 has had a largely positive effect on farmers in Mali. Prior to 1994, cotton farmers were facing stagnant prices and rising input prices. The CMDT had limited processing capacity and had established a quota system to keep a ceiling on cotton production. The devaluation coincided with rising world market prices for cotton, such that very substantial benefits could be gained from expanding area under this crop. With the CMDT investing in new ginning capacity, and a lifting of quotas, the area under cotton has grown from 200,000ha in 1993 to nearly 500,000ha in 1996 (Jeune Afrique, 1998). While input levels in the first year after the devaluation were somewhat depressed, subsequently farmers re-established former practices. Thus, for example, average net returns per hectare of cotton rose by a factor of 3 to 5 over the period 1993–1996 (Giraudy and Niang, 1996). Prices have also risen for cereals, particularly maize, given high levels of demand from the neighbouring Ivory Coast. Not only the larger, better-equipped farmers, but also the poorer small-farm households have been able to take advantage of these opportunities and expand the area cultivated, gaining a substantial increase in income per hectare because of the large hike in cotton prices paid to farmers. In the irrigated rice zone of the Office du Niger, devaluation has also brought about increased demand for domestically produced rice, since imported Thai rice has become more expensive. As a result, farmers have seen a rise in returns averaging 10–35 per cent per hectare, despite an increase in input prices (Breman and Sissoko, 1998). Those farming households with livestock holdings have also done well following devaluation, given rising prices and increased demand from coastal West African states.

Structural adjustment has brought other changes to certain farming areas of Mali, particularly those covered by the CMDT and the Office du Niger. The Malian government has been required to privatize certain functions formerly carried out by these parastatal organizations, such as provision of veterinary services. The rapid withdrawal from veterinary service provision in 1995 led to heavy cattle losses from disease and damaging impacts on work oxen numbers in the CMDT zone. The CMDT has also been forced to become more transparent in terms of its pricing policy, and the share of cotton profits to be received by each of the three parties – farmers, the state and the CMDT. The programme to restructure the Office de Niger has brought changes in the responsibilities and rights of tenant farmers, providing improved security of tenure, and greater freedom over crop choice and where to market crops. Contract farming of certain vegetables (such as tomatoes for canning) is also now starting to develop in the irrigated lands of the Office du Niger, with traders providing access to credit, inputs, markets and technical advice.

Credit

Throughout sub-Saharan Africa, farmers have limited access to formal financial systems through which to gain access to credit and in which they can invest their savings. The establishment of such systems faces serious constraints which include low levels of income, poor infrastructure, high transaction costs and limited collateral with which to hedge against risks of default (de Groote, 1995). As a result, savings at village level are frequently held in the form of livestock, and farmers rely heavily on informal sources of credit from neighbours and family and earnings from migration and off-farm activities for purchase of equipment and farm inputs. In the research sites, systems to gain access to credit have been undergoing change as a result of structural adjustment and other measures.

Across the study sites, only in the CMDT area of southern Mali is such access more or less assured, though even here the CMDT has passed on responsibility for managing the loans to the National Agricultural Development Bank. In all other sites, while projects may occasionally set up and supply credit to a limited area, in most places farmers must rely increasingly on their own resources or on private sector loans, usually associated with cropping under contract to a commercial buyer. Thus, for example, for rice farmers in Mali, credit is no longer supplied by the Office du Niger, and farmers must rely on private sources with which to purchase inputs and equipment. In the southern Ethiopia research sites, most farmers rely on informal networks through which to gain access to loans. Bank credit is in very short supply and dominated by a few suppliers requiring significant collateral arrangements. Agricultural credit is otherwise limited to the extension programme which offers a fixed package of inputs on credit to farmers with strict systems for repayment. Poorer farmers are in particular difficulties as a result, having very limited networks for raising cash while being unable to make effective use of the credit package. As a result, rising levels of default and debt are affecting the poorer and more marginal farmers in the area. In Zimbabwe, formal credit was offered to all communal area farmers on reasonable terms in the 1980s through the Agricultural Finance Corporation. However, default levels, particularly in drought-prone areas such as Chivi, were very high and the facility has been withdrawn. Today, getting access to credit from government or private bank sources is increasingly difficult, in part because of the stringent conditions applied. Informal lending and savings arrangements are therefore the primary way by which farmers raise cash.

Rural infrastructure

Easy access to markets can provide a major spur to farmers to intensify agricultural production and investment in land improvement (Tiffen et al, 1994). Such effects stem from the impact of a broader array of demands for goods and services, and reduced transport costs bringing better margins on input and output prices.

In southern Ethiopia, the challenges set by the mountainous landscape to road building, combined with low levels of investment, have meant that rural infrastructure is poorly developed. However, since 1991, major improvements to the main road through the study area has brought shorter journey times and more assured access throughout the year. This has been particularly important for the lowland study site where, in the past, travel times to the main market town of Soddo were considerable. Today a greater range of motorized transport opportunities exist at much lower costs. Nevertheless, much transport to market continues to be done by foot and donkey, with people often trekking for many hours to reach a market. The profusion of markets, occurring on a daily basis (and sometimes with day, evening and even night markets), is a characteristic of the Ethiopian rural economy. Such markets give traders the opportunity to make small margins by selling and buying in different places. This source of off-farm income is particularly significant for women. With the increasing access, larger market centres such as Soddo have become more important, sometimes displacing smaller, local markets. This has a number of consequences. For those purchasing and selling goods, improved infrastructure has reduced transport costs with the result that both consumers and producers benefit. However, the reduction in trading opportunities in the smaller markets may have impacts on women's livelihood options, as it is often men, with access to cash, who can afford the transport costs to the larger market centres, with the result that trading activities become concentrated among those with capital assets.

In Mali, maintenance and improvement of the principal roads from Bamako to Sikasso, Segou and the north-east of the country takes up the major share of the roads budget, with very little done to improve feeder roads away from the main arteries. In the CMDT zone there is assured transport for the collection of cotton and delivery of inputs. For Tissana and Siguiné, the large market town of Niono is relatively close and provides many opportunities to diversify crops and income sources. Even in areas much further from markets, people often walk very considerable distances to market. But these distances limit the kind of crop which can be grown for sale, since it must withstand the heat and jolting during the journey, as well as increasing the time and costs involved.

In Zimbabwe in the 20 years since independence there have been major investments in road building, including roads within the communal areas, making transport and marketing considerably easier. There has been a resultant growth in bus and lorry traffic in the communal areas, with competition between operators driving prices down, although this effect has been offset to some extent by higher fuel costs stemming from currency devaluation. There are some differences in the level of rural road infrastructure between the study areas, with Mangwende being particularly well served with good connections to Harare and Marondera. Farmers regularly hire transport in groups for the transport of their produce. For vegetables in particular, timely delivery is key in order to gain the highest prices. In Chivi, the road networks have significantly improved in recent years. However, the distance to major market towns is larger than in Mangwende, with Masvingo being the most important. The road to South Africa which runs through Chivi provides important opportunities for trading both agricultural produce and other items. The tourist traffic along the road also provides a ready market for a range of produce, including craft items.

Research and extension services

Research and extension service provision has undergone major changes over the last decade in all three countries. In part this has been due to structural adjustment reforms which have reduced the expenditure levels in government services. But, in addition, there have been some other changes in focus, with a gradual realization of the need to gear research and extension support to the needs of small-scale farmers. In all three countries this has been a slow process, but through interaction with a range of project-based initiatives, both within and outside government, some changes are being seen in the broader national agricultural research and extension strategy in all three countries.

Since the 1970s, agricultural research and extension in Ethiopia has been associated with a technical package approach. A range of programmes have advocated different technical solutions to small-scale farming problems, but with relatively limited impact. While there has been important research, particularly on new varieties, this has had a limited impact on farming livelihoods in areas such as Wolayta. One criticism is that research has been largely focused on cereal crops for the highland areas. This is of clear national importance, but it has resulted in other agricultural production systems – including particularly the enset/root crop and pastoral systems of the south – being largely neglected. However, over the last few years the national research services have been undergoing signifcant reforms. With the formation of the new Ethiopian Agricultural Research Organization, a new and broader mandate for agricultural research has begun to be defined.

In terms of extension outreach, however, the focus remains on a package approach. This has been reinforced by the national adoption of the improved crop-fertilizer-credit package originally promoted by the NGO SG-2000. While there are undoubted benefits of the package under the right conditions, this does not suit everywhere and everyone. In Wolayta the previous experiences of the WADU programme during the 1970s provide an important lesson. When subsidized credit was available and the infrastructural, marketing and other requirements were covered by the project, significant gains were achieved in cereal production. However, this was at the expense of the traditional root-crop system, and when the project withdrew in the early 1980s, cereal yields collapsed and farmers had to return to a focus on their previous mixed strategy of combining enset with root crops and cereals. Not surprisingly, the impact of the government's agricultural extension strategy in the Ethiopia study areas has been mixed, with richer farmers in the higher rainfall areas being able to make good use of the package. However, poorer farmers by and large have not benefited and many, following poor rainfall years, have gone into debt (Carswell et al, 2000). The limitations of the approach, however, are now beginning to be recognized and a strategy for addressing the problems of poorer farmers in more marginal areas is being developed, with an extension of the range of extension packages to such issues as soil and water conservation and livestock management. The agricultural research sector in Mali largely consists of the Institut d'Economie Rurale (IER) which, despite its name, is mainly technical in focus. Agricultural research has paid greatest attention to the problems faced by cotton farmers in the CMDT area and irrigated rice producers in the Office du Niger. Recent structural reforms to the IER have led to cuts in funding and greater reliance on a range of clients, particularly donor agencies requiring short-term research support for their field projects. At the same time, IER has moved towards a regional model, with greater responsibilities allocated to the five regional research centres (of which Niono and Sikasso are part). At the regional level, consultation committees have been set up in the hope of establishing closer communication between researchers and farmer groups in that area. However, it is unclear how effective these have been in influencing the direction and methods followed by researchers. Rice and cotton farmers have thus received the lion's share of research expenditure. In both cases, this seems to have brought considerable improvements in yield when combined with favourable market conditions. Much greater attention is now being paid to differences between farm households in the CMDT region, so that the difficulties faced by small, poor households can also be addressed.

Rainfed cereal areas, by contrast, have not been the object of concerted research and extension work, with provision of technical advice and credit the result of limited-duration programmes such as the Programme National de Vulgarization

Agricole, or the presence of an NGO field project. Despite this neglect, farmers outside the main cash-crop zones have made very considerable changes to their cropping systems – taking up new varieties, adopting ox-drawn ploughs and experimenting with inorganic fertilizer – based on their own capacity to learn, experiment and share lessons. While earlier research focused on the development of technical packages for farmers based on inorganic fertilizer, much greater effort has been made in the CMDT area over the last ten years to promote more sustainable management of soils. This is being done by work on anti-erosion measures combined with better use of organic materials such as crop residues and manure. Private sources of extension advice and input supply are also growing, related to particular crops being cultivated under contract to a commercial buyer. Thus, for example, in the Office du Niger, irrigated tomatoes are being grown in the dry season for a canning factory, with seed, other inputs and advice being supplied to the farmers by the buyer.

In Zimbabwe, government policy towards agricultural research and extension switched from a concentration on the large-scale commercial farming sector to smallholders following independence in 1980. However, this transition has not been easy. The available technologies and the style of research which predominates in the Department of Research and Specialist Services (DRSS) of the Ministry of Agriculture has resulted in a relatively limited uptake of research results in the communal areas. This problem has been compounded by continuing budget cuts, particularly in the period following structural adjustment. This has limited the ability of station-based researchers to get to the field and interact with farmers. Nevertheless a number of project-based initiatives have in recent years started a more farmer-focused approach to agricultural research. The Farming Systems Research Unit (FSRU) in DRSS, for example, has developed a farmer-led participatory research approach in Chivi and Mangwende, with many experiments focused on soil-fertility issues. This has been complemented by more technical research both within DRSS and at the University of Zimbabwe supported by the Rockefeller Foundation-funded SoilFertNet. The result has been the exploration of a range of technologies and management practices which are more in line with farmer demands, and, in some instances, a quite rapid uptake of new practices.

In Zimbabwe, the links between research and extension have been relatively weak, except through more informal contacts at the local level. Agricultural extension, run by the Ministry of Agriculture department Agritex, has been hit by similar budget cuts as research. This has meant a decline in extension coverage over the 1990s, particularly as a result of reduced mobility due to mileage restrictions. In rethinking the role of extension in the country, a number of important lessons have been drawn from past experience. First, the top-down technology driven package approach which has dominated Zimbabwean extension support since the 1930s has been criticized as not really addressing farmer demands. Second, the high costs of broad field-level extension coverage (with the aim of having an extension worker in every ward) have been seen to be unfeasible given government budget limitations. In particular, the training-and-visit approach, originally recommended by the World Bank in the period following independence, has come in for a lot of criticism as being both too technically oriented and too costly. Drawing on a variety of experiments in alternative types of extension approach, particularly emanating from Masvingo Province (Hagmann et al, 1998), Agritex is now exploring more participatory approaches which redefine the role of the extension worker and the linkages between farmers, researchers and the extension system.

Land and tenure reform in the context of decentralization

Land tenure security is often seen as a critical factor in ensuring effective long-term investment in natural resources. A variety of land tenure reform initiatives have been started across the three country case studies. Various forms of land reform and resettlement have also been significant in affecting the distribution of land resources across the study areas. Land and tenure reform is occurring in the context of broader administrative changes associated with programmes of decentralization.

Farmers in Ethiopia have witnessed major upheavals due to land tenure changes and villagization, which have generated continued uncertainty over their landholdings. The land reform policy implemented by the Derg regime during the 1970s resulted in a major reallocation of land to farmers who were previously reliant only on tenancy arrangements with landlords under the feudal system. While this disrupted the strategies of richer landlords, it did provide new land for those previously unable to farm for themselves. However, despite the reforms significant inequalities in landholding persist, with former landlords often repurchasing or contracting land from poorer households. Today a huge range of landholding arrangements exist, including outright ownership, share cropping, contracting and different forms of tenancy. While many of these are notionally illegal, the range of informal institutional arrangements surrounding land are an important aspect of the local situation.

Resettlement policies to less densely populated areas in the lowlands have been important in Ethiopia since the late 1960s. For example, the lowland case study site was established as a settlement scheme in 1971 as part of the WADU integrated rural development project. The allocation of 5ha plots to former tenant farmers provided new opportunities for agricultural livelihoods, although the consequences of moving to a lowland area with different agroecological conditions and high levels of both human and livestock disease incidence caused many problems. During the 1980s, the policy of villagization caused further changes in landholding patterns. Villagization was aimed at rational planning for increased production, combining private and collective farming arrangements. The broader political effect was to increase the state's political and economic control over peasant farmers. Farmers in lowland areas of Wolayta were forced to move into villages and to leave behind the plots of higher-fertility *darkoa* land which they were in the process of enriching. Fortunately, they were to return to their home sites following the fall of the Derg in 1991 and reinvest in their garden areas. Resettlement and land reorganization have not been major features of land policy under the current government, with the land redistribution efforts in the Amhara region in the mid-1990s not being repeated elsewhere. Movement between sites instead tends to be more spontaneous, with families resettling to new areas (particularly in the low-lands) through informal connections with relatives and other contacts.

In Ethiopia there is continued debate at national level concerning further changes to land tenure (Dessalegn, 1994). The government insists that all rural land will remain the property of the state, but that this should not undermine security of land holdings and customary inheritance arrangements. However, given past government policies – particularly of land reform and villagization – many farmers remain sceptical about government intentions and a sense of uncertainty continues (Worku, 1998). Yet despite this, farmers continue to invest in long-term soil-fertility improvement in their garden sites, and the growth in on-farm tree planting in the area suggests that farmers are not thinking only for the short term (Carswell et al, 2000).

Regionalization, involving a form of political and administrative decentralization, has been a central plank of the post-1991 government's policy. While a process of devolving certain powers to the different regions which make up the country has occurred, it is unclear as yet how far this will lead to major changes in agricultural policy, given the continued political and administrative tensions between central government and ministries at the federal level and the new regional administrations, where capacity and political authority often remains weak. This is particularly apparent in the southern region which is made up of a wide range of disparate ethnic groupings (Young, 1996).

In Mali, the ongoing process of decentralization and land tenure reform provides an evolving landscape within which farmers must plan their strategies. Control over land currently being farmed seems relatively secure, with customary rules predominating (Lavigne Delville, 1999), but there is much greater uncertainty over management of collective resources such as grazing, woodlands and water (Joldersma et al, 1996; Hilhorst and Coulibaly, 1998). These common resources provide a variety of important products, including pasture for livestock which transport nutrients from bush to cropland. In addition, it is also not clear how the powers of the newly established rural communes will relate to customary structures at village level. While the tenure reforms (*Code domaniale et fonder*) propose allocating firmer rights to community groups to control access to resources within their territory, this may conflict with the claims that rural communes may wish to assert over resources now under their formal responsibility (IIED, 1999). Where communes see the allocation of rights as an important source of income and patronage, serious difficulties may arise over the prerogatives of village and commune-level structures. Given that the new *Communes Ruraux* were elected in May 1999 and are currently in the process of establishing themselves, it is too early to judge their likely impact. However, it should be remembered that the rationale for decentralization in Mali (and many other countries) has been based far more on service delivery and political considerations, rather than ensuring more effective management of land and natural resources.

In Zimbabwe, debate regarding land and resettlement has been underway since independence in 1980. After an initial flurry of activity in the early 1980s there has been little action on the ground until the last few years (Moyo, 1998). From the late 1990s, the issue gained greater attention from both government and donors, with a new phase of the resettlement programme approved in 1999. During 2000, however, the politics of land reform changed dramatically, as the ruling party and the 'war veterans' began to focus their electoral campaigning on the land issue. A range of land invasions followed, and an attempt by the government to institute a 'fast-track' resettlement policy. The degree to which such resettlement programmes will reduce land pressure in the existing communal areas, however, remains uncertain. Nevertheless a number of studies show that, if the appropriate support is given to new settlers and resettlement takes place in areas where productive agriculture is viable, then the potentials for a resurgence of smallholder agriculture in Zimbabwe are great. In practice, though, the consequences to date for farmers in the Chivi and Mangwende study areas have been minimal. Relatively few have been able to sign up for resettlement programmes, which have been targeted largely at richer farmers with Master Farmer Certificates. Instead, more informal processes of resettlement are occuring with farmers moving, particularly from dryland Chivi, to other parts of the country (notably Gokwe and the Zambezi valley area) where land is more abundant, and, more recently, nearby commercial farms have been invaded and occupied.

Parallel debates centred more on land tenure reform and decentralization are also ongoing. Following growing concerns about land tenure and rural administration issues in the communal areas, a commission of inquiry was established which suggested a range of changes to land administration and tenure issues (Government of Zimbabwe, 1994). The commission recommended that village areas be granted tenure rights on a collective basis, combined with a review of the village and ward committee system which was widely regarded as inadequate. A greater role for 'traditional' leaders and customary arrangements was argued for. However, the implementation of the recommendations has been fragmentary, with particular rural political contexts largely affecting change at the local level. With the political hiatus of the last few years, little progress has been made on the ground. Decentralization to Rural District Councils has also been seen as a route to more effective agricultural and land management in the communal areas, but, again, the capacities of district councils to do much without significant budgets and in the context of joint responsibilities with central line ministries has been very evident.

Policy Options and Strategies

A range of policy measures, therefore, is seen to affect farmer management of soil fertility. However, rarely has soil-fertility management itself been the main target of such policies. Rather, impacts on soil management tend to be the cumulative results of a series of interventions whose focus and interest lie in other fields. As Scherr (1998, p2) notes, 'policy makers typically consider soil quality not as a policy objective in itself, but as an input into achieving other policy objectives'.

The launch of the Soil-Fertility Initiative (SFI) by the World Bank, FAO and other donors was intended to remedy this weakness (World Bank, 1996). One objective of the SFI has been to identify more clearly those policies which are likely to have an impact on soil-fertility management, where overlaps and contradictions currentiy exist. National soil-fertility action plans are intended to promote greater coherence in policy making by bringing together those bodies with responsibilities which are likely to affect soils, and focusing on ways to encourage longer-term investment in improving soil quality. Thus, for example, the steering group for the elaboration of national plan of action to address soil-fertility management in Mali comprises representatives from the Ministries of Planning and Rural Development, as well as from the CMDT, the Office du Niger, the National Environmental Action Plan, the agricultural research sector, the World Bank and the Dutch Embassy.

It is important to examine both the content of policy (statements and instruments) as well as its process (elaboration, implementation and review) and to try and understand differences between what is said, and what actually happens (Keeley and Scoones, 1999; Mayers and Bass, 1999). It is clear that:

> The policy-making process is by no means the rational activity that it is so often held up to be... policy research over recent years suggest that it is actually rather messy, with outcomes occurring as a result of complicated political, social and institutional processes. (Juma and Clark, 1995, pp128–129)

Several points emerge from examining the policy process in the three countries studied. First, policy changes have stemmed largely from the demands of a range of international actors, rather than from internal debate and consultation among stakeholders at national and local levels. In many African countries, agenda-setting tends to be done within a very limited group of people, largely within government, with little or no public consultation, making it much more difficult to introduce alternative views and perspectives. The World Bank, IMF and major donors have also been able to maintain a highly influential role in policy directions because of the high level of indebtedness amongst many sub-Saharan African states, and their consequent dependence on development assistance. Governments remain heavily reliant on, and reactive to, new international initiatives (such as the Convention to Combat Desertification and the SFI), often in the hopes of gaining renewed funding rather than necessarily feeling committed to the objectives of the initiative in question.

Second, the data which drive such policy debates are heavily reliant on a very limited number of documents, which are repeated time and time again. These include the FAO survey of 1990 (Stoorvogel and Smaling, 1990) and research which attempts to put an economic estimate on soil-nutrient losses (Bishop and

Allen, 1989; van der Pol, 1992). Such data provide simplistic messages regarding the significance, diversity and dynamics of soil-nutrient management at farmer level, and also lead to a blinkered view of the means by which to encourage more sustainable agricultural practices generally. The end result is often a set of policy statements which bear only partial relation to what can be seen at farmer level, but which many are unwilling to contest.

Third, the current policy focus on soil-fertility management needs to be understood in the light of the structural adjustment measures undertaken by African countries under IMF and World Bank guidance in the 1980s and 1990s, which reduced substantially farmers' ability to gain access to inorganic nutrients by cutting subsidies and credit programmes. The fact that the World Bank is behind both structural adjustment and the SFI has sent a set of contradictory signals to African governments, who hope that the SFI may provide a vehicle for the reintroduction of such measures.

New directions? Recognizing the multiple dimensions of soil-fertility management

Interventions to address soil-fertility management need to consider five dimensions which frame the range of options available. First, as has been demonstrated throughout this book, the diversity of sites, soils and strategies found within and between African farming systems is very great. Thus, tailoring approaches to suit the opportunities and problems encountered in any particular location is of key importance. Second, there is a considerable level of differentiation between farmers in any one location, which means that no single package of measures will be appropriate for all. Third, as was clear from the discussion above, there is a wide choice of potential actions aimed at achieving better soil-fertility management, from direct technical inputs to broader macro-economic measures, which can be pursued either separately or in combination. This presents decision makers at different levels with a valuable menu of options from which to choose. The fourth dimension concerns the time frame over which such measures might usefully be implemented, given current conditions and other ongoing policy changes with an influence on soil management. Some measures produce rapid impacts, particularly those operating through prices and markets, while others are far slower in bringing about changes such as land tenure reforms, and changes to training of extension officers. The fifth dimension concerns the broader context, and how macro-level decisions might better take into account the need to promote more sustainable patterns of soil management at farm level. Hence the potential role to be played by a national strategy for soil-fertility management which forces an explicit analysis of how current policies in a range of fields affect incentives at farm level.

A sustainable livelihoods approach to policy design

So how can these multiple dimensions of soil-fertility management be combined? As the case study research has shown, an exclusive focus on the technical aspects of soil-fertility management is unlikely to generate effective interventions and appropriate policies. Soil-fertility management is but one part of a broader set of livelihood activities that rural people pursue. Taking a more holistic analysis, then, a sustainable rural livelihoods approach outlines the range of different 'capital' assets which such interventions might address, as discussed in Box 19.1. As can be seen, there are many routes to achieving the goal of improved soils management.

For each of the five forms of 'capital' described in Box 19.1, there will be a range of intervention options to be considered, depending on the assets and livelihood strategies of different groups of people, with men, women, younger people, older people, in-migrants and others requiring different forms of support. Thus, for example, ways of improving natural capital will need to consider how to address the particular constraints of poorer farmers with small fields and poor soils, who also have limited access to cash and labour. Thus, attention might usefully be paid to forms of micro-credit best suited to poorer groups, as well as getting extension staff to focus on the differentiated needs of farmers, instead of targeting the 'average' farm household. By contrast, the options open to better-off farmers in a given site are likely to be much broader and, therefore, prompt a different set of interventions.

Box 19.1 *Rural livelihoods: identifying avenues for intervention for soil-fertility management*

- *Natural capital*, through a range of direct interventions aimed at improving the biophysical status of soils, such as recapitalization, use of chemical inputs and build-up of organic matter, and construction of anti-erosion measures.
- *Financial capital*, by support to credit and savings schemes to facilitate the import of nutrients onto farms and investment in labour, transport, or livestock for their manure.
- *Physical capital*, by building roads and other means of communication to improve access to markets and thus shift relative prices and improve incentives for soil-fertility management.
- *Human capital*, through working with and building on farmers' knowledge and skills, to develop more effective partnerships between farmers, research and extension staff.
- *Social capital*, by improving the organizational capacity of farmers to work together, experiment with alternative technologies, reflect and evaluate options and identify needs from technical service agencies.

Source: Scoones and Toulmin, 1999

The way different social groups gain access to these different forms of 'capital' is dependent on a complex interaction of institutions and organizations operating at different levels. The institutional process which mediates access to such assets is therefore a critical component of any livelihoods analysis. For example, in Ethiopia, depending on social status, religious affiliation and the ability to pay in kind for labour, different people may gain access to labour for soil management and other agricultural activities through a variety of different local institutional forms. Such local institutions may interact with more formal organizational structures of the state or development agencies in various ways. Thus, for example, local, largely informal credit or savings organizations operating among networks of kin, friends or church members may be usefully enhanced by externally supported credit arrangements to improve the ability of members to increase financial capital. It is this interlocking, multilayered nature of informal and formal organizational arrangements which is central to an understanding of how livelihoods are constructed by different people in different settings. Insights into the changing nature of institutional configurations across levels, then, can assist with the sensitive design of appropriate interventions which enhance people's own capacities to manage resources.

Combining different approaches

Much of the current international debate on agriculture in Africa pays particular attention to direct interventions aimed at increasing soil nutrients, through supplementing natural capital by, for example, increasing use of inorganic fertilizer. However, there may be more effective means of achieving the objective of improving livelihood sustainability. Box 19.1 suggests other avenues which should also be considered in identifying a broader spread of options for tailoring to local conditions.

In any particular setting, it is unlikely that a single intervention, by itself, will make a big difference to soil-fertility management and improved livelihoods. For example, in agricultural systems where soil organic matter is in short supply, substantial inputs of N may be needed initially to generate sufficient biomass to contribute to the longer-term objective of improving soil structure and building organic matter content. At the same time, work could be initiated through farmer field schools and experimentation aimed at increasing human and social capital through raising skills, knowledge of more effective biomass management and strengthening partnerships between farmers and extension systems. At the macro-level, debate could be initiated on reforms to research and extension systems, ways of improving access to markets and credit, and strengthening of tenure security.

From the case study sites, a range of combined actions can be identified aimed at improving soil management and livelihood sustainability, which address the particular characteristics of location and farm household, as shown in Box 19.2 below.

From these examples based on the field research, a varied choice of interventions can be identified to support more effective soil-fertility management. Some of these are focused at farm and field level, while others relate to wider policy and macro-level changes. An analysis that cuts across scales – from the micro to the macro – and across intervention areas – from technical to institutional – is essential if the appropriate mix is to be found. As we have seen, however, much of emphasis in the past – and persisting to the present – has focused on technical options derived from a limited view of soil management emanating from soil and agronomic studies. The emphasis on inorganic chemical fertilizers is perhaps the dominant example of such an approach, although it could be argued that the low external input and organic farming perspective suffers from a similar weakness and narrowness of vision.

Any technical options, then, need to be seen in a broader context. This points to the importance of a wider socioeconomic and institutional analysis, asking who gains and who loses from different options? How are different intervention options linked into broader patterns of livelihood change? Which combination of institutional and policy factors operate and interact at different levels, and how do they help direct farmers along more desirable pathways of change?

Strategies for Integrated Soil-fertility Management: Following a Phased Approach

As previous sections have shown, a long-term strategy for integrated soil-fertility management needs to take account of a wide range of factors, from the macro to the micro, and across a huge range of policy areas. Such a strategy needs to consider how to implement such a range of measures over time, and best link local-level practice and national level policy. This would allow for the design of a set of interventions to be implemented, which are tailored to particular settings and able to adapt to changing circumstances.[3] A phased strategy would therefore need to start with a period of participatory planning and assessment, the development of new skills, and be linked to a series of decisions regarding the appropriate scale and vehicle for intervention.

A first step would be an initial *assessment of context and constraints* to identify the biophysical, socioeconomic and institutional characteristics of the district, province or commune where work is planned. In parallel, a macro-level analysis is needed of policies which affect the pattern of incentives for farmers to manage their soils more sustainably, given the range of other opportunities and constraints they face, in the agricultural sector and elsewhere. At farm and community levels, *participatory planning and analysis* enables local people, researchers and extension staff to identify a set of activities which farmers want to try, and to establish methods for joint reflection and evaluation. Experience with participatory extension approaches in combination with farmer field schools provides a variety of practical tools for supporting farmers in the analysis of problems, choice of options to test

Box 19.2 *Identifying options for policy and practice: examples from the field sites*

Mali

In the irrigated rice village of Tissana in Mali, the diversification by farmers into crops other than rice is set to continue. Further growth of the scheme is also underway, with investment in construction of new canals and irrigation works into neighbouring dryland areas. Interventions to improve soil-fertility management within the Office du Niger thus need to include a combination of:

- A shift in research and extension from an exclusive focus on irrigated rice, grown with inorganic fertilizer, towards support for other crops, combining organic and chemical materials to best effect.
- Work with newly settled rice farmers who are less familiar with inputs and credit, water management and marketing, as well as how best to maintain and improve the quality of soil on their plots, combined with attention to areas long under cultivation where soils are suffering from salinization and loss of structure.
- Seeking maximum complementation between livestock and cropping enterprises in and around the Office du Niger. Cattle herds depend on gaining access to dry-season grazing, while at the same time providing manure which is becoming a key component of the farming system.

Ethiopia

In the highland site in southern Ethiopia, livelihood options are increasingly constrained. Limited land areas and the lack of available oxen and cash to invest in increasing agricultural production on the small plots of land means that a flexible strategy involving a range of farm and non-farm activities is essential. The current focus for rural development in this area concentrates on an extension package involving improved seeds and fertilizer linked to a credit arrangement, which is implemented in an inflexible manner. Only the better-off can risk the package and gain the undoubted benefits. By contrast, this option increases vulnerability for poorer farmers, as they have no other sources of income or land to fall back on in case of failure. Alternative options could include:

- A wider set of technical options as part of the package, which involve lower-risk crops and management practices.
- A more flexible form of package so that farmers may take different elements of the package in relation to the condition of their soils, their production objectives, their asset status and risk preferences.
- An alternative form of 'credit for livelihoods' which would allow the allocation of credit to a range of livelihood activities to encourage agricultural improvement in the context of wider livelihood diversification.
- The linking of formal credit (from government and private sources) to informal institutions governing savings and mutual assurance.

Zimbabwe

In Zimbabwe, the increasingly uneconomic option of applying inorganic fertilizer at recommended rates has resulted in declining use, even in higher-potential areas where agronomic responses are relatively good. This has potentially negative impacts on the viability of agriculture in these areas, with consequences for economic growth and food security. Farmers' own experiments with combinations of organic and inorganic amendments have not received much attention from research and are not recognized in standard extension support. A range of options for improving the situation suggest themselves.

- A revision of fertilizer recommendations to take greater account of local agro-ecological setting and socioeconomic circumstance, with a set of graded options with different mixes offered by local traders.
- Support for new fertilizer traders and suppliers to encourage a growth in the market. A variety of public–private partnerships could be explored which might help reduce trading margins, particularly in more remote areas, and so reduce farm-gate costs.
- Different bagging options and more variety in fertilizer mixes, with advice offered by retailers, would allow greater customer choice, and perhaps greater demand, particularly from those requiring relatively small amounts for specific uses.
- More emphasis in research and extension on improving fertilizer-use efficiency through different placement and timing options. Combined with innovative ways of combining inorganic with organic sources, limited supplies of fertility inputs could be made to go further, thus increasing productivity.

out, and strengthening of organizational links to help spread ideas and discussion amongst farmers. At the same time, *an assessment of organizational setting* is needed to identify the current strengths and capacity of different channels through which a combination of interventions might be supported. This will depend on existing structures within the existing governmental, NGO and private sectors, the skills and resources available, and the flexibility and openness of different structures to working with farmers in a more intensive and collegiate manner.

As already discussed, the tailoring of soil-fertility interventions to the diversity and dynamics of particular contexts will need to go beyond a purely technical focus, to embrace a much wider set of options (see Boxes 19.1 and 19.2). The skills needed by research, extension and development agents to take forward the approach outlined above will need to include:

- Economic and social analysis to understand the diverse constraints faced by farmers and the historical dimension to the farming system's development, in order to set the particular issue of soil-fertility management within the broader context of farming livelihoods.

- Participatory planning, analysis and facilitation of farmer-led experimentation, by support to processes of learning and exchange, and major changes in the roles of research and extension staff. Such changes are partly underway in many research and extension structures but require further commitment to ensure their firmer establishment, and the integration of participatory approaches within the way such organizations operate.
- Institutional and organizational analysis to identify structures with which to work and pathways along which the goal of improved soil-fertility management can be achieved. For example, in Mali and Zimbabwe there is a much greater role now being played by the private sector (traders, transporters, shopkeepers) in the provision of inputs and purchase of crops. Organizational analysis needs to assess, for example, how best to build on the energy and flexibility afforded by the local private sector to improve access to inputs and markets.

However, it takes a long time to change the ethos and skills base available to institutions such as government research and extension agencies. Hence, a long-term programme for training and retraining may be required, as well as reliance in the short term on other sources of expertise, such as the NGO community.

Developing a strategy for integrated soil-fertility management will also mean making choices about level and strategy. Trade-offs and synergies must be assessed between the following strategies:

- *A local-level focus*, based on a participatory learning approach which gradually builds capacity at this level through the development of skills, pilot projects to test out methods of working with farmers, training of trainers and methods of spreading experience with possible partners. There may already exist a body of organizations with considerable experience in this field on which to build. Even if lacking within a given country, there may be useful experience in neighbouring countries on whose skills such a locally focused programme could be based. Support to networking amongst the various organizations working on participatory soil-fertility management could be one among several ways of spreading such approaches, through exchange of experience and lesson learning. Attention must also be paid to structures of incentives faced by researchers and extension agents to adopt new methods of work, other changes underway in the agricultural research and NGO worlds, the space for local fora to be established and opportunities for linking debate at local level with higher levels.
- *A centralized approach with a technical focus*, such as distribution of rock phosphate supplies for recapitalization of soils. This would require a well-planned system for organization of delivery, instructions to farmers regarding its use and methods for recouping costs. The newly completed National Strategy for Soil-fertility Management for Burkina Faso provides an example of such a technical focus involving the distribution of substantial volumes of rock phosphate mined in the north of the country to farmers in the centre and

north-west (Government of Burkina Faso, 1999). The cost of this activity, estimated to be 5.9 billion CFA francs (equivalent to US$9.7 million), may well be covered from a range of interested donors who often find it easier to provide a single large payment of funds than a smaller, regular commitment.

- *A macro-policy focus*, which aims to influence policy measures in ways likely to improve the incentives faced by smallholder farmers. Such a macro-level focus requires that farmers be sufficiently well-integrated into economic and policy circuits for changes at macro-level to have an impact at farm level. This is much more assured where farmers are already engaged in cash-crop production and reliant on significant levels of purchased inputs. In such cases, price changes for inputs and outputs can have a major and rapid impact on choice of crop, and the level and type of soil-fertility inputs used. In other areas more distant from markets, pricing policy will have more muted effects. Use of macro-level instruments also assumes a willingness in government policy and donor circles to develop a more coherent approach to addressing soil-fertility management for improved livelihoods. Without such coherence, the incentives faced by farmers are, in practice, merely the net result of decisions made in a number of areas with no explicit account taken of their impact on soil management.

As part of any consideration of phasing external support, it may be appropriate to look at how such approaches may be combined at different points. It may, for instance, be essential to address broader macro-policy issues before embarking on a local-level approach, as without such an enabling context at higher level, local initiatives may fail. Equally, it may be appropriate to aim for a top-down, technical intervention (such as fertilizer supply) to address the immediate consequences of short-term food insecurity and build towards a more long-term integrated and participatory approach over some years.

Future Directions?

The approach outlined above contrasts in some important respects with the current round of environmental strategies and conventions which are in the process of preparation and implementation. These include the UN Convention to Combat Desertification, the Soil-fertility Initiative and National Environment Action Plans. One obvious problem raised by these environmental strategies is the degree of overlap, duplication and waste involved in pursing often similar objectives but through different structures, which actively compete with each other, both at national and international level. A second issue concerns the very high cost of preparing such global strategies in comparison with the funding available to implement what has been agreed. For example, it is reckoned that the cost of negotiating the UN Convention to Combat Desertification must far exceed US$100 million over the period from May 1993 (Toulmin, 1997). It is reasonable to ask whether such sums are justifiable given the end product and the likelihood of the intended beneficiaries gaining anything tangible from the National Action Programmes currently being formulated. But the third, and most important, problem concerns the approach taken by these international plans and strategies. Despite a rhetorical flourish in favour of participation and consultation, and a nod in recognition of diversity, such initiatives continue to be led by international donors, and emphasize the important role of international coordination and facilitation, rather than taking measures to ensure real interest and ownership in the countries concerned.

It is vital to have an agreed consensus regarding the nature of the policy problem being faced, and the system of which it forms part. The 'crisis narrative' expressed in many international statements about the state of African agriculture tells a particular story which is appealing in its simplicity. It suggests that things are bad and getting worse, and something must be done urgently. While this may be good at raising the interest of donors and others, it may result in poorly thought-out and hastily implemented projects which make it difficult for other more considered approaches to be carried out. Such interventions may, in some cases, undermine livelihoods and reduce the potential for sustainability in the long term. Programmes which stress inorganic fertilizer use may, for example, push out a more balanced approach including biomass management which would help assure the longer-term structure and productivity of soils.

An alternative, more cautious way forward is needed. Such an approach does not state that 'there is no soil-fertility problem', but rather that problems are local, specific, differentiated and dynamic and will require mostly local efforts to be addressed effectively. This approach proceeds through a combination of farmer experimentation, monitoring and sequential learning as part of a longer-term participatory process. It is less glamorous than global initiatives and spends aid money less on technical aspects and more on building local skills and reforming institutional and policy processes. Such an approach pays particular attention to the phasing and skills required for pursuing this kind of programme, it acknowledges the very diverse set of conditions and practices found at farm level, and it recognizes that African farmers have been very creative in their ability to adapt and cope with rapid changes to the economic, institutional, technical and political settings in which they find themselves. While such an approach focuses on the local and the particular, it recognizes the importance of the broader macro conditions within which local practices are set.

Those in favour of this approach need to establish a rather different kind of debate at global level which avoids simplification. The narrative for such an approach tells a story of diversity and dynamics and the need to support a set of locally generated processes, pay attention to institutional and policy settings and place soil-fertility management issues in their broader livelihood context. It is hoped that this book can make a contribution to this alternative vision and so help set the debate on how best to support soil management in Africa on a new and more productive path.

Notes

1 It is beyond the scope of this chapter to review these in detail, but many other studies provide useful overviews. For example, Bumb and Baanante (1996) and Larson (1993) on fertilizer use; Lal (1984) on soil conservation; Greenland and Nye (1959) on fallows; Vogel (1994) on tillage; Mugwira and Murwira (1997) on animal manures; Giller and Cadisch (1995) on nitrogen fixation and Jones et al (1997) on legume residue use.

2 For example in Zimbabwe, 10 tons of manure per hectare every three years is the standard recommendation.

3 See Defoer and Budelman (2000) for a set of practical guidelines about how to develop an integrated soil-fertility management approach at farm level over a series of cropping seasons.

Social Visions of Future Sustainable Societies

Patricia Benjamin, Jeanne X. Kasperson, Roger E. Kasperson, Jacque L. Emel and Dianne E. Rocheleau

All manner of social issues receive short shrift in the debates on 'environment and development' and 'managing the global commons'. Family life, community, stratification and individual dignity and fulfilment all suffer from varying degrees of neglect, while international security, nature/society relations, economic alternatives and processes of social change are badly in need of new theories. To the extent that the discussion is couched in terms of sustainability, the emphasis has been on reconciling ecological sustainability (planetary life support) with economic sustainability (continued economic growth), while social sustainability (creation of conditions for community and individual well-being) is generally ignored – or equated with economics, which is almost as bad. Social sustainability, we should note at the outset, does not mean the continuation of existing social structures but, rather, creation and maintenance of the conditions for creativity, empowerment, self-determination and self-actualization.

Research, both past and present, reflects this imbalance. For example, in a 1989 World Future Society publication, most of the items absent from a list of issues deemed important by a panel of 17 prominent American futurists are social in nature (Coates and Jarratt, 1989, pp24–25). Current research shows little change: for example, global environmental change is widely construed as a serious global problem with human causes (ICSU, 1987; IFIAS, 1987; IGES, 1999; ISSC, 1989; Jacobson and Price, 1991), yet the International Human Dimensions Programme has a tiny budget compared with the science-based International Biosphere-Geosphere Programme, a dichotomy largely apparent in the national global change research programmes. In general, little funding is available for collaborative, international, long-term social science research, and the funding allocated to policy work is usually for specific policy problems rather than for understanding more broadly human-induced environmental

Reprinted from Benjamin P, Kasperson J X, Kasperson R E, Emel J L and Rocheleau D E. 2001. Social visions of future sustainable societies. In Kasperson J X and Kasperson R E (eds) *Global Environmental Risk*, Earthscan, London, pp467–507.

change. The assessments by the American Council for the United Nations University (ACUNU) in the Millennium Project (Glenn and Gordon, 1999; *State of the Future*, 1997, 1998, 1999) show important gaps to be filled.

This hesitation to engage social issues is perhaps understandable – ecology and economy alone are complicated enough (Daly, 1999); the social and political aspects, as emphasized throughout this volume, are often regarded as intractable and politically touchy; however, the price of ignoring them is high. Social issues are central to problems of environment and development, and are, in any case, worthy of attention in their own right.

Social concerns are critical to environment and development issues in several ways. First, a number of authors, working on an array of environmental-degradation problems, have argued that these issues are fundamentally social in nature. For example, a 'downward spiral' linking poverty and environment is widely recognized (e.g. Durning, 1989; Kates, 2000; Kates and Haarmann, 1992; Leonard, 1989; Mellor, 1988); Blaikie (1985), Blaikie and Brookfield (1987), and Blaikie et al (1994) argue that land degradation is a social problem, related to a 'simple reproduction squeeze' (e.g. Bernstein, 1979). Hunger can be viewed as a distribution rather than a production problem (e.g. Lappé and Collins, 1978; Lappé et al, 1998), as an entitlement problem (Sen, 1981), or as an outcome of political conflicts (Chen, 1990); a few decades ago, it was viewed as a population-control problem (e.g. Ehrlich, 1968). To the extent that any of these observations are accurate, social as well as economic and environmental factors will determine whether clashes of environment and economy can be resolved.

Second, leaving aside momentarily the thorny problem of implementation, if policy makers do attempt directly to reconcile environment and economy, they still face the task of anticipating or identifying institutions, political structures, value systems and lifestyles that are consistent with the desired or necessary conditions. What kinds of social structures, belief systems, families, activity patterns, geographies and aspirations will be compatible with the environment/economy system they recommend?

It is clear that merely making and attempting to implement policy does not necessarily result in actual social change, particularly given the tendency of the policy makers to take existing social structures and institutions for granted. Any changes in resource use, in the structure of the economy or in nature/society relations must all be implemented through the existing social system and will require major changes in that system. Relatively little is really known, however, about the sources and dynamics of social change, and even less under such conditions as global scale of impacts, rapid change, large populations, complex technologies, diverse and interacting cultures, and responses to subtle and systemic problems with long lag times. It is clear that societal initiatives or responses that work in some cultures do not work in others.

These three concerns – global change as a social phenomenon, identification of social systems compatible with ecological and economic sustainability and the dynamics of social change – all point to the need for an integral social science engagement in any discussions of sustainable futures. Furthermore, it is clear that the talents of the entire spectrum of human knowledge and creativity – including all the social sciences and the humanities – are needed to address these issues. Discussion and reflection on the social implications at all scales of current trajectories and possible alternatives are sorely needed. The two overriding issues of where to go and how to get there, defined in social terms, need concerted and determined attention.

To return to the role of planning in the context of ecological and economic reconciliation, although there is an argument that responsible public policy must try to manage key environmental dimensions, planning alone is not enough. Furthermore, it cannot be done in a social vacuum: neither rational environmental policy nor planned economic growth necessarily guarantees fundamental human rights such as livelihood security, freedom, dignity or opportunity; nor do they result in the maintenance of human values, cultures or communities; nor do they enhance human welfare, particularly for marginal or exploited groups. Securing such values must be a principal motive behind whatever planning does occur, and therefore cannot be the prerogative of current planners. The full plurality and diversity of values that exist in society must be mobilized to inform and guide policy making.

This leads to a second (and much more critical) point – that social goals and considerations are, a priori, pre-eminent. After all, fulfilment of basic needs propels human material interactions with the rest of the planet: the entire economic system is supposed to be motivated by the enhancement of human welfare. And then there are the broader dimensions of individual and community experience to which people attach great importance – values and aspirations; our relations to each other and to nature; the need for meaning and fulfilment; the institutions through which we interrelate; avenues for creative expression; meanings, symbols, belief systems; in short, family, culture, religion, work, play, artefacts.

Even if global economic planners and managers do devise an efficient, sustainable way to reconcile economic growth and ecological limits, what would that world be like and would anyone want to live in it? In addressing the future, it is equally possible to make a desirable, livable world the starting point, and to strive for resource use and economic systems that foster the attainment of that future. Do we eschew such an approach because of an assumption that everyone wants to live like upper-middle-class North Americans or Europeans, but cannot, owing to resource limits and economic problems? If so, this is surely an assumption worth examining. Gandhi's famous statement, reported by Tolba (1987), may be relevant here: when asked if independent India should be like Britain, he asked, 'If it took Britain half the resources of the world to be what it is today, how many worlds would India need?'

It is a question of priorities. Social systems should not be forced to evolve from determinations of optimal capital, material and energy flows; rather, economic and material systems should be designed to support social ideals. Stating the same point differently, one can argue that it is no more 'unrealistic' to expect the economic system to adjust to human needs and ecological limits than it is to expect people to change in order to serve economic imperatives or to expect nature to continue to conform to economic demands.

Not that those are the only options, or even that the global capacity to design and implement ways for reaching solutions is well developed. There is little reason to suppose that change really occurs in this way – by top-down management – no matter what the priorities are. At the very least, this exploration needs to be interactive, so that thinking about the future environment and economy is continually tested against thinking about societal and spiritual aspirations. If the direction and weight of current discussion fail to match real priorities, this should be acknowledged and corrected.

Visions and a History of the Future

If the preceding line of reasoning has merit, the envisioning of alternative futures is an urgent priority. Although 'the concept of alternative futures has become the linchpin of current future thinking' (Coates, 1989, p16), much of modern futurist thought has exhibited a very limited conception of alternative futures.

Modern, formal futurism has a relatively short history. Modernists tend to assume that, until very recently, basic survival was an all-consuming endeavour, leaving little time for idle speculations, and that past societies were relatively unchanging and people expected the future to resemble the present and the past. A sense of human influence over one's own destiny grew from the late Middle Ages onward (Polak, 1961, pp1, 33), however, until the positivists, religious and secular repression kept most Western minds fixed firmly on the past and the present (Adelson, 1989). The rapid technological advances of the industrial revolution, along with social changes brought by capitalism and by the revolutions of the late 18th century, raised obvious questions about the future of society (McHale, 1969), while Darwin and the geologists were expanding the magnitude of conceivable timescales (Alkon, 1987). The idea of constant social and material change has been slowly penetrating popular and official culture since the 1840s. It has influenced American government planning since World War I, as it influenced the Soviet Plans of the 1920s and 1930s (McHale, 1969). Forecasting came of age in World War II in the United States, leading to the development of a formal 'science' of futurism.

In his *The Image of the Future*, Polak (1961) warned depressed, post-war Europe of the danger of living with no mental horizons beyond the present and of the need to envision alternate futures. Despite this broad view, modern futurism concentrated on narrow post-war military and corporate concerns such as strategic planning, R&D and marketing (Coates, 1989; Coates and Jarratt, 1989). Governments and corporations, whose ability to pay and high stakes made them easy clients, became the main constituencies (Adelson, 1989). In response to this narrow base of clients, formal futurism has largely abandoned imagery and social imagination and has embraced the technologies of social forecasting and cross-impact analysis. As Elise Boulding (1983) puts it: 'Polak asked for visions. Futurists give blueprints.' We return to some of these issues below.

Despite its substantial shortcomings, formal futurism points to the importance of envisioning alternative futures. 'Visions' may be defined as stories of possible alternative futures (Anderberg, 1989; Nagpal and Foltz, 1995; Stokke et al, 1991). The process of forming them may be viewed as a purposeful strategic choice, as a tactic for moral suasion, or as an innate propensity of the human psyche.

The first posture is exemplified by Gordon (1989, p26), who states that 'without thinking about the future, we abandon our destinies to chance and the decisions of others'. Simmonds (1989) shares this view, arguing that, in order for institutions to get where they want to go, they must have a sense of where they are going and an ability to institutionalize problem solving. This is, perhaps, the inspiration behind the global modelling efforts of the 1970s (see below) and the various scenario-development and integrated-assessment efforts of the 1980s and 1990s (Morgan and Dowlatabadi, 1996; Rotmans and Dowlatabadi, 1998; Timmerman and Munn, 1997; Toth, 1995). Giddens takes a broader approach, denying that humans are condemned to be swept along by inevitable social forces and calling for the exercise of sociological imagination – being 'conscious of the alternative futures potentially open to us' (Giddens, 1987, p22).

The second position generally appears in the context of empowering a specific social movement or project. Caldwell (1985, 1990), for example, adopts it in reference to environmental politics, arguing that scientific knowledge alone is ineffective in changing behaviour, because it provide[s] no comprehensive view of the future – or a route-map to reach it – that most people find plausible and persuasive. Rather, scientific knowledge must be converted into 'a vision of the possible', to be realized through a programme of action that enlists belief, a popular, political movement with 'a vision of the possible that possesses a quasi-religious quality' (Caldwell, 1985, pp195–196). Similarly, Malone (1988, p289) calls for 'unleash[ing] the creative power of human reason' to develop alternatives to nuclear annihilation and planetary environmental collapse; this may be 'an unrealistic dream … but surely at least a vision – and from Proverbs we know "Where there is no vision, the people perish"'.

The third position is an essentialist one, held by many futurists. The claim is that each person carries around a view of the world, built from everyday observation and interpretation, that is projected into the future (e.g. Stokke et al, 1991). According to Adelson (1989, p28), implicit 'images of futures within which … intentions take shape and make sense' are an inherent part of the human psyche which help form our view of the present and are necessary to purposive action. Therefore, neither individual nor group behaviour, culture nor politics can be entirely understood without understanding those images. A better understanding of human behaviour, and particularly its purposive aspects, entails dealing with the key role that images of futures play in shaping it (Adelson, 1989, p33). These images also have a pragmatic role, since they are essential to the ability of individuals, organizations or communities to compose actions, strategies and policies; to fit them into their context; and to give them meaning (Adelson, 1989, p32).

Similarly, Elise Boulding (1983) argues that, from the individual to the societal level, images about 'the not-yet' are constantly generated. This imagery inspires our intentions as we move toward that which we consider desirable. Innate human creativity allows the imaging of alternatives to the present. Despite repression of these images through social stress and socialization processes (such as education), 'all folk experiment with new ways of seeing and doing. The mental imagery precedes the overt act. If this is normal human activity, then utopia-building, in the broadest sense of the word, is a normal human activity' (Boulding, 1983).

Taken together, these conceptions of social visions – empowering, inspirational/manipulative or universalistic – argue for the necessity and power of visions. Polak, taking a mixed idealist/materialist view of history, claims that such images play an active historical role. He argues that forming images of the future requires an awareness of the future, which makes possible a conscious, voluntary and responsible choice among alternatives. These images are constantly reformulated in a dialectical process between the image itself and the actuality of an unfolding future (Polak, 1961, pp1, 41–42).

At minimum, it is clear that some people see a need for overall social visions to guide action – whether that vision is articulated as an artistic creation, a corporate plan or an ideal to guide policy deliberations. Such an enterprise has often been viewed as socially ambiguous. Modern futurism, although 'more respectable than it used to be' (Gordon, 1989, p21), is tainted by the shady aspects of other futuristic enterprises. Futurism gets a bad name from 'mediums and hallucinogens and yuppie stockbrokers … turn[ing] over tarot cards and pork bellies' (Adelson, 1989, p28).

Serious rejection of the value of envisaging societal futures may be found in other quarters. There are some who, except for relatively narrow endeavours such as military or industrial strategic planning and technology assessment (Coates, 1989), see no need for visions, finding in technological optimism and progress a belief that things are already fine or getting better. Among the scientifically orthodox, any endeavour so explicitly dependent on imagination is automatically suspect. Among others, a distrust of unscientific, non-material and (possibly) elitist idealism has lingered since Marx's day. An emphasis on historical specificity and dynamic process rather than static end point, and a claim that the future is unimaginable because it is impossible for those conditioned by present social conditions to conceive of that which will be produced by human beings not yet born acting under new conditions, have engendered disinterest or suspicion about whether the project of envisioning futures merits human struggle.

Despite these views, it is essential to ponder goals and directions. Creating multiple visions – confronting a diversity of goals, values and structures – allows for ongoing clarification, communication, contestation and critique of alternate futures (Nagpal and Foltz, 1995). It also provides a forum for examining possible ramifications of current decisions, envisioned actions and proposed new pathways.

Broadening the discourse

Incorporating social visions into the discourse about the future would serve the purpose of explicitly introducing a number of ignored or neglected elements into the 'managing the planet' discusssion. In the process, it would also open up that discussion to critique and to much wider participation.

Futurists and their clients have been accused of being motivated by goals of control and manipulation (e.g. Dublin, 1991); however, a number of more benign interests – such as concern for children and grandchildren, seeking information on future impacts in order to guide current actions, simple nosiness or curiosity – may also motivate the desire to know the future. Some of us want to know what life will be like after us, and how our time here affects what follows. For others, a deep spiritual connection with the Earth and its creatures, religious or ethical notions of stewardship, or a strong sense of responsibility for the Earth and its future, inspire concern. Still others harbour a deep respect for what has come before – a sense of history. All of these motives reflect a common desire to know what it would be like to live in various possible futures.

Whereas such issues as population, energy, food, pollution and the like do tell us something about the constraints under which society is organized, they shed little light on the nature of lived human experience. Just as today's statistics on coal mining, methane emissions or capital flows fail to capture the experience of most peoples' lives, future scenarios limited to such factors constrain human inquiry, when we should be seeking to liberate and expand it. Whereas some specialists enter the futures discussion in such topics as material flows, atmospheric gases, capital investment, species richness, energy-conversion technologies, agricultural production or demographic profiles, and their results are a needed part of knowledge, such analyses are intrinsically unable to explore the nature of society and the human condition. How people will live, and how all these phenomena will be translated through societal institutions into factors affecting daily life and human dignity, remains opaque and unexplored. Understanding what some future circumstance might feel like not only provides empathy or human interest but also makes possible a holistic view, a demonstration of interconnections.

Thus, 'dispassionate' social science is not the only, or even the most, valid element in the current discourse. In academic terms, a 'passionate' social science and a stronger voice for the humanities are needed. Finding diverse, rich and textured ways of expressing social visions – through literary or artistic means, for instance – can make the issues accessible to more people and can contribute to emancipatory assessment, humanistic orientation and democratic decision processes. The expansion of discourse into the areas of everyday life, tapping our concerns about our grandchildren and about the impacts of our present lives – and piquing our curiosity – can open the possibility of capturing and mobilizing popular attention to important issues, perhaps even enabling the Habermasian dialogue advocated by O'Riordan and Timmerman in chapter 14 of *Global Environmental Risk* (Earthscan, 2001).

Confronting modellers with issues derived from inquiry outside their bounds of analysis, propelling social choices and social possibilities onto the public agenda, and stimulating explicit thinking about alternative futures can all generate a more powerful knowledge as well as greater awareness of the consequences of present decisions and policies (or of passive acquiescence to them). Public dialogue, conducted through alternate social visions, may also help to clarify the fact that no particular technical, economic or environmental scenario is inevitable; that a particular set of variables or trajectories does not necessarily translate into a specific social scenario; and that futures (and risks) must be negotiated. Choice, not determinism, prevails. Viewed in this way, thinking about the future can have an empowering rather than a discouraging effect, and can form an important part of emancipatory global risk analysis.

We have asserted that social concerns have been inadequately addressed in past research attempts at envisioning the future. The outstanding efforts of this type were the global models generated in the 1970s. To test this assertion, we turn our attention to an examination of the social content of this first generation of global models.

Global Models, Futurism and Social Visions

Looking at global models

A number of comprehensive efforts to predict the planetary future were mounted in the 1970s. Several factors spurred this work. Mounting concern over population, pollution and food supplies was expressed in an awakening environmental movement and in such books as Rachel Carson's *Silent Spring* (Carson, 1962), Paul Ehrlich's *The Population Bomb* (Ehrlich, 1968), Barry Commoner's *The Closing Circle* (Commoner, 1971) and E. F. Schumacher's *Small is Beautiful* (Schumacher, 1973). The use of the image 'spaceship Earth' by Kenneth Boulding (Boulding, 1973) and Buckminster Fuller (Fuller, 1969) acquired new power, owing to photographs of Earth taken from space and the moon. Developing computer technologies made possible the manipulation of large quantities of data about the present in the service of constructing plausible futures.

Multiple global models appeared. Their distinguishing features included a global scale; a methodology based on extrapolation from the present; and a focus on the interactions among population, environment and economy. These models and their constituent features have largely defined the terms of the mainstream global environmental debate up to the current time. The emphasis has been on demography, resources, pollution and capital. Social commentary proliferated in the 1950s and 1960s (e.g. Bell, 1973; Fromm, 1955; Galbraith, 1958; Heilbroner, 1972; Marcuse, 1964; Riesman, 1950; Whyte, 1956), including reports on global futures from the likes of the Commission on the Year 2000 (AAAS, 1965–1967;

Bell, 1969) and the International Peace Research Institute (Jungk and Galtung, 1969), and reports addressing the specific issues taken up by modellers [e.g. MIT's Study of Critical Environmental Problems (SCEP, 1971) and the Ward and Dubos (1972) report for the 1972 UN Conference on the Human Environment in Stockholm] – yet the models, not the rich variety of research, were adopted as the defining voice of global environment and development issues. The discussion that follows centres on the models, partly because a new generation of global models is now being created [e.g. the various efforts at integrated assessment; the PoleStar project of the Stockholm Environment Institute, reported in Raskin et al (1998); and the Hammond (1998) analysis of the 21st-century scenarios].

In the early 1990s, Gordon Goodman, Director of the Stockholm Environment Institute, discussed with members of a Clark University group his plans for PoleStar, an analytic process for systematically exploring alternative futures to inform international efforts for coping with global environmental change. The centrepiece of this process as it has developed is an accounting device – the PoleStar computer-based tool, building upon the first generations of global models – that allows an ongoing exploration of global environmental change. The Clark group argued that a process such as PoleStar should include a component missing from the earlier modelling efforts – an explicit exploration of the social nature of future sustainable societies. Such an inquiry would begin with the desired human conditions and social structures, with processes aimed at fulfilling human development and dignity, and would proceed to elicit diverse social visions from a heterogeneous sample of creative thinkers. The outcomes would have tremendous value in their own right, but the process would also complement modelling of economic and physical phenomena, interacting with them by setting up a dialectic (missing from earlier models) in which diverse social arrangements would drive, be explicitly incorporated in, or be compared with, the models. The process would test not only model feasibility but also the modellers' assumptions and implicit world visions (at least, those aspects of the visions capable of being modelled would be tested, thereby enriching the modelling process).

The Clark group undertook an initial experiment, involving a review of the social content of the first generation of global models. As an aid in comparing the social content of the models, we constructed a set of attributes that (arguably) might be used to characterize a sustainable society. We sought to create a frame of analysis by which very different social visions could be compared (see below). This frame included some components typically treated (e.g. population) as well as some less-obvious attributes (e.g. equity, views of nature). A striking lesson of this process was the difficulty of creating an analytical approach that does not lose the richness of texture and interconnections among attributes or components.

Previous listings of important qualities of social visions include everything from Maslow's hierarchy of needs (Maslow, 1959) to transportation systems, from political change to individual spiritual fulfilment. Such a wide range of factors might help to begin to address questions such as those posed above – what it would be like to live in such a society, and whether anyone would want to do so. For the sake of manageability, this wide sweep of characteristics was pared down to a limited set of variables that could be used to construct a comparative matrix. In the interests of 'getting a handle' on what we viewed as the multidimensional nature of social visions, however, we narrowed these wide-ranging themes to a set of somewhat conventional attributes (cf. Jessen, 1981, pp114–116), as well as several that are less conventional. Finding a balance – between having criteria that structure the analysis without overly structuring it – proved difficult. For the limited purpose of reviewing the global models, however, they proved useful in dealing with complexity.

The models

We examined the reports of six global modelling efforts and one related environmentalist tract in an attempt to extract the social visions, if any, contained therein. The models are the two Club of Rome efforts, *Limits to Growth* (Meadows et al, 1972) and the update, *Mankind at the Turning Point* (Mesarovic and Pestel, 1974); Kahn and colleagues' Hudson Institute rebuttal from the right, *The Next 200 Years* (Kahn et al, 1976); the Latin American rebuttal from the left, the Latin American World Model or LAWM (Bruckmann, 1976; Herrera et al, 1976), also known as the Bariloche model (Gallopin, 2001); Leontief's economic model for the UN (Leontief et al, 1977), and the Carter administration's compilation of US government models in the *Global 2000* report (USCEQ, 1980). The environmentalist report is *Blueprint for Survival* by Edward Goldsmith and the other editors of the *Ecologist* (1972).

None of these models is explicitly social; they examine neither social structure nor the lived experience of people. All focus primarily on the economic and environmental implications of global development (Leontief et al, 1977), on the compatibility of economics and natural resources, and on demography as an input governing economics. The variables used are primarily those for which numerical data were relatively readily available. They all use basically the same variables – population growth, production, income, materials/energy consumption and sometimes pollution. Each model or report was created for a specific and limited purpose.

In no case was the primary purpose of a model the elaboration of a social vision. The Latin American and UN (Leontief et al, 1977) reports make no claim to be anything other than economic models; the input–output structure of the Leontief model treats society as a 'black box'. Other model reports specifically state that they do not address social issues, claiming, for example, to be explicitly 'concerned with biophysical matters, as opposed to social, political, and economic developments' (USCEQ, 1980, pp2, 275), and noting that 'no formal model of social conditions' is offered (Meadows et al, 1972, p174).

Even *Blueprint for Survival*, which claims to offer a vision for a radically different and stable society, offers few specifics beyond a call for decentralization; its main emphasis is on resource conservation and a steady-state economy. Its section on ecological disruption is primarily devoted to denouncing technology, while the discussion of social disruption is limited to northern social pathologies such as crime, drug abuse and suicide. Similarly, the Second Club of Rome model includes 'group' and 'individual' strata in each regional model but the model results are concerned with the usual issues – population, food, energy and income. [Nor does this change in the more optimistic second-generation treatment; see Meadows et al (1992)].

A preliminary examination forces acknowledgement of the non-social nature of these models. The reports are dominated by a concern with material and readily quantifiable issues. Although the models are, in some sense, views of the future, their anchors in current data, extrapolations therefrom, and moral or political judgement about the result leave the reports with the distinct flavour of the present. In so far as they have social concerns, these seem to centre around an exploration of limits or material and economic breaking points, rather than an exploration of the nature and qualities of human institutions, values or experiences. They ask what limits of stress this society can endure and what will make this society collapse; they do not ask about intrinsic cultural and individual qualities, about human experiences or about that which is valued. As such, they provide little or no guidance to the central directions by which people can create dignity, liberation or fulfilment or how these may be possible in different nature–society settings.

Evaluating the Models

As mentioned earlier, we formulated a set of criteria for social visions to characterize the essential features of a social vision and to provide a basis for comparing and evaluating the models. We agreed that the overall social vision created by an author or research group could be characterized in terms of scope, bias, scale, tone and vantage point, among other qualities. Within the vision, major spheres of concern – human/nature relationships, material concerns, social organization and value systems – could then be analysed. The specific variables we selected include the following: view of nature, view of human nature, view of time, valid modes of understanding, view of society and social goals, agent of change, population, equity, relative rights and responsibilities of individual and society, political organization and authority, institutions, economic system and exchange, technology, lifestyle, spatial linkages and security. These categories may be loosely grouped as philosophical assumptions, social organization and material arrangements (see Table 20.1).

Table 20.1 *Attributes of social visions*

Philosophical assumptions

- view of nature
- view of human nature
- view of time
- valid modes of understanding

Social organization

- view of society and social goals
- agent of change
- population
- equity
- relative rights and responsibilities of individuals and society
- political organization and authority
- institutions
- lifestyle
- security

Material arrangements

- economic system and exchange
- technology
- spatial linkages

The social content of the models

The results of analysing the models using this framework are summarized in Table 20.2. Several points should be noted. For many of the categories, 'not addressed' would be the most appropriate notation. If a diligent search of the text revealed even some small mention of the topic, however, it was considered an indicator of the authors' attitude and incorporated into the matrix. As a result, we have in some cases characterized a model on the basis of a brief passage. Mesarovic and Pestel, for example, devote a brief space to their view of nature, waxing eloquent about human survival depending on living in harmony with the web of life. We have repeated these phrases in our characterization, for they express the explicit views of the authors; however, the overall tenor of their report and the model itself treats nature solely as a collection of resources. In other cases, where we found no specific mention in the text but an obvious characterization could be extrapolated from the overall tenor of the text, we have done so. None of the six models, for example, overtly expresses a conception of time, yet all implicitly treat it as linear.

Organizing the attributes into the aforementioned loose categories – philosophical assumptions, social organization and material arrangements (Table 20.1) – permits some general observations. In the sphere of material arrangements, the models are fairly forthcoming, offering moderately detailed visions of economic and technological conditions and at least a general sense of spatial linkages. Philosophical assumptions are, for the most part, not explicitly addressed at all, but implied stances may in many cases be gleaned from the overal tenor of the text,

Table 20.2 *Comparison of social attributes of first-generation global models*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Nature	Resources; waste sink; scarcity	Harmony; web of life; human survival; scarcity	Warehouse; conquer; monitor; manage	System; complexity; stable; self-regulatory; predictable	Resources	Economic factor; resources; waste sink; not limiting	Life support; resources	Garden; Gaia; resources	Harmony; resources
Human nature	Culture; creativity, incentive = improvement; basic good	Basic goods; can change; do right thing	Self-interest; incentive = struggle; satisfaction; test/stimulate; structure/purpose; engineered	Part of nature; adaptation; natural law; community; belonging	Not addressed; solidarity; progress	Not addressed; implied – *Homo economus*	Not addressed; implied – part of nature	Goodness; utilitarian	Rational; do right thing
Time	Mechanical; interval; open future; 70 years	Linear w/ cycles; narrowing options; 50 years	Linear: sequential developing progress; slowing change	Not clear; critical point; industrialism as historical aberration	Linear; history open-ended and depends on human will; process as original	Linear	Linear; future as extrapolation of present; narrowing options	Linear; holistic	Linear
Valid modes of understanding	Rational science; analyse, then manage; science engaged in morals	Holism; science; objective + subjective; science engaged; participation	Rational; engineering; objective; science; morality	Culturally determined; may be many; science serves ecosphere	Analytical; rational; economic models; ideology	Analytical; rational; economic models	Analytical models	Science; interdisciplinary; surprises; linear argument for non-linearity	Rational

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Society and goals	Homogeneous system to be managed; open future; participation; can set limits; leisure; freedom from struggle	Sustainable material and spiritual; cooperation; organism; can adapt	Stages; high morale; dynamism; consensus; smooth function	Stability not expansion; analogue of nature; system; hierarchical; functional	Goals = equity; produce for need not profit; social (not state) control	Development; wealth; employment; NIEO;[c] justice; rationality	Not addressed (explicitly); highly evolved system	Not addressed	Not addressed
Agent of change	Moral resources; values; gradual	Individual or society? Values; internal crisis; 'public figures'; 'political leaders'	Positive images; individual; influence not choice	Economic decentraliza-tion; con-scious restructuring; education in new values	Not addressed; locus = property and production – structural changes	Not addressed; economic restructuring as implied driver	Information; planning; analysis plus political will	Managers; also technologi-cal, institutions, research; having vision	Individuals; having vision
Popu-lation	Out of control; major threat by 2050	Serious problem; 35 years to fix	Rate high but declining; not a problem; economic development will slow growth; colonize space; 7–30 billion	Major threat; wealth will not necessarily slow; ZPG;[d] 3.5 billion maximum; halt immigration	Need to slow; economic development as precondi-tion; focus on basic needs; urbanization	Not a big problem; wealth slows growth; economy can keep up	Major problem; reducing carrying capacity; 10 billion under 'intensive manage-ment'	A problem but not too serious; still time 8–11 billion	Must stabilize at 8 billion

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Equity	Social goals: justice = basic needs	Narrow income gap; we're all connected	Gap to persist; inequity nor mal, healthy, moral	Not addressed; implied goal	Main goal	Main goal	Increased	Not addressed	Need for redistribuon, not growth
Rights and responsi-bilities	Basic needs; produce food; moral resources; behavioural restraint; trade-off of freedoms	Not addressed; share global wealth and resources; change values	All share in market levers of control; individual struggle for meaning; individuals maintain morale	Maintain social economic stability; restrain consumption, reproduction; provide goal structure – prestige	Basic needs; priority = needs; universal rights; work collectively	Basic needs; benefits of development	Not addressed	Not addressed	Individuals responsible to shape society; emphasis on voluntarism
Political organiza-tion and authority	Not addressed; nationstate; define values then choose; participation	Nation state; global cooperation; reduced polarization	Nation state; no world government; reduced competition; manipulative power; elite rule; public lacks expertise; democracy, if 'republican virtues' re-established	Decentralized; local, small scale; participation; peer pressure; only unstable society needs strong authority	International socialism; nationstate; participation	Nation state; internally restructured LDC;[e] North surrender power to South	Not addressed; nation-state	More of the same	Not addressed

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Institutions	Institutions to constrain growth; humans will develop unknown institutions	Not addressed; institutions put information before public for action; institutions for global crisis prevention	Specialized; technocratic; impersonal; decline of family and community; innovation institutionalized; control of serendipity/ synergy; privatization; family, economic exchange superseded	Not addressed; 'Movement for Survival' Coalition	Nationstate; cosmopolitan world organization	Not addressed; institutions to close North–South gap	Institutions for long term; global environmental analysis	Better use of existing ones; formal and informal	Not addressed; emphasis on planning

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Economic system and exchange	No-growth; services; human needs; planning implied; resource efficiency; balance of consumption/population; surplus for arts and leisure	Organic model; cooperation; planning implied; restrained growth in North	Growth for South to catch up; North model as universal; technology, institutional, morale as key; eventual slowing of demand	Steady state; stock not flow resource efficiency; minimal disruption; local control; small scale; correspondence of economic/real costs/values	Scarcity = technopolity; human needs; socialist redistribution; social determination of needs; planning; eventual slowing of growth; growth not answer	Develop under-used resources; NIEO[c] to close North–South gap; self-reliance; pollution abatement	Decelerating growth	More of the same	Steady state; intragenerational welfare; durability; high-tech, high design; resource efficiency; conservation; labour-intensive; generalization
Technology	Not cause or solution; useful technofaith as diversion; shape by social need/priority	Not cause or solution; useful; restrain by social concerns	Good to control nature; main human resource; Faustian bargain	Incompatible with stability; anti-ecological – simplifies complexity; hubris; increases vulnerability; should serve decentralization	Avert scarcity; prevent pollution; social control; progress essential	Narrow North–South gap; expand resource exploitation; pollution abatement	Solution available but politically constrained	Brings environmental changes, good and bad	Decentralized; soft-path renewables

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Lifestyle	Art and leisure; leisure time essential for higher pursuits	Standard of living, not just material; less materialism; conservation ethic; social, moral, organizational, scientific growth	Useless work; hedonism; gaming, art, education, ritual, social interaction; secular with romantic, mystic counter-reaction	Personalized; intimate; self-reliance; pleasure of community; non-materialistic; reintegrated work/home	Not based on consumerism; rich to reduce consumption	Lower Northern consumption; higher Southern consumption	Not addressed	Not addressed	Non-materialistic; simple, frugal; personal/social development; integrate home/work; telecommuting and bicycles; rich/poor convergence
Spatial linkages	Not discussed	Diverse regions; inter-regional cooperation; diversity key to survival, and to moral strength	Homogeneity – 'they' become like 'us'; modernism; links impersonal, business-like; urban/suburban globe; huge economic scale	Decentralized but linked; small scale; diverse rural/urban mix; material self-sufficiency	Autarchy; North–South interconnected; economic complementarity	15 political/economic regions; regional interaction; international trade	Food, energy imports; use distant resources; unaware of environmental impacts	Region-to-globe links; global noosphere	Reversed global interdependencies; local self-reliance; population rural and dispersed; decentralized

Table 20.2 *(continued)*

	Meadows et al (1972)	*Mesarovic and Pestel (1974)*	*Kahn, Brown and Martel (1976)*	*Goldsmith et al (1972)*	*LAWM[a] Herrera et al (1976)*	*Leontief, Carter and Petri (1977)*	*USCEQ[b] (1980)*	*Clark and Munn (1986)*	*Brown (1981)*
Security	Not addressed	Disarmament; without reform, conflict will bring nuclear holocaust; confrontation = dysfunctional	Increased violence due to boredom; weakened Northern defences due to false sense of safety	Internal disintegration; chaos of industrial society; chaos leads to dictators, war; deviant behaviour absent; stable society	Not addressed	Not addressed	Tension; vulnerable people; production system; vulnerability to climate change	Not addressed	No war; conflict and fear = environmental not military; UN peacekeeping

a. LAWM, Latin American World Model.
b. USCEQ, US Council on Environmental Quality.
c. NIEO, New International Economic Order.
d. ZPG, Zero population growth.
e. LDCs, Less-developed countries.

with 'view of human nature' being the most difficult to discern. The treatment of social organization is mixed. Equity, and especially population, are central issues in virtually all of the reports and are addressed in some detail. None of the reports, however, offers a comprehensive or coherent picture of social goals, processes, and relations: the attributes listed in Table 20.2 are a collection of brief and disparate mentions culled from the texts. The same scattershot approach involved in the models applies to politics and institutions, with the difference that these are at least recognized by the modellers as important topics – not that this recognition results in any comprehensive or systematic treatment. Finally, lifestyle and security issues generally receive brief mentions, but are not elaborated.

Further generalizations may be gleaned from a more detailed look at each of the attributes. All of the models treat nature primarily as a bundle of natural resources. None of the reports includes an overt discussion of conceptions of time or notions of legitimate modes of understanding, but implicit in all of them is a linear view of time and a reliance on rational, analytical scientific thought and quantitative data.

The models are fairly evenly split on whether individuals or society as a whole, values, or economic structure drive social change, but none of them explores this issue beyond the level of assertion. The reports also split on the issue of whether population is a problem. All models except those by Kahn et al (1976) and Goldsmith and colleagues (1972) state explicitly that equity is a major social goal, and the latter implies it. The notion of equity adopted is itself limited, focusing on the admittedly pressing issue of inter-generational equity and particularly apparent distributional inequalities among nationstates. On the other hand, the complexity of equity deliberations such as the valued goods to be distributed, the relevant populations used to structure analysis and the philosophical principles by which to define social justice receive scant attention. Those studies that propose means of achieving equity advocate economic growth (Kahn et al, 1976; Bruckmann, 1976; Leontief et al, 1977; Mesarovic and Pestel, 1974) or redistribution (Goldsmith et al, 1972, implied by Bruckmann, 1976; Herrera et al, 1976; Leontief et al, 1977). Most of the models advocate economic growth, although Meadows et al (1972) and Goldsmith et al (1972) oppose it, and Mesarovic and Pestel (1974) call for a different kind. With the exception of Kahn et al (1976) and Bruckmann (1976), all agree that technology is not the solution to environmental and economic problems, with Leontief taking a middle position. It is interesting to note that, except on the issue of equity, the positions taken by Kahn et al (1976) and the advocates of the LAWM model are the most alike: they agree that population growth is not a problem and that resources are not limiting; they advocate economic growth, believe in technological solutions and argue that environmental concerns are secondary to economic ones.

As mentioned above, for those attributes (e.g. philosophical assumptions, social organization) central to a deeper understanding of society, the models take a haphazard approach, implicitly assigning peripheral importance to them. On the question of 'human nature,' for example, all but Kahn et al (1976) – who emphasize struggle and self-interest – imply a belief in the basic goodness of people. Little attention is given to the nature and goals of society or to the structure of the relationship between the individual and political society. Disparate details related to political organization and calls for international cooperation appear in the various reports, but issues of power, authority, conflict and security are generally not addressed at all, or are addressed only very briefly. The same is true for institutions – only Kahn et al (1976) really treat them at all, and their analysis is sketchy. The models make more mention of lifestyle, with many general calls for less materialism and more creative leisure activities, but this is for the most part left to individual decision making and not linked to social and economic structure or to broad social policies. Finally, spatial linkages, if treated at all, are discussed in general terms, such as degree of centralization and homogeneity, or in terms of North–South economic relations, despite the growing evidence of the importance of regional linkages to the global economy and social movements.

Model visions

From these observations (and the details in Table 20.2), it is clear that – even using relatively conservative and conventional categories and giving the modellers the benefit of the doubt by extracting minor details and extrapolating from the tone of the text – the models fail badly to confront social or philosophical issues, much less to probe them in any depth. The modelling approach is based on quantitative analysis using largely linear extrapolations from the present. Its materialistic (as opposed to relational or experiential) bias results in an avowedly utilitarian approach and a largely managerial orientation. The resulting emphasis is on just a few variables – population, resources, pollution levels, technology and economy – with some speculations about their social meaning, in terms of wars, crises, international 'tensions', 'overshoot' or 'collapse.'

Even within the mode of extrapolation from the present, little or no attention is given to current social trends, with the exception of growing global divisions between rich and poor. The major non-demographic social factors for which data exist – such as health, education and settlement pattern – receive minimal attention. Structural considerations related to politics, social norms, the organization of political economy and institutions are only peripherally and sporadically treated; issues such as human rights, cultural diversity, psychological fulfilment, personal relations and freedom are not addressed at all, and neither are environmental or psychological issues, such as the impacts of an increasingly artificial and homogeneous environment (Mumford, 1970, 37 ff) and the social choice of reliability over resilience (Blaikie et al, 1994; Timmerman, 1981).

The first-generation models performed the invaluable services of initiating discussion about possible economic and environmental futures; of taking a global instead of a national perspective; of treating the planet as a single, integrated whole; and of taking a long-term view. As our review demonstrates, however, the approach of these models was inherently limited by the specific rationality and methodology employed. Global problems were approached as essentially economic and resource based, resulting in limited parameters of concern focused largely on material and energy flows. Population, and society in general, were seen as relevant only in so far as they generated (or were affected by) these flows.

Models: the second generation

Efforts to look at the global environment/development picture have become more sophisticated in the 1980s and 1990s. The authors analysed several studies from researchers associated with the International Institute for Applied Systems Analysis (IIASA) and the Worldwatch Institute, applying the same list of attributes used to analyse the models. Table 20.2, above, includes the social visions contained in pieces written in the 1980s by Lester Brown (Brown, 1981; Brown et al, 1990) and by Clark and Munn (1986) on the prospects for a sustainable global future.

The pieces examined demonstrate a more complex view than the models but share a similar focus. Like the modellers, Brown and his Worldwatch colleagues concentrate on population, resources and material/energy flows. Explicit social concerns are limited to an emphasis on lifestyle (presumably in industrialized countries) and the argument that individual behaviour can reduce demand on global resources. Broader social, organizational and structural issues are not addressed. The Clark and Munn piece differs from the first-generation models in its non-linear approach; greater concern with institutions; and the treatment of uncertainty, surprise and discontinuities in the generation of knowledge and its uses. The major concerns, however, remain population and resources, and no distinct social vision is generated.

Although sharing a similar focus with the early models, these more recent efforts attempt to improve on earlier studies by acknowledging the role of uncertainty and surprise in projections and by experimenting with other techniques, such as backcasting and constructing future histories. The importance of surprise was emphasized by the failed projections of some of the early models, and has received significant recent attention (Glantz et al, 1998; Kates and Clark, 1996; Schneider et al, 1998; Toth et al, 1989). Global systems theorists have come to recognize that, for systems near thresholds of change, deterministic analysis no longer works as the system becomes unpredictable and stochastic elements predominate, and inherent indeterminism sets in (see, for example, Gallopin and Raskin, 1998). Research concerned with systems undergoing change must assume the prevalence of discontinuous changes and surprise and be more concerned with uncertainty than predictability. Perrings (1987, p11) distinguishes between 'the probabilistic uncertainty that assumes away our inability to foresee the effects of our actions' and 'uncertainty before ignorance, novelty, and surprise … [arising] from the system's existence in real, historical, irreversible time'. The time in question is, in Georgescu-Roegen's terms, not *time* (the mechanical measurement of an interval) but rather *Time* (the continous succession of moments) (Perrings, 1987, p111). Whereas statistical prediction may have some relevance in *time*, it has none in *Time*. The probabilistic approach assumes the future to be a 'stationary stochastic process' in which a pre-image of the range of possible outcomes exists and various possible futures become rival hypotheses to be tested (Perrings, 1987, p113). But true uncertainty assumes an incomplete set of images of the future and denies that the future is knowable from the past.

The Swedish work on 'surprising futures' (Svedin and Aniansson, 1987) and the IIASA project to develop 'surprise-rich scenarios' (Toth, 1995) are both attempts to address these concerns and to face head-on the major shortcomings of projections. Schneider and Turner (1995) hosted an Aspen seminar on surprises in global environmental change in 1994, aimed at identifying a rich panoply of types of surprise, an endeavour to which Kates and Clark (1996) have also contributed. Despite these helpful advances, the primary concern is still with population, economic growth, technology, energy use and agricultural production. Although much more detailed and sophisticated than earlier modelling efforts, and vigorously developed during the 1990s, the current second generation of models and their scenarios do not include social, cultural and institutional developments and they lack the requisite variety needed to capture possible worlds reflecting the dynamic interplay and different social and cultural groups (Thompson and Rayner, 1998). The models and scenarios still rely heavily on conventional socioeconomic indicators, such as population, energy production, SO_2 and CO_2 emissions, labour force, production capacity, industrial emissions, agricultural production, forest production, water demand – plus a long list of environmental indicators, although more social attributes are being worked into the impacts. Future histories, as in *Beyond Hunger in Africa* (Achebe et al, 1990), are richer and explore a wider range of concerns, including cultural ones. Meanwhile, the *process* for developing integrated assessments also remains disputed; none of the second generation of models is being developed in close conjunction with the decision makers and others who will use them. As a result, they remain politically simplistic and naive and lack the flexibility needed to represent the interests of various interests and social groups over space and time (Rotmans and Dowlatabadi, 1998, p341).

Several promising developments in the current global modelling efforts deserve mention. The 2050 Project undertaken by the World Resources Institute during the 1990s intentionally sought to broaden the social visions involved in alternative future worlds. So, in 1993, project members solicited nominations from a range of colleagues and the World Council of Indigenous Peoples and other NGO leaders to prepare essays envisioning positive futures for their regions or locales. Some 52 'envisionaries' from 34 countries eventually submitted essays in five languages, with developing countries substantially over-represented. The results provide a highly suggestive tapestry of the potential richness of global visions (Nagpal and Foltz, 1995). Hammond (1998) also subsequently examined three scenarios, or worldviews, of the future which he entitled the *market world* – a world of rapid economic growth and technological innovation; a *fortress world*, in which future market failures create a future in which enclaves of wealth and prosperity coexist with widening misery, desperation and conflict; and a *transformed world*, where greater sharing of power and fundamental social change transforms governments and institutions. In a separate effort, Costanza (1999) identifies four 'future histories' – 'Star Trek', a vision of technological optimism, free competition and unlimited resources; 'Mad Max', the technological scepticist nightmare come true, when technology and consumption go bad; 'Big Government', in which protective government policies override the free market; and 'Ecotopia', the low-consumption, sustainability vision.

The PoleStar Project of the Stockholm Environment Institute, referred to above, has also sought a broader framework that includes the conventional IPAT (impacts = population × affluence × technology) drivers of change but also a broader array of social variables (international equity, national equity, welfare, conflict, poverty and political instability), designed to capture the 'interlocking crises' of concern in the Brundtland report (WCED, 1987). PoleStar identifies and analyses three archetypal scenarios of the future – *conventional worlds*, a class of scenarios that assumes that current global trends play out without major discontinuity or surprise in the evolution of institutions, environmental systems, and human values; *barbarization*, scenarios in which fundamental social change occurs but brings great human misery and collapse of civilized norms; and *great transitions*, in which fundamental social transformation occurs but a new and higher stage of human civilization is achieved (Gallopin et al, 1997). Events with the capability to redirect beliefs, behaviours and institutions away from some visions of the future and toward others are posited, as are *sideswipes*, major surprises (e.g. world wars, miracle technologies, pandemics) that greatly alter trends toward particular outcomes (Gallopin and Raskin, 1998; Raskin et al, 1998).

Although these and other efforts of the 1980s and 1990s have come a long way in improving on the earlier models, mostly they are still bound by their focus on a limited set of traditional (if important) variables. It seems fair to conclude that the models have unduly set the terms of social and political debate, defining a sustainable global future largely in terms of population, resource and economic relationships. In other words, the debate and the ongoing work in integrated assessment, with several notable exceptions, remain unduly limited in social content and visions. In this regard, the explicit attention by Robinson in chapter 15 [of *Global Environmental Risk,* Earthscan, 2001] to identify social principles of sustainability is a step in the right direction, as are the use of differing cultural perspectives by the RIVM group in The Netherlands to enrich the underlying assumptions of integrated assessment (Asselt and Rotmans, 1996) and the efforts of the US Interagency Working Group on Sustainable Development Indicators (1998). In envisioning alternative futures, in short, the net needs to be cast to include a larger array of ideologies, religions and cultures but also historians, anthropologists and humanists; of course, some of these will generate dark views of the future (Kaplan, 1994).

The ideology of futurism

Although global models have largely set the stage and defined the terms for current debates on global futures, the formal 'science' of futurism represents the primary institutionalized means for peering into the future. Most futurists have concentrated on the specific interests of their clientele rather than on broad social alternatives or long-term global futures. This professionalized and institutionalized version of the futurological endeavour has attracted substantial criticism of the narrowness of vision.

One critic equates futurism with the institutionalization of prophecy (i.e. forecasting) in an 'attempt by self-appointed experts to rationalize the future' and to impose their own narrow, mechanistic worldview. The prophetic endeavour – and its tendency to reflect the needs of corporate, military and state institutions – trivializes and depersonalizes the future, ignores diversity as too difficult to capture and control, and produces restricted visions that attempt to monopolize the future in the hope that it will resemble the present status quo (Dublin, 1991, p248). Critics early on noted a restriction of the range of alternative futures discussed; an ethnocentric preoccupation with a single society (an idealized, post-industrial North America); as well as tendencies towards technological determinism, mystification and over-quantification; a readiness to apply technical fixes to social problems; and an uncritical acceptance of the status quo (Miles, 1978). The net effect is to empower further the already powerful, to perpetuate an interpretation of the world that serves particular interests and to frame problems so that only certain options are considered (Miles, 1978).

The critics demand a close scrutiny of futurist ideologies – an explicit identification and evaluation of 'what is being sought, by whom, and for what purposes' (Hoos, 1983, p61). Although some futurists have called for extension of the 'futuristic mission farther into the social domain and toward a much larger constituency of stakeholders' (Adelson, 1989, p31), such a 'populist futurism' may also be problematic. Although more participation might result in people having increased control over their own destiny and might produce futures more responsive to wider interests, the means to accomplish this 'may be actually employed as manipulative tools for legitimating the status quo through pseudoparticipation', exchanging fatalism for people's participation in the management of their own exploitation (Miles, 1978, p81).

Forecasting tends to minimize the intrinsic uncertainty of the future by attempting to reduce it to probability. It typically founders on the shoals of institutions and value systems. Although some futurists (e.g. Adelson, 1989; Simmonds, 1989) argue that current organizations no longer seem to work, most futurists work for existing institutions. Adelson (1989, p35) argues that futurists, instead of designing policies for existing organizations, should concentrate on a transition to new institutions, and that efforts to look to the future should be less bureaucratic and institutional and more 'artistic, entrepreneurial, expressive, pragmatic, case-by-case, constructive … visionary'. Adelson (1989, p33) further advocates thinking from the design disciplines, not the sciences – a sentiment echoed by Utopian theorists Manuel and Manuel (1979, p813) in their observation that architecture, not science, provides the most imaginative and authentically Utopian creations of the age. Another futurist points out that, in the chaotic context of changing value systems, forecasting is not very useful: 'All we possess are remnants of previously demolished value systems … inconsistent collections of irreconcilable bits and pieces from the past' (Michael, 1989, p82). Norgaard (1988, p613) describes this as the gradual demise of *Progress* – 'a great carpet under which old beliefs and new contradictions were swept for centuries' – and its likely replacement with the meta-belief, *Sustainability* – the 'clarion of a new age'. Faced with multiple, confusing and uncertain signals, individuals gravitate towards interpretations compatible with their personal worldview – a process that forecasts do not capture.

Some futurists have themselves claimed that the prophetic endeavour, or forecasting, is inherently untenable when applied to society. Forecasting is meant to enhance coherence, but this is impossible in a modern society that is internally fragmented and increasingly incoherent – epistemologically, socially and psychologically (Michael, 1989, p79). For other futurists, a prescriptive or normative futurism offers an alternative to technocratic extrapolations of the status quo. Coates and Jarratt (1989), for example, advocate a prescriptive, ideological and ethical focus, calling for more emphasis on outcomes and less on driving forces. Others dismiss normative futurology as a '*rapture of the future*' which, in the case of social prescription, 'founders on the axiomatic "we"' (Kern, 1987, p216).

Alternative futures

Underlying these criticisms of formal, mechanistic futurism and its traditional constituency is an association of the prophetic, predictive endeavour with goals of manipulation and control (e.g. Dublin, 1991). Such observations should serve not as reasons to disengage from all exploration of future possibilities but rather as warnings. We distinguish between a controlling futurism and the process of creating social visions. We need to eschew blueprints by which some groups control others; rather, we should create means for thinking through the consequences of current actions and for stimulating a sense of open possibilities, of wonder and of power to act.

Although a desire for control serves as a powerful motive for peering into the future, it is not the only alternative: a sense of wonder or of responsibility may also serve as motives. A sense of wonder permits exploration of alternate possibilities while retaining a strong sense of humility toward the future – and the conviction that it will inevitably be more amazing than we can imagine. A sense of responsibility may guide attempts to add the consideration of long-range impacts to present actions, and it may inspire present activities to be conducted in a manner that leads to morally defensible future directions. Envisioning the future and emancipatory risk assessment should be conducted in such a way as to enrich empowerment and a sense of ability to create one's own life.

Alternative motivations are compatible with a diversity of social visions. Multiple visions encourage continuing clarification and communication, and contestation and critique of alternate futures; they also provide a forum for examining the possible ramifications of present proposals, decisions and actions. For multiple visions of alternative futures to flourish, it is necessary to bring diverse perspectives to the table. People operating from different basic assumptions will tend to articulate a multiplicity of social visions; those with alternative views of the present will tend to envision alternative futures. Only by such a multiplicity can there be real choice, or even meaningful debate.

Envisioning Alternative Futures

We have asserted the desirability of an active and broad-based exploration of the widest possible range of imaginable futures. In the context of global environment and development concerns, the envisioning of alternative futures – and exploration of their implications for peoples' lived experience – is an essential component of the hope for a sustainable world. Current processes of envisioning, the content of visions and the political frame for both imaging and images are incapable of creating a rich range of possible futures. Despite attempts at 'backcasting', as reviewed in Robinson and Slocombe (1996) and Mulder and Biesiot (1998), the modern approach to the future is symbolized by a technocratic and economic style and a narrow focus to global models and formal futurism. Social institutions, processes of social change, and human values and aspirations are still rarely at centre stage (but see Robinson et al, 1996a).

The reliance on a single approach to examining possible global futures – modelling – has, in our view, promoted a narrowness and sterility in the imaging process. Complementary or conflicting images – derived from anthropology, novels or paintings, for example – have not yet become relevant to debates on global futures. Despite the goal of some modellers to initiate public debate and stimulate action (Rotmans and Dowlatabadi, 1998), current approaches have too often depicted securing the planetary future as a management challenge properly addressed by experts.

An urgent need exists to enrich this debate by expanding both the content and the form of discussions about global futures. The process of envisioning and debating the future of the planet needs to be democratized and diversified, just as we need emancipatory risk analysis. There is a need to expand the debate into everyday life and to put everyday concerns on the agenda, but also for the discussion itself to become a part of everyday life rather than the exclusive domain of specialists.

In the discussion to follow, we take the modest step of arguing for a broader content in social visions, an expansion that necessitates much wider participation. We argue for the legitimacy of multiple forms of communication, and use the example of science fiction to illustrate the relevance of one non-academic, popular-culture form of vision creation.

Broadening content and form

Enriching the content of future visions and broadening participation may be addressed on several levels. Although the ideal is a wide-ranging democratic discussion – taking place in the world's cities and villages, fields and marketplaces, bars and watering-holes, schools and workplaces, meetings and media outlets – even the confines of policy circles and academia provide ample scope for expansion.

Content: social science

Although a few scholars in the social sciences have come forward to participate in discussions about environment and development or human dimensions of global change, many of the pertinent findings of the social sciences other than economics (e.g. sociology, anthropology, political science, human geography, psychology) are still not incorporated. It is not clear how existing research on cultural identity, social change, political cultures, nature–society relations, international politics or individual development can enrich our understanding of possible futures – a lack which is itself an indictment.

The gap arising from the paucity of attention to prominent social science theory is compounded by the lack of attention to, or visibility of, less-known innovative voices outside the social science mainstream. Those whose views might expand the conventional range of debate, or who question hallowed assumptions, are usually not heard. People doing creative work on a number of theoretical fronts, who may not have published on the subject of planetary futures but who deal with relevant topics, could greatly expand notions of what is possible. For example, critical theorists and oppositional political economists have not chosen, for the most part, to apply their efforts to the economy, institutional structures, politics or social arrangements of alternative futures, nor have they always been effective when choosing to do so. An encouraging counter-example is the flourishing of a vigorous school of ecological economists, who have brought a new, valuable perspective to economic questions. In general, however, theorists outside the confines of conventional disciplines – such as bioregionalists and others concerned with regional and cultural diversity, contemplators of the meaning of place and technology theorists – conduct a largely unacknowledged parallel debate on environment and development.

Beyond the realm of theory, reservoirs of experience have been generated in praxis across a wide spectrum ranging from applied social sciences (such as development, design, architecture, planning, appropriate technology) to social and political activism. A truly enriched debate, one that includes 'passionate' as well as 'dispassionate' social science, would draw from (for example) proponents of bottom-up development, decentralization, local self-reliance; from advocates for the disadvantaged and people confronting poverty; from activists for grassroots environmental action, for community empowerment, for indigenous rights – and any number of other sites of activism. The engagement of activists and the participation of those often left out of the discussion (and especially those vulnerable groups who may disproportionately bear global environmental risks) will broaden the set of questions to be asked. Visions generated from the bottom are sure to challenge the view from the top.

Content: humanities and popular culture

Incorporating social science will bring neglected issues into focus, but the expansion of visions should not stop there. A broader conception should also include the humanities and even popular culture. Expanding the content of social visions to include a wide range of community and individual structures, relations, experiences and consciousnesses should draw on the richness found in literary, artistic, philosophical and spiritual expression. And just as visions drawing on the social sciences may gain from mainstream knowledge as well as the more innovative fringes and from the world of experience or praxis, both formal and informal expressions may contribute.

Can the critiques of postmodernist philosophers and literary deconstructionists be directed toward the positive task of envisioning alternative social futures? Can work by ethicists, philosophers and religious leaders on questions of individual and societal values and aspirations, absent from much of the global-futures discussion, make a contribution? As with social science theory and praxis, there is value in the work of practitioners as well as that of critics in philosophy and the arts; in artists' works and experiences as well as the theories of critics; in the experience of mystics as well as the concepts of theologians. Artists of all kinds can offer a diversity of communicative forms as well as creative new content.

Not only may insights into individual and social meanings be derived from academic work in philosophy, history, literature and the arts; from the work of writers and artists, performers and composers; but it may also come from popular culture, traditional knowledge, folk wisdom, myths and prophecies. Work in rural development, in women's studies and elsewhere has shown the value of folk and women's knowledge (e.g. Richards, 1985; Rocheleau et al, 1996; Shiva, 1994). In the West, popular culture has been recognized as an important source for the expression of contemporary social values (e.g. Browne, 1984).

Broadening the pool of communicative forms

In Western discussions about the planetary future, discourse has generally occurred in a single communicative form – scientific written texts. To the extent that an enriched and expanded envisioning process is desired, multiple forms of expression – including the qualitative, philosophical and artistic – must be encouraged. If the goal of creating holistic as well as reductionist, empathetic as well as objectified visions, is a valid one, then personal as well as impersonal styles of communication and visual, oral or kinetic forms of expression are also legitimate vehicles for conveying these visions. In fact, different forms of expression will be inherent in some of the efforts, suggested above, to broaden the content of visions by including art, popular culture or traditional knowledge. Future visions abound, for example, in American popular and traditional cultures, such as science-fiction novels, short stories, comics and films; Hopi prophecies; post-apocalyptic rock videos; and television shows.

Furthermore, as O'Riordan and Timmerman (chapter 14 *Global Environmental Risk*, Earthscan, 2001) show in their discussion of the paintings of Swedish energy futures, multiple forms of expression may also be used to gainful (and democratic) effect in the social sciences. Local non-governmental organizations (NGOs) and villagers in rural India have been using maps, models and time lines (made from local materials) to theorize the present and to imagine possible local futures (Mascarenhas et al, 1991). The Peace 2010 contest of the *Christian Science Monitor* received 1300 essays, written from the perspective of the year 2010, explaining 'how peace came to the world' (Foell and Nenneman, 1986). Policy exercises like those reported by Achebe et al (1990) use the literary device of alternative histories to construct alternate futures. The essays from diverse 'envisionaries' throughout the world as part of Project 2050 suggest the range of planetary futures that remain to be discovered and articulated (Nagpal and Foltz, 1995). Commentators from the South (e.g. Banuri and Marglin, 1993) see the roots of global environmental destruction in the power and violence inherent in the Western tradition.

Science, Imagination and Story

Within science, the notion of 'objective' rationality, untainted by society, personality or values, tends to be a caricature. Indeed, many scientists have long noted the artificiality of divisions between science and imagination. Popularizers of physics have, for example, pointed out the dissolution of orthodox dualities (matter versus energy, observer versus observed) in the 'new' physics – a physics that explicitly acknowledges that a complete understanding of reality lies beyond the capabilities of rational thought. Statements by Einstein and others on the role played in science by serendipity, inspiration, creativity and a childlike sense of wonder speak to the same point.

Although many scientists embrace qualities such as intuition and imagination, the mechanistic paradigm also survives, zealously protected by orthodox proponents with a tenacity likened by Lynn Margulis (1991, p213) to that of medieval monastic scholars. They reflect the relegation of intuition and imagination to the status of 'other' in much of Western society.

Imagination is an 'absolutely essential human faculty… If you truly eradicated it in a child, he would grow up to be an eggplant' (LeGuin, 1979, pp41–42). This is because of 'the mixture of realism and fantasy that lies at the psychic core of all humans' and the key role played by fantasy 'in the enlivenment and transformation of culture' (Tuan, 1990, p444). In fact, a free but disciplined imagination may 'be the essential method or technique of both art and science' (LeGuin, 1979, p41).

Storytelling is perhaps the most common imaginative expression. According to novelist Ursula LeGuin (1979, p31), stories are integral to human society:

> … [A] person who had never listened to nor read a tale or myth or parable or story, would remain ignorant of his own emotional and spiritual heights and depths, would not know quite fully what is it to be human. For the story … is one of the basic tools invented by the mind of man, for the purpose of gaining understanding. There have been great societies that did not use the wheel, but there have been no societies that did not tell stories.

The writer's exploration of her own imagination taps into Jungian archetypes – the collective unconscious of deep, shared experience that makes possible aesthetic, intuitive and emotional (as well as rational) communication (LeGuin, 1979, p78). This type of communication – accessing multiple dimensions of experience – is precisely what we argue is missing from discussions of the planetary future. Story provides one avenue (among many) for achieving it.

Stories of the future: science fiction

The accessibility and multidimensionality of the story medium serve both to promote a more democratic public discussion and to compensate for the failure of imagination reflected in the sterility of much existing debate about the future. Applied to the future, story adds participant observation to the available methodological repertoire.

A fiction of the future, argues literary scholar Robert Scholes (1975), responds to Sartre's call for literature to be a force for improving the human situation. Such a fiction combines entertainment and intellectual value – wedding idea and story, satisfying both cognitive (content) and speculative (narrative/escapist) needs, and providing suspense with intellectual consequences (Scholes, 1975, p41). Writers of such fiction produce imaginative models of the future, alternative projections that can give us some sense of the consequences of present actions and do so 'with a power which no other form of discourse can hope to equal' (Scholes, 1975, pp17, 74). Scholes asserts that what we need in all areas of life is more sensitive and vigorous feedback. A futuristic imagination 'will inform mankind of the consequences of actions not yet taken. But it must not merely inform, it must make us feel the consequences of those actions, feel them in our hearts and our viscera. [This] imagination must help us to live in the future so that we can indeed continue to live in the future' (Scholes, 1975, p16).

In practice, science fiction is the primary literary genre seeking to accomplish these goals (although Scholes and other critics would deny that all science fiction succeeds). In this visionary role, science fiction has served for decades as a non-academic form of communication in envisioning a wide array of alternate futures. Although there is much to criticize in the genre – including occasional lapses into forecasting – its continued vitality hints at the richness of future visions already existing in society. It provides an excellent example of an existing cultural resource that should be welcomed into policy debates on alternative futures.

Science fiction addresses themes relevant to debates on global futures, such as technology, environment and sociopolitical alternatives. Within the world of popular culture, science fiction has involved large numbers of people in a decades-long public dialogue (between authors and readers/fans) about the shape of possible future societies. This public conversation has utilized the power of the story form – a kind of power that the technical narrative of science lacks. By embracing fantasy, these stories achieve an imaginative range lacking in policy debates: they coax a suspension of disbelief, resulting in a creative expansion of the realm of the possible, and they demand emotional involvement. They are, therefore, able to access the multiple dimensions of personal and social experience and to provide an empathetic and holistic assessment of the possible future being envisioned.

Science fiction is, of course, only one of many potential contributors to an enriched global futures debate, within the realm of story, in a Western popular-culture context.

Conclusions

We have emphasized the social content of future visions and the processes of their creation, calling for the ongoing creation of multiple visions by a broad and diverse array of participants. We have argued in favour of multiple ways of knowing and of diverse expressive forms. We have not, however, addressed the politics of vision creation – how to ensure a diversity of views (diverse in both content and form) and how to achieve wide participation – or the politics of turning vision into action. These are, obviously, enormously problematic. To acknowledge the constraints on the creation of multiple, diverse visions (let alone their implementation) is, nevertheless, not to deny the validity of the visioning enterprise.

Currently, a newly globalized society is undergoing rapid political, economic and cultural shifts. Far from diminishing the validity of, or need for, social visions, chaotic times and conflicting values make them all the more necessary. By stimulating continuous broad-based discourse on alternative futures, the process of creating social visions offers choice and the chance to democratize thinking. The limited visions of alternative futures currently on the table need to be broadened in content to include any and all aspects of human life that various groups of people view as important. Employing multiple forms of expression or modes of discourse will bring not only richer visions but also wider participation and the recognition that envisioning is a dynamic process. In this endeavour, no vision is ever truly completed. There is no possibility of 'One Ultimate Vision'. This is in line with the emancipated and democratic risk analysis which this volume seeks: we believe that it is worthwhile to ponder goals and directions. Visions of the future offer a means to think through the consequences of current actions: there are stimuli for creativity and the sensing of possibilities, and tools for broadening the range and sharpening the terms of debate on possible global futures.
