Ecological knowledge and monitoring among local groups appears to be a key element in the development of many of the practices. The practices are linked to social mechanisms such as flexible user rights and land tenure; adaptations for the generation, accumulation and transmission of ecological knowledge; dynamics of institutions; mechanisms for cultural internalization of traditional practices; and associated worldviews and cultural values (Berkes et al, 2000).

There exist numerous resource management practices among local people that have abandoned the steady-state and linear worldview. For example, there are those that *evoke small-scale disturbances* in ecosystems recognizing that change and also abrupt change is part of development. Such practices trigger small-scale release and create smaller renewal cycles in the local ecosystem and may reduce the impact of large-scale natural disturbances (Holling et al, 1998). Examples include shifting cultivation and fire management for habitat improvement. These practices provide for the regeneration of important resources by creating habitat heterogeneity. Pulse fishing, employed by the James Bay Cree, and pulse grazing, employed by some African pastoralists, represents examples of such disturbance practices (Berkes et al, 2000).

Furthermore, there exist local resource management practices that may be important for *dealing with abrupt change* and disturbance events. Polyculture of

Samoa represents an example of such a practice. A minor food crop, yams, became the most important food for an extended period of time following a large-scale cyclone. Polyculture and 'multiple-disturbance tolerant' species among the char-dwellers in Bangladesh serve the same function by reducing the potential impacts of flooding or droughts (Colding et al, 2003). Diversification of livestock species among many pastoral groups in the African Sahel may reduce the effects of various disturbance regimes such as disease outbreaks and droughts.

Locally protected habitats, such as sacred groves, buffer zone areas and range reserves, may be important for the *reorganization* of ecosystems following disturbance events. Such areas may provide dispersal and migration of animals and plants into disturbed ecosystems. Even taboos imposed on populations of common species may have critical functions in the reorganization phase – especially those imposed on mobile link species (Elmqvist et al, 2001; Lundberg and Moberg, 2003; Bodin et al, 2006).

These are examples of practices common in traditional societies and local communities and that help insure the communities against uncertainty in resource flows and make people adaptive to change (Folke et al, 1998a, 2006)

Social taboos and ecosystem services

Successful resource management systems require flexible social mechanisms for continual adjustments to environmental dynamics. Thus, institutional structures (rules and norms in use) are needed to take environmental variability and ecological feedbacks into account and provide capacity for management to respond to such dynamics. We have analysed social taboos in this context, defining a taboo as a prohibition imposed by social custom or as a protective measure. Such institutions are based on cultural norms that are not governed by government for either promulgation or enforcement. In Colding and Folke (2001) social taboos were grouped into six major categories in relation to their resource and ecosystem management functions (Table 7.2). The last two categories of Table 7.2 can be referred

Table 7.2 *Resource and habitat taboos (RHTs) and their nature conservation and resource management functions*

Category	*Function*
Segment taboos	Regulate resource withdrawal
Temporal taboos	Regulate access to resources in time
Method taboos	Regulate methods of withdrawal
Life history taboos	Regulate withdrawal of vulnerable life history stages of species
Specific-species taboos	Total protection to species in time and space
Habitat taboos	Restrict access and use of resources in time and space

Source: Colding and Folke, 2001

to as *non-use taboos*, because they do not allow for human use of biological resources. The other four categories may be referred to as *use-taboos* since the taboos permit restrictive use of resources (Colding and Folke, 2001).

Segment taboos apply when a cultural group bans the utilization of particular species for specific time periods for human individuals of a particular age, sex or social status. Thus, certain segments of a human population may be temporarily proscribed from the gathering and/or consumption of species. This group of taboos exists in a number of traditional societies in e.g. Africa and South America.

Temporal taboos may be imposed *sporadically*, *daily* or on a *weekly* to *seasonal* basis. Cases recorded in the literature derive e.g. from Oceania and India. Such taboos are imposed on both aquatic and terrestrial resources. In an ecological context, they function to reduce harvesting pressure on particular subsistence resources and are closely related to the dynamic change of resource stocks.

Method taboos are imposed on certain gear types and extraction methods that may easily reduce or deplete the stock of a resource. Method taboos are common in South-East Asia and are often fishing-related.

Life history taboos apply when a cultural group bans the use of certain vulnerable stages of a species' life history based on its age, size, sex or reproductive status. Such taboos may be imposed on reproducing and nesting species, and species particularly susceptible to over harvesting, such as slow moving, or sessile, marine species. Examples of such taboos derive mainly from India and Oceania.

Specific-species taboos prohibit any use of particular species and their populations. The reasons for the existence of specific-species taboos vary, ranging from beliefs in species being toxic, serving as religious symbols, representing reincarnated humans, and species being avoided due to their behavioural and physical appearance.

Habitat taboos are often imposed on terrestrial habitats, river stretches, ponds and coastal reefs. Examples of such 'socially fenced' ecosystem types (Colding et al, 2003) include 'sacred groves' of India and Africa, 'spirit sanctuaries' of South America, *waahi tapu* and *ahupua'a* in the South Pacific and *hima* of Saudi Arabia. Habitat taboos provide for the protection of a number of ecological services on which a local community may depend. These services include the maintenance of biodiversity, regulation of local hydrological cycles, prevention of soil erosion, pollination of crops, preservation of locally adapted crop varieties, habitat for threatened species and predators on noxious insect and pest species of crops, and areas serving as wind and fire brakes.

An example from southern Madagascar (Bodin et al, 2006) illustrates the significance of recognizing culturally protected and managed areas (Nabhan, 1997) in the generation of ecosystem services, like allotment areas or golf courses in the urban context (Colding et al, 2006). In Madagascar the landscape is heavily fragmented, except for small forest patches that hold an abundance of rare species serving as refuges. Analyses of movements of animals illustrate that the landscape due to the small patches is fairly well connected despite the fragmentation and that the forest patches support, e.g. pollination of staple crops in local livelihoods

(Bodin et al, 2006). A national government or an international conservation NGO may conclude that to conserve biodiversity (the rare species) and ecosystem services of the landscapes these forest patches need to be urgently protected from human use and abuse and transformed into no-take areas through legal protection or governmental intervention. But a social-ecological inventory would reveal that they are in fact already protected by a social taboo system of sacred forests (Schultz et al, in press). As a matter of fact, it is such systems that have sustained the biota and ecosystems services of the landscape. Implementing top down policies may disrupt such socially and culturally enforced systems that sustain ecosystem services.

Hence, lack of policy recognition of the social and cultural dimension at local scales of ecosystem management may degrade landscapes further. However, with the information in mind of the significance of the sacred forests and the social taboos, the NGO and the national government could help secure such management institutions, for example, through what Ostrom and Schlager (1996) refer to as umbrella organizations or Alcorn and Toledo (1998) as tenural shells. This becomes increasingly significant in the face of large-scale economic drivers of change or incorporations into global cultures and value systems.

When people comply with self-enforced norms, economic transaction costs may be low relative to formal enforcement measures. During such conditions institutions, like social taboos, may provide for (1) low monitoring costs, (2) low enforcement costs, and in many cases (3) low sanctioning costs (Colding and Folke, 2001). Incentives should be created that strengthen social networks of steward groups for ecosystem management in multi-level governance systems (Folke et al, 2005). It is time to move conservation beyond confrontation to multi-level collaboration (Wondolleck and Yaffe, 2000; Folke, 2006a) and recognize that ecosystem management is to a large extent people's management (Berkes, 2004).

Social networks, ecosystem management and bridging organizations

Ecosystem management is an information-intensive endeavour and requires knowledge of complex social-ecological interactions in order to monitor, interpret, and respond to ecosystem feedback at multiple scales (Imperial, 1999a, 1999b; Folke et al, 2003). We have earlier argued that it is difficult if not impossible for one or a few people to possess the range of knowledge needed for ecosystem management (Olsson et al, 2004a). Instead, knowledge for dealing with social-ecological systems dynamics is dispersed among individuals and organizations in society and requires social networks that span multiple levels in order to draw on dispersed sources of information (Olsson et al, 2006).

In this sense, knowledge of ecosystem dynamics resides in networks. A challenge is to identify mechanisms for organizing relations between relatively autonomous, but interdependent actors (Kersbergen and Waarden, 2004) and avoid fragmented and sectoral approaches to the ecosystem management. Several studies have looked at the role of social networks in inter-organizational collaboration and collective action in relation to natural resource management (e.g. Agranoff and McGuire, 1999, 2001; Mandell, 1999; Carlsson, 2000; Mandell and Steelman, 2003; Imperial, 2005). A challenge is to identify social mechanisms and enabling institutional arrangements that can mobilize knowledge at critical times.

There is a need to increase the understanding of the role of networks in adaptive governance of social-ecological systems and mechanisms for facilitating cross-scale interactions, dealing with uncertainty and change, and enhancing ecosystem management (Bodin and Norberg, 2005; Janssen et al, 2006). Westley (2002) argues that the capacity to deal with the interactive dynamics of social and ecological systems requires networks of interacting individuals and organizations at different levels to create the right links, at the right time, around the right issues.

The Ecomuseum of the Kristianstads Vattenrike is an example of an organization that creates a bridge between local actors and communities with other organizational levels (Olsson et al, 2004b). *Bridging organizations* increase the potential to redirect external forces into opportunities, serve as catalysts and facilitators between different levels of governance and bring in resources, knowledge and other incentives for ecosystem management (Folke et al, 2005). A bridging organization like the Ecomuseum Kristianstads Vattenrike provides an arena for trust-building, sense-making, learning, vertical and horizontal collaboration and conflict resolution (Hahn et al, 2006). It uses networks of local steward groups to mobilize knowledge and social memory, which in turn help deal with uncertainty and shape change (Folke et al, 2003, 2005). The different networks and the numerous linkages that can be activated when needed contribute to the robustness of the social-ecological system and therefore are sources of social-ecological resilience. They constitute the social memory (in the sense of Macintosh, 2000) that can be mobilized at critical times and increase response options to deal with uncertainty and change.

The adaptive co-management and the adhocracy in Kristianstads Vattenrike rely on sleeping links that can be activated when there is a conflict or crisis and the Ecomuseum helps to mobilize experience and social memory for dealing with change (Hahn et al, 2006). Thus, bridging organizations can play a crucial role in the dynamic relationship between key individuals, social memory and resilience. Such structures of social capital need to be recognized and nurtured in conservation and ecosystem management efforts.

Leadership and actor groups

A key mechanism behind adaptive co-management is leadership which can come in different forms. For example, key individuals can provide visions of ecosystem management and sustainable development that frame self-organizing processes (Agranoff and McGuire, 2001; Westley, 2002). Key stewards are important in establishing functional links within and between organizational levels and therefore facilitating the flow of information and knowledge from multiple sources to be applied in the local context of ecosystem management. Social networks often emerge as self-organizing processes (i.e. not implemented by external pressure) involving key persons who share some common interests although they represent different stakeholder groups (McCay, 2002). Leadership has been showed to be of great significance for public network management. Network leadership and guidance is very different from the command and control of hierarchical management (Agranoff and McGuire, 2001). It requires steering for the network to hold together (Bardach, 1998) and a balancing of social forces and interests that enables self-organization (Kooiman, 1993).

However, social-ecological systems that rely on one or a few key stewards might be vulnerable to change. This is exemplified by Peterson (2002) who describes the management of the long-leaf pine forest in Florida and how the desirable state or the stability domain of the forest is maintained by fire as a main structuring variable. Fire frequency has decreased in the area and long-leaf pine forest ecosystems therefore risk entering into other less desirable ecosystem states. The forest is within a military base and an air force general has been a key steward for maintaining the forest through active burning. When the general left his position, a new general who did not share the interests and convictions of his predecessor replaced him. However, some of the personnel who had taken an active part in ecosystem management had developed knowledge and affection for the long-leaf pine forests. They also used a scientist's model of forest dynamics to successfully convince the new general of the importance of fire management for maintaining the desirable stability domain of a long-leaf pine forest ecosystem. This example shows how structures and processes such as social networks can provide a social memory of ecosystem management that sustains adaptive capacity in times of change.

The strength of networks depends on the ability of the key persons to exchange information with other stakeholders, identify common interests and gather support for such interests (e.g. ecosystem management) within their own organization or stakeholder group. Bardach (1998) describes how leaders play different roles in systems of strategic interaction which include eliciting common goals, creates an atmosphere of trust, brokers organizational and individual contributions, and deploys energies in accord with some strategic plan. Organizations that do not appear to have much in common may develop crucial links thanks to these key persons who form the nodes of different, loosely connected, networks. In his seminal paper, Granovetter (1973) argued that weak ties, i.e. the bridges between different stakeholder groups, may be the most valuable for generating new knowledge and identifying new opportunities and hence create a macro effect: 'those to whom we are weakly tied are more likely to move in circles different from our own and will thus have access to information different from that which we receive' (p1371). Applied to ecosystem management, we argue that a loosely connected network involving a diversity of stakeholders is important for gathering different types of ecological knowledge, build moral and political support (legitimacy) from 'non-environmental' sectors, and attain legal and financial support from various institutions and organizations. Hence, if polycentric cross-level institutions provide the structure for adaptive co-management, multiple-overlapping networks of key persons provide the processes.

As an example, Bebbington (1997) identifies brokers as key stewards in sustainable agriculture intensification in the Andes, including their role in coordinating social networks in the management process. In all the cases of sustainable intensification, outsiders have played a key role in bringing in new ideas, but more importantly they have brought in networks of contacts. These brokers had different backgrounds, including a priest, university professor, European volunteers and funding agencies. The connections they brought with them helped the members of the local communities gain access to non-local institutions and resources, including access to NGOs with technical assistance and financial resources, sources of technology, donors, and alternative trading networks. These networks spread across national and international boundaries in ways that would have been hard for the locals to do on their own.

In addition to leaders, we have previously identified other essential actors and actor groups that serve social mechanisms in adaptive co-management networks: knowledge carriers, knowledge generators, stewards and sense-makers. Folke et al (2003), based on several case studies, identified the following actor groups: knowledge retainers, interpreters, facilitators, visionaries, inspirers, innovators, experimenters, followers and reinforcers. In coastal communities of Eastern Africa, actor groups like beach recorders of fish catches and middlemen that link fishers to markets are of major significance in shaping exploitation patterns of coastal and marine ecosystems and thereby influencing the capacity of these social-ecological systems to generate and sustain ecosystem services (de la Torre-Castro, 2006; Crona, 2006). Holling and Chambers (1973), in their analyses of social roles in resource management workshops, stressed the importance of also including individuals with opposite views that oppose and criticize. These roles of actor groups are all important components of social networks and essential for creating the conditions that we argue are necessary for ecosystem management.

Transforming Social-ecological Systems

Crisis, perceived or real, seems to trigger learning and knowledge generation (Westley, 1995) and opens up space for combinations of different social memories and new management trajectories of resources and ecosystems (Gunderson, 2003). Olsson and Folke (2001) described how threats of acidification, overfishing and disease successively initiated learning and generated knowledge and institutions for landscape management among local groups in the Lake Racken catchment in western Sweden. Based on empirical work Olsson et al (2004a) observed the following sequence of local self-organizing toward adaptive co-management of ecosystems.

- A sequence of social responses to environmental events widens the scope of local management from a particular issue or resource to a broad set of issues related to ecosystems processes across scales.
- Management expands from individual actors, to a group of actors to multiple-actor processes.
- Organizational and institutional structures evolve as a response to deal with the broader set of environmental issues.
- Knowledge of ecosystem dynamics develops as a collaborative effort and becomes part of the organizational and institutional structures.
- Social networks develop that connect institutions and organizations across levels and scales and facilitate information flows, identify knowledge gaps and create nodes of expertise of significance for ecosystem management.
- Knowledge for ecosystem management is mobilized through social networks and complements and refines local practice for ecosystem management.
- In the time series of events the ability to deal with uncertainty and surprise is improved which increases the adaptive capacity to deal with future change.

The crises that trigger such self-organization may be caused by external markets and tourism pressure, floods and flood management, shifts in property rights, threats of acidification, resource failures, rigid paradigms of resource management, new legislation or governmental policies that do not take into account local contexts (Berkes et al, 2003). A social-ecological system with low levels of social capital and social memory is vulnerable to such changes and may as a consequence shift into undesired pathways (Gunderson and Holling, 2002).

In contrast, crisis may trigger social capital and social memory to be mobilized and combined into new forms of governance systems with the ability to manage dynamic ecosystems and landscapes. This has been referred to as building social capacity for resilience in social-ecological systems (Folke et al, 2003) and it requires evoking change in social structures (Westley, 1995). Key individuals with strong leadership may catalyse opinion shifts (Gladwell, 2000; Scheffer et al, 2003) and creative teams and actor groups that emerge into a large connected community of practitioners can prepare a social-ecological system for rapid change (Blann et al, 2003; Guimera et al, 2005) and transform it into a new pathway of development.

Transformability means creating and defining a new attractor that directs the development of the social-ecological system by introducing new components and ways of making a living, thereby changing the state variables, and often the scales of key cycles, that define the system (Walker et al, 2004).

Transformations toward alternative forms of governance has been addressed by Kettl (2000), Kuks and Bressers (2004) and Agrawal (2005). Olsson et al (2004b) analysed the emergence of a governance system for adaptive co-management of the wetland landscape of Kristianstad in southern Sweden, a process where unconnected management by several actors in the landscape was mobilized, renewed and moved into a new configuration of ecosystem management within about a decade.

The self-organizing process was triggered by the perceived threats to the area's cultural and ecological values among people of various local steward associations and local government. A key individual provided visionary leadership in directing change and transforming governance. The transformation involved four phases

1 preparing the system for change;
2 the opening of an opportunity;
3 navigating the transition;
4 charting a new direction for building resilience of the new governance regime.

Trust-building dialogues, mobilization of social networks with actors and teams across scales, coordination of ongoing activities, sense-making, collaborative learning and creating public awareness were part of the process. A comprehensive framework with a shared vision and goals that presented ecosystem management as development and turned problems into opportunities was developed and contributed to a shift in values and meaning of the broader agricultural-urban-wetland landscape among key actors. When a window of opportunity at the political level opened, it was possible to tip and transform the governance system into a trajectory of adaptive co-management with extensive social networks of practitioners engaged in multi-level governance. The transformation took place within the existing legal and formal institutional framework (Hahn et al, 2006). Currently adaptive capacity is built to make the new social-ecological configuration resilient to change. Strategies for adaptive capacity are presented in Table 7.3.

Understanding the sources of resilience that allow for mobilization of social capital and memory to generate novelty and innovation for transformation of social-ecological systems into improved pathways of development is a central issue for sustainability research.

Conclusions

We have only scratched the surface of an immense research challenge that promises to provide a much richer understanding of not just human–environment interactions but of how the world we live in actually works and the implications it has for current policies and governance. The chapter emphasizes that the social landscape should be approached as carefully as the ecological in order to clarify features that contribute to the resilience of social-ecological systems. In this context, Pretty and Ward (2001) find that relations of trust, reciprocity, common rules, norms and sanctions, and connectedness in institutions are critical. We have similar findings that include vision, leadership and trust; enabling legislation that creates social space for ecosystem management; funds for responding to environmental change and for remedial action; capacity for monitoring and responding to environmental

Table 7.3 *Processes and strategies in Kristianstads Vattenrike that increase capacity for dealing with uncertainty and change*

Developing motivation and values for ecosystem management
• Envisioning the future together with actors • Developing, communicating and building support for the mission • Identifying and clarifying objectives • Developing personal ties • Establishing a close relationship and trust with key individuals • Fostering dialogue with actors • Providing arenas for trust-building among actors • Building trust in times of stability to facilitate conflict resolution • Developing norms to avoid loss of trust among actors • Continuously communicating success and progress of projects
Directing the local context through adaptive co-management
• Encouraging and supporting actors to perform monitoring, including inventories • Encouraging and supporting actors to manage ecosystem processes for biodiversity and ecosystem services • Initiating and sustaining social networks of key individuals • Mobilizing individuals of social networks in problem-driven projects • Making sense of and guiding the management process • Synthesizing and mobilizing knowledge for ecosystem management • Providing coordination of project and arenas for collaboration • Encouraging and inspiring actors to voluntary participation • Initiating projects and selecting problems that can be turned into possibilities • Creating public opinion and involving local media
Navigating the larger environment
• Influencing decision makers at higher levels to maintain governance structures that allow for adaptive co-management of the area • Mobilizing new funding when needed • Mobilizing external knowledge when needed • Exchanging information and collaboration with local steward associations in Sweden and internationally • Collaborating with national and international scientists • Collaborating with national and international non-governmental organizations • Participating in international institutional frameworks • Supporting diffusion of the values of KV through social networks • Providing a buffer for external drivers • Communicating with national media

Source: Adapted from Olsson et al, 2004b

feedback; information flow through social networks; the combination of various sources of information and knowledge; sense-making and arenas of collaborative learning for ecosystem management. Our work illustrates that the interplay between individuals (e.g. leadership, teams, actor groups), the emergence of nested organizational structures, institutional dynamics and power relations tied together in dynamic social networks are examples of features that seem critical in adaptive governance that allows for ecosystem management and for responding to environmental feedback across scales.

An important lesson from the research is that it is not enough to create arenas for dialogue and collaboration, nor is it enough to develop networks to deal with issues at a landscape level. Further investigation of the interplay between key individuals, actor groups, social networks, organizations and institutions in multi-level social-ecological systems in relation to adaptive capacity, cross-scale interactions and enhancement of resilience is needed. We have to understand, support and perhaps even learn how to actively navigate the underlying social structures and processes in the face of change. There will be inevitable and possibly large-scale environmental changes and preparedness has to be built to enhance the social-ecological capacity to respond, adapt to and shape our common future and make use of creative capacity to find ways to transform into pathways of improved development. We conclude that the existence of transformative capacity is essential in order to create social-ecological systems with the capability to manage ecosystems sustainably for human well-being. Adaptive capacity will be needed to strengthen and sustain such systems in the face of external drivers and events.

Agroecology and Agroecosystems

Stephen R. Gliessman

Agriculture is more than an economic activity designed to produce a crop or to make as large a profit as possible on the farm. A farmer can no longer pay attention to the objectives and goals for his or her farm only and expect to adequately deal with the concerns of long-term sustainability. Discussions about sustainable agriculture must go far beyond what happens within the fences of any individual farm. Farming is now viewed as a much larger system with many interacting parts, including environmental, economic and social components (Gliessman, 2001; Flora, 2001). It is the complex interaction and balance among all of these parts that has brought us together to discuss sustainability, to determine how to move toward this broader goal, and to learn how an agroecological perspective focused on sustainable agroecosystems is a way to achieve these long-term objectives.

Much of modern agriculture has lost the balance needed for long-term sustainability (Kimbrell, 2002). With their excessive dependence on fossil fuels and external inputs, most industrialized agroecosystems are overusing and degrading the soil, water, genetic and cultural resources upon which agriculture has always relied. Problems in sustaining agriculture's natural resource foundation can only be masked for so long by modern practices and high input technologies. In a sense, as we borrow ever-increasing amounts of water and fossil fuel resources from future generations, the negative impacts on farms and farming communities will continue to become more evident. The conversion to sustainable agroecosystems must become our goal (Gliessman, 2001).

In an attempt to clarify my own thinking about agroecosystems, I often think of agriculture as a stream, and farms are different points along that stream. When we think of an individual farm as a 'pool' in a calm eddy at some bend in the stream's flow, we can imagine how many things 'flow' into a farm, and we also expect that many things flow out of it as well. As a farmer, I work hard to keep my pool in the stream (my farm) clean and productive. I try to be as careful as possible in terms of how I care for the soil, which crops I plant, how I control pests and diseases, and how I market my harvest. Back in the days when there were fewer farms, fewer people to

Reprinted from Gliessman S. 2004. Agroecology and agroecosystems, in American Society of Agronomy Monograph (Rickert D and Francis C (eds)). *Agroecosystem Analysis.* Agronomy Monograph series # 43, pp19–29. Reproduced with permission from American Society of Agronomy.

feed and smaller demands on farmers and farmland, I could keep my farm in pretty good shape. I could keep my pool in the stream pretty clean and did not have to worry very much about what was going on 'downstream' from my farm.

But such a strategy has become much more difficult today. I find that I have less and less control over what comes into my pool. I face a variety of 'upstream impacts' that in combination can threaten the sustainability of my farm. These include the inputs into my farm that either I purchase or which arrive from the surrounding area. They include labour availability and cost, market access for what I produce, legislated policies that determine how much water I use, pesticides I apply, or how I care for my animals – not to mention the vagaries of the weather! My pool can become quickly muddied.

I must also increasingly consider how the way I take care of my pool can have 'downstream effects' in the stream below. Soil erosion and groundwater depletion can negatively affect farms other than my own. Inappropriate or inefficient use of pesticides and fertilizers can contaminate the water and air, as well as leave potentially harmful residues on the food that my family and others will consume. How well I do on my farm is reflected in the viability of rural farm economies, our local community and society broadly. Key indicators are the losses of farmland to other activities and the loss of family farms in general. Both upstream and downstream factors are linked in complex ways, often beyond my control, and they impinge upon the sustainability of my farm.

The Agroecology Perspective

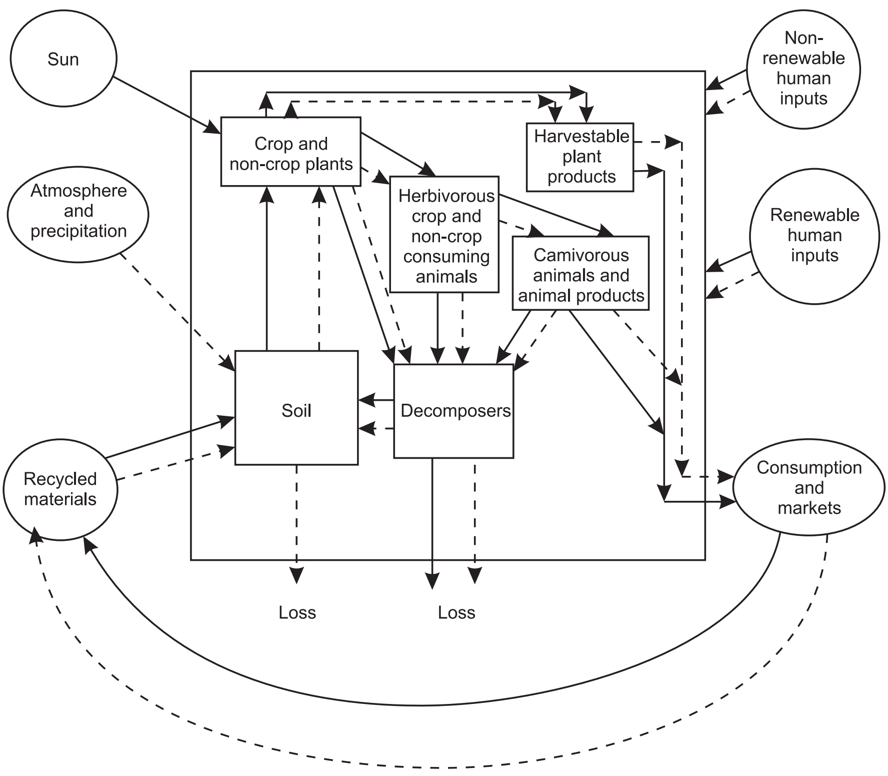
The agroecosystem

Any definition of sustainable agriculture must include how we examine the production system as an agroecosystem. We need to look at the entire system, the entire stream in the above analogy. This definition must move beyond the narrow view of agriculture that focuses primarily on the development of practices or technologies designed to increase yields and improve profit margins. These practices and technologies must be evaluated on their contributions to the overall sustainability of the farm system. The new technologies have little hope of contributing to sustainability unless the longer-term, more complex impacts of the entire agricultural system are included in the evaluation. The agricultural system is an important component of the larger food system (Francis et al, 2003).

A primary foundation of agroecology is the concept of the ecosystem, defined as a functional system of complementary relations between living organisms and their environment, delimited by arbitrarily chosen boundaries, which in space and time appears to maintain a steady yet dynamic equilibrium (Odum, 1996; Gliessman, 1998). Such an equilibrium can be considered to be sustainable in a definitive sense. A well-developed, mature natural ecosystem is relatively stable, self-sustaining, recovers from disturbance, adapts to change, and is able to maintain productivity through using energy inputs of solar radiation alone. When we expand the ecosystem concept to agriculture and consider farm systems as agroecosystems, we have a basis for looking beyond a primary focus on traditional and easily measured system outputs (yield or economic return). We can instead look at the complex set of biological, physical, chemical, ecological and cultural interactions determining the processes that permit us to achieve and sustain yields.

Agroecosystems are often more difficult to study than natural ecosystems because they are complicated by human management, which alters normal ecosystem structures and functions. There is no disputing the fact that for any agroecosystem to be fully sustainable, a broad series of interacting ecological, economic and social factors and processes must be taken into account. Still, ecological sustainability is the building block upon which other elements of sustainability depend.

An agroecosystem is created when human manipulation and alteration of an ecosystem take place for the purpose of establishing agricultural production. This introduces several changes in the structure and function of the natural ecosystem (Figure 8.1) and resulting changes in a number of key system-level qualities. These



Note: Solid lines are energy flow, and dotted lines are nutrient cycles. This model assumes that nutrients and leftover energy are returned to the agroecosystem as reusable materials, and that the use of non-renewable human inputs is minimized.

Figure 8.1 *Functional and structural components of an ecosystem converted to a sustainable agroecosystem* qualities are often referred to as the emergent qualities or properties of systems, qualities that manifest themselves once all of the component parts of the system are organized. These same qualities can also serve as indicators of agroecosystem sustainability (Gliessman, 2001). Four key emergent qualities of ecosystems and how they are altered as they are converted to agroecosystems are discussed in the following sections.

Energy flow

Energy flows through a natural ecosystem as a result of complex sets of trophic interactions, with certain amounts being dissipated at different stages along the food chain, and with the greatest amount of energy within the system ultimately moving along the detritus pathway (Odum, 1971). Annual production of the system can be calculated in terms of net primary productivity or biomass, each component with its corresponding energy content. Energy flow in agroecosystems is altered greatly by human interference (Rappaport, 1971; Pimentel and Pimentel, 1997). Although solar radiation is obviously the major source of energy, many inputs are derived from human-manufactured sources and are most often not self-sustaining. Agroecosystems too often become through-flow systems, with a high level of fossil fuel input and considerable energy directed out of the system at the time of each harvest. Biomass is not allowed to otherwise accumulate within the system or contribute to driving important internal ecosystem processes (e.g. organic detritus returned to the soil serving as an energy source for microorganisms that are essential for efficient nutrient cycling). For sustainability to be attained, renewable sources of energy must be maximized, and energy must be supplied to fuel the essential internal trophic interactions needed to maintain other ecosystem functions.

Nutrient cycling

Small amounts of nutrients continually enter an ecosystem through several hydrogeochemical processes. Through complex sets of interconnected cycles, these nutrients then circulate within the ecosystem, where they are most often bound in organic matter (Borman and Likens, 1967). Biological components of each system become very important in determining how efficiently nutrients move, ensuring that minimal amounts are lost from the system. In a mature ecosystem, these small losses are replaced by local inputs, maintaining a nutrient balance. Biomass productivity in natural ecosystems is linked very closely to the annual rates at which nutrients are able to be recycled. In an agroecosystem, recycling of nutrients can be minimal, and considerable quantities are lost from the system with the harvest or as a result of leaching or erosion due to a great reduction in permanent biomass levels held within the system (Tivy, 1990). The frequent exposure of bare soil between crop plants during the season, or in open fields between cropping seasons, creates 'leaks' of nutrients from the system. Modern agriculture has come to rely heavily upon nutrient inputs derived or obtained from petroleum-based sources to replace these losses. Sustainability requires that these leaks be reduced to a minimum and recycling mechanisms be reintroduced and strengthened. Ultimately, human societies need to find ways to return nutrients consumed in agricultural products back to the fields, the agroecosystems that consumed and produced them in the first place.

Population regulating mechanisms

Through a complex combination of biotic interactions and limits set by the availability of physical resources, population levels of the various organisms are controlled, and thus eventually link to and determine the productivity of an ecosystem. Selection through time tends toward the establishment of the most complex structure biologically possible within the limits set by the environment, permitting the establishment of diverse trophic interactions and niche diversification. Due to human-directed genetic selection and domestication, as well as the overall simplification of agroecosystems (i.e. the loss of niche diversity and a reduction in trophic interactions), populations of crop plants or animals are rarely self-reproducing or self-regulating. Human inputs in the form of seed or control agents, often dependent on large energy subsidies, determine population sizes. Biological diversity is reduced, natural pest control systems are disrupted, and many niches or microhabitats are left unoccupied. The danger of catastrophic pest or disease outbreak is high, often despite the availability of intensive human interference and inputs. A focus on sustainability requires the reintroduction of the diverse structures and species relationships that permit the functioning of natural control and regulation mechanisms. We must learn to work with and profit from diversity, rather than focus on agroecosystem simplification.

Dynamic equilibrium

The species richness or diversity of mature ecosystems permits a degree of resistance to all but very damaging perturbations. In many cases, periodic disturbances ensure the highest diversity, and even highest productivity (Connell, 1978). System stability is not a steady state, but rather a dynamic and highly fluctuating one that permits ecosystem recovery following disturbance. This promotes the establishment of an ecological equilibrium that functions on the basis of sustained resource use which the ecosystem can maintain indefinitely and which can even shift if the environment changes. At the same time, rarely do we witness what might be considered large-scale disease outbreaks in healthy, balanced ecosystems. With a reduction of natural structural and functional diversity, much of the resilience of the system is lost, and constant human-derived external inputs must be maintained. An overemphasis on maximizing harvest outputs upsets the former equilibrium and leads to a dependence on outside interference. To reintegrate sustainability, the emergent qualities of system resistance and resiliency must once again play a determining role in agroecosystem design and management.

We need to be able to analyse both the immediate and future impacts of agroecosystem design and management so we can identify the key areas in each system on which to focus the search for alternatives or solutions to problems. We must learn to be more competent in our agroecological analysis in order to avoid problems or negative changes before they occur, rather than struggling to reverse the problems after they have been created. The agroecological approach provides us one such alternative (Altieri, 1995; Gliessman, 1998).

Applying Agroecology

The process of understanding agroecosystem sustainability has its foundations in two kinds of ecosystems: natural ecosystems and traditional (also known as local or indigenous) agroecosystems. Both provide ample evidence of having passed the test of time in terms of long-term productive ability, but each offers a different knowledge base from which to understand this ability. Natural ecosystems are reference systems for understanding the ecological basis for sustainability in a particular location. Traditional agroecosystems provide many examples of how a culture and its local environment have co-evolved with time through processes that balance the needs of people, expressed as ecological, technological, and socioeconomic factors. Agroecology, defined as the application of ecological concepts and principles to the design and management of sustainable agroecosystems (Gliessman, 1998), draws on both to become a research approach that can be applied to converting unsustainable and conventional agroecosystems into sustainable ones.

Natural ecosystems reflect a long period of evolution in the use of local resources and adaptation to local ecological conditions. They have each become complex sets of plants and animals that co-inhabit a given environment, and as a result, provide extremely useful information for the design of more locally adapted agroecosystems. As I have suggested (Gliessman, 1998), 'the greater the structural and functional similarity of an agroecosystem to the natural ecosystems in its biogeographical region, the greater the likelihood that the agroecosystem will be sustainable'. If this suggestion holds true, natural ecosystem structures and functions can be used as benchmarks or threshold values for more sustainable systems. Scientists have begun to explore how an understanding of natural ecosystems can be used to guide our search for sustainable agroecosystems that respect and protect the environment and natural resources (Soule and Piper, 1992; Jackson and Jackson, 2002).

Traditional and indigenous agroecosystems are different from conventional systems in that they developed originally in times or places where inputs other than human labour and local resources were generally not available or desirable to the local people. Production takes place in ways that demonstrate people's concerns about long-term sustainability of the system, rather than solely maximizing output and profit. Traditional systems continue to be important as the primary sources of food production for a large part of the populations of many developing countries, while at the same time maintaining their foundations in ecological knowledge (Wilken, 1988; Altieri, 1990). This reality demonstrates their importance for the development of sustainable agroecosystems. This is especially true today when so many modern conventional agroecosystems have caused severe degradation of their ecological foundations, as socioeconomic factors have become the predominant forces in the food system (Altieri, 1990). Many traditional agroecosystems are actually very sophisticated examples of the application of ecological knowledge, and can serve as the starting point for the conversion to more sustainable agroecosystems in the future. The traditional Mesoamerican intercrop of corn (*Zea mays* L.), bean and squash is a well-known cropping system where higher yields in the mixtures come about due to a complex of interactions among components of the agroecosystem (Amador and Gliessman, 1990). Examples of such interactions range from the increased presence of beneficial insects due to attractive microclimates and a greater abundance of pollen and nectar sources (Letourneau, 1986), to biologically fixed nitrogen being made available to corn through mycorrhizal fungi connections with roots of bean (Bethlenfalvay et al, 1991).

How can agroecology link our understanding of natural ecosystem structure and function with the knowledge inherent in traditional agroecosystems? On the one hand, the knowledge of place that comes from understanding local ecology is an essential foundation. Another is the local experience with farming that has its roots in many generations of living and working within the limits of that place. We put both of these approaches together when we work with farmers going through the transition process to more environmentally sound management practices, and thus realize the potential for contributing to long-term sustainability. This transition is already occurring. Many farmers, despite the heavy economic pressure on agriculture, are in the process of converting their farms to more sustainable design and management (National Research Council, 1989; OAC/SCOAR, 2003). In California the dramatic increase in organic acreage for a range of crops has been based largely on farmer innovation (Swezey and Broome, 2000). It is incumbent that agroecologists play an important role in contributing to this conversion process.

Converting an agroecosystem to a more sustainable design is a complex process. It is not just the adoption of a new practice or a new technology. There are no silver bullets. Instead, this conversion uses the agroecological approach described above. The farm is perceived as part of a larger system of interacting parts, an agroecosystem. We must focus on redesigning that system in order to promote the functioning of an entire range of different ecological processes (Gliessman, 1998). In a study of the conversion of conventional strawberries (*Fragaria Ananassa* Rozier) to organic management, several changes were observed (Gliessman et al, 1996). As the use of synthetic chemical inputs was reduced or eliminated and recycling was emphasized, agroecosystem structure and function changed as well. A range of processes and relationships began to transform, beginning with improvement in basic soil structure, an increase in soil organic matter content, and greater diversity and activity of beneficial soil biota. Major changes began to occur in the activity and relationships among weed, insect and pathogen populations, and in the functioning of natural control mechanisms. For example, predatory mites

Table 8.1 *Guiding principles for the process of conversion to sustainable agroecosystems design and management*

- Shift from through-flow nutrient management to recycling of nutrients, with increased dependence on natural processes, such as biological N fixation and mycorrhizal relationships
- Use renewable sources of energy instead of non-renewable sources
- Eliminate the use of non-renewable off-farm human inputs that have the potential to harm the environment or the health of farmers, farm workers or consumers
- When materials must be added to the system, use naturally occurring materials instead of synthetic, manufactured inputs
- Manage pests, diseases and weeds instead of 'controlling' them
- Re-establish the biological relationships that can occur naturally on the farm instead of reducing and simplifying them
- Make more appropriate matches between cropping patterns and the productive potential and physical limitations of the farm landscape
- Use a strategy of adapting the biological and genetic potential of agricultural plant and animal species to the ecological conditions of the farm rather than modifying the farm to meet the needs of the crops and animals
- Value most highly the overall health of the agroecosystem rather than the outcome of a particular crop system or season
- Emphasize conservation of soil, water, energy and biological resources
- Incorporate the idea of long-term sustainability into overall agroecosystem design and management

Source: modified from Gliessman, 1998

gradually replaced the use of synthetic acaracides for the control of two-spotted spider mites (*Tetranychus urticae* Koch), the most common arthropod pest in strawberries in California.

Ultimately, nutrient dynamics and cycling, energy use efficiency and overall agroecosystem productivity are affected. Changes may be required in day-to-day management of the farm, planning, marketing and even philosophy. The specific needs of each agroecosystem will vary, but the principles for conversion listed in Table 8.1 can serve as general guidelines for working through the transition. It is the role of the agroecologist to help the farmer measure and monitor these changes during the conversion period in order to guide, adjust and evaluate the conversion process. Such an approach provides an essential framework for determining the requirements for and indicators of sustainable agroecosystem design and management.

Comparing ecosystems and agroecosystems

The key to developing sustainability is building a strong ecological foundation under the agroecosystem, using the ecosystem knowledge inherent to agroecology as discussed above. This foundation then serves as the framework for producing the sustainable harvests needed by humans. In order to maintain sustainable harvests, though, human management is a requirement. Agroecosystems are not self-sustaining, but rely on natural processes for maintenance of their productivity. An agroecosystem's resemblance to natural ecosystems allows the system to be sustained, in spite of the long-term human removal of biomass, without large subsidies of non-renewable energy and without detrimental effects on the surrounding environment.

Table 8.2 compares natural ecosystems with three types of agroecosystems in terms of several ecological criteria. Traditional agroecosystems most closely resemble natural ecosystems, since they most often are focused on the use of locally available and renewable resources, local use of agricultural products and the return of biomass to the farming system. Sustainable agroecosystems are very similar in many properties, but they are more dissimilar in others because of the probable focus on export of harvest to distant markets, the need to purchase a significant part of their nutrients externally and the much stronger impact of market systems on agroecosystem diversity and management. Compared with conventional systems, sustainable agroecosystems have somewhat lower and more variable yields

Table 8.2 *Emergent properties of natural ecosystems, traditional agroecosystems, conventional agroecosystems and sustainable agroecosystems*

Emergent ecological property	*Natural ecosystem*	*Agroecosystem type*

due to the weather variation that occurs from year to year. Such reductions in yields can be more than offset, from the perspective of sustainability, through the advantages gained in reduced dependence on external inputs, more reliance on natural controls of pests, and reduced negative off-farm impacts of farming activities.

Future Perspectives

Problems in agriculture create the pressures for the changes that will bring about a sustainable agriculture. However, it is one thing to express the need for sustainability, and quite another to actually quantify it and bring about the changes that are required. Designing and managing sustainable agroecosystems, as an approach, is in its formative stages. Initially it builds upon the fields of ecology and agricultural science and is emerging as the science of agroecology. This combination can play an important role in developing the understanding necessary for a transition to sustainable agriculture.

But sustainable agriculture is more. It takes on a cultural perspective as the concept expands to include humans and their impacts on agricultural environments. Agricultural systems are a result of the co-evolution that occurs between culture and environment, and a sustainable agriculture values the human as well as the ecological components. Our small pool in the stream becomes the focal point for changing how we do agriculture, but that change must occur in the context of the human societies within which agriculture is practised, the whole stream in our analogy.

All agricultural systems can no longer be viewed as strictly production activities driven primarily by economic pressures. We need to re-establish an awareness of the strong ecological foundation upon which agriculture originally developed and ultimately depends. Too little importance has been given to the 'downstream' effects that are manifest off the farm, either by surrounding natural ecosystems or by human communities. We need an interdisciplinary basis upon which to evaluate these impacts.

In the broader context of sustainability, we must study the environmental background of the agroecosystem, as well as the complex of processes involved in the maintenance of long-term productivity. We must first establish the ecological basis of sustainability in terms of resource use and conservation, including soil, water, genetic resources and air quality. Then we must examine the interactions among the many organisms of the agroecosystem, beginning with interactions at the individual species level and culminating at the ecosystem level as our understanding of the dynamics of the entire system is revealed.

Our understanding of ecosystem-level processes should then integrate the multiple aspects of the social, economic and political systems within which agroecosystems function, making them even more complex systems. Such an integration of ecosystem and social system knowledge about agricultural processes will not only lead to a reduction in synthetic inputs used for maintaining productivity; it will also permit the evaluation of such qualities of agroecosystems as the long-term effects of different input–output strategies, the importance of the environmental services provided by agricultural landscapes, and the relationship between economic and ecological components of sustainable agroecosystem management. By properly selecting and understanding the 'upstream' inputs into agriculture, we can be assured that what we send 'downstream' will promote a sustainable future.

Ecological Basis for Low-Toxicity Integrated Pest Management (IPM) in Rice and Vegetables

Kevin Gallagher, Peter Ooi, Tom Mew, Emer Borromeo, Peter Kenmore and Jan-Willem Ketelaar

Introduction

This chapter focuses on two case studies primarily arising from Asian-based Integrated Pest Management (IPM) programmes. One case study provides an in-depth analysis of well researched and widespread rice-based IPM while the second study focuses on emergent vegetable IPM.

The powerful forces that drive these two systems could not be more different. Rice production is a highly political national security interest that has often justified heavy handed methods in many countries to link high yielding varieties, fertilizers and pesticides to credit or mandatory production packages and led to high direct or indirect subsidies for these inputs. Research, including support for national and international rice research institutes, was well-funded to produce new varieties and basic agronomic and biological data. Vegetable production on the other hand has been led primarily by private sector interests and local markets. Little support for credit, training or research has been provided. High usage of pesticides on vegetables has been the norm due to lack of good knowledge about the crop, poorly adapted varieties and a private sector push for inputs at the local kiosks to tackle exotic pests on exotic varieties in the absence of well-developed management systems.

However, other pressures are now driving change to lower pesticide inputs on both crops. Farmers are more aware of the dangers of some pesticides to their own health and their production environment. The rise of Asian incomes has led to a rise in vegetable consumption that has made consumers more aware of food safety. Cost of inputs is another factor as rice prices fall and input prices climb. More farmers are

Reprinted from Gallagher K, Ooi P, Mew T, Borromeo E, Kenmore P and Ketelaar J-W. 2005. Ecological basis for low-toxicity Integrated Pest Management (IPM) in rice and vegetables. In Pretty J (ed). *The Pesticide Detox.* Earthscan, London.

producing vegetables for urban markets, so driving competition to lower input costs as well. Highly variable farm-gate prices for vegetables make farmers' economic decisions to invest in pesticide applications a highly risky business. Research on vegetables is beginning to catch up with rice allowing for better management of pests through prevention and biological controls. IPM programmes in both crops aim to reduce the use of toxic pesticide inputs and the average toxicity of pest management products that are still needed whilst improving profitability of production.

Integrated Pest Management in Rice

This chapter has been prepared to provide a conceptual guide to the recent developments in rice Integrated Pest Management (IPM) within an ecological framework. It is not a 'how to' guide but rather a 'why to' guide for IPM programmes that are based on ecological processes and work towards environmentally friendly and profitable production. We provide a broad overview of IPM practices in rice cultivation including its ecological basis, decision making methods, means of dissemination to farmers and future needs to improve these practices. The breadth of pest problems, including interaction with soil fertility and varietal management are discussed in depth. Although the main focus is on Asian rice cultivation, we also provide examples of rice IPM being applied in other regions.

IPM in rice has been developing in many countries since the early 1960s. However, much of the development was based on older concepts of IPM including intensive scouting and economic thresholds that are not applicable under all conditions (Morse and Buhler, 1997) or for all pests (e.g. diseases, weeds), especially on smallholder farms where the bulk of the world's rice is grown and which are often under a weak or non-existing market economy. During the 1980s and 1990s, important ecological information became available on insect populations that allowed the development of a more comprehensive ecological approach to pest management, as well as greater integration of management practices that went beyond simple scouting and economic threshold levels (Kenmore et al, 1984; Gallagher, 1988; Ooi, 1988; Graf et al, 1992; Barrion and Litsinger, 1994; Rubia et al, 1996; Settle et al, 1996).

Since then, an ecological and economic analytical approach has been taken for management to consider crop development, weather, various pests and their natural enemies. These principles were first articulated in the Indonesian National IPM Programme, but have expanded as IPM programmes have evolved and improved. Currently programmes in Africa and Latin America now use the term Integrated Production and Pest Management (IPPM), and follow these principles: grow a healthy soil and crop; conserve natural enemies; observe fields regularly (soil, water, plant, pests, natural enemies); and farmers should strive to become experts. Within these principles, economic decision making is still the core of rice IPM but incorporates good farming practices as well as active pest problem solving within a production context.

IPM in rice seeks to optimize production and to maximize profits through its various practices. To accomplish this, however, decision making must always consider both the costs of inputs and the ecological ramifications of these inputs. A particular characteristic of Asian rice ecosystems is the presence of a potentially damaging secondary pest, the rice brown planthopper (BPH), *Nilaparvata lugens* (see Box 9.1). This small but mighty insect has in the past occurred in large-scale outbreaks and caused disastrous losses (IRRI, 1979). These outbreaks were pesticide-induced and triggered by pesticide subsidies and policy mismanagement (Kenmore, 1996). BPH is still a localized problem, especially where pesticide overuse and abuse is common, and therefore can be considered as an ecological focal point around which both ecological understanding and management are required for profitable and stable rice cultivation. BPH also becomes the major entry point for all IPM educational programmes since it is always necessary to prevent its outbreak during crop management. Other pests which interact strongly with the

Box 9.1 *The brown planthopper (BPH)*

The brown planthopper (BPH), *Nilaparvata lugens* Stål (Delphacidae, Homoptera), is an insect that has been associated with rice since the crop was grown for food in Asia. This insect is known to survive well only on rice and in evolutionary terms has co-evolved with the rice plant.

Rice fields are invaded by macropterous adults. Upon finding a suitable host, female BPH will lay eggs into the stem and leaf stalks. The egg stage lasts from six to eight days. Nymphs resemble adults except for size and lack of wings. There are five nymphal stages. The complete life cycle lasts 23–25 days. When food is suitable, the next generation of adults are often brachypterous or short winged. Both nymphs and adults prefer to be at the base of rice plants. BPH feeds by removing sap from rice plants, preferably from the phloem.

Usually, populations of BPH are kept low by the action of a wide range of natural enemies indigenous to tropical rice ecosystems in Asia. Outbreaks reported in the tropics during the 1970s were associated with regular use of insecticides. The more effective the insecticide, the faster the resurgence of BPH populations which led to a large-scale dehydration of rice plants, a symptom known as 'hopperburn'. Insecticides removed both BPH as well as their predators and parasitoids. However, eggs laid inside the stem are relatively unharmed by spraying and, when these hatch, BPH nymphs develop in an environment free of predators. In unsprayed fields, the population of BPH did not increase to any significant level, suggesting the importance of biological control. Today, farmers learn about predators by carrying out experiments and when they discover the role of these natural enemies, they are less likely to use insecticides. In Indonesia, Presidential Decree 3/86 provided the framework and support for farmers to understand and conserve natural enemies and this has in turn helped rice fields in Indonesia to be relatively free of BPH in the last ten years. This has coincided with an extensive programme to educate farmers based on the Farmer Field School model.

management of inputs are rice stemborers and the various diseases discussed below.

A major issue when considering IPM decision making is one of paths to rice production intensification. In most cases, intensification means the use of improved high yielding varieties, irrigation, fertilizers and pesticides – as was common in the Green Revolution. However, two approaches to intensification should be considered. The first is input intensification in which it is important to balance an optimal production level against maximizing profits and for which higher inputs can destabilize the production ecosystem. The second route to intensification is one of optimizing all outputs from the rice ecosystem to maximize profits. In many lowland flooded conditions, this may mean systems such as rice–fish or rice–duck that may be more profitable and less risky, yet require lower inputs (and often resulting in lower rice yields). In areas where inputs are expensive, where the ecosystem is too unstable (because of drought, flood) to ensure recovery of input investments, or where rice is not marketed, then such a path to intensification may be more beneficial over time. However, such a system has a different ecology due to the presence of fish or duck, and therefore will involve a different type of IPM decision making.

Ecological Basis of Rice IPM

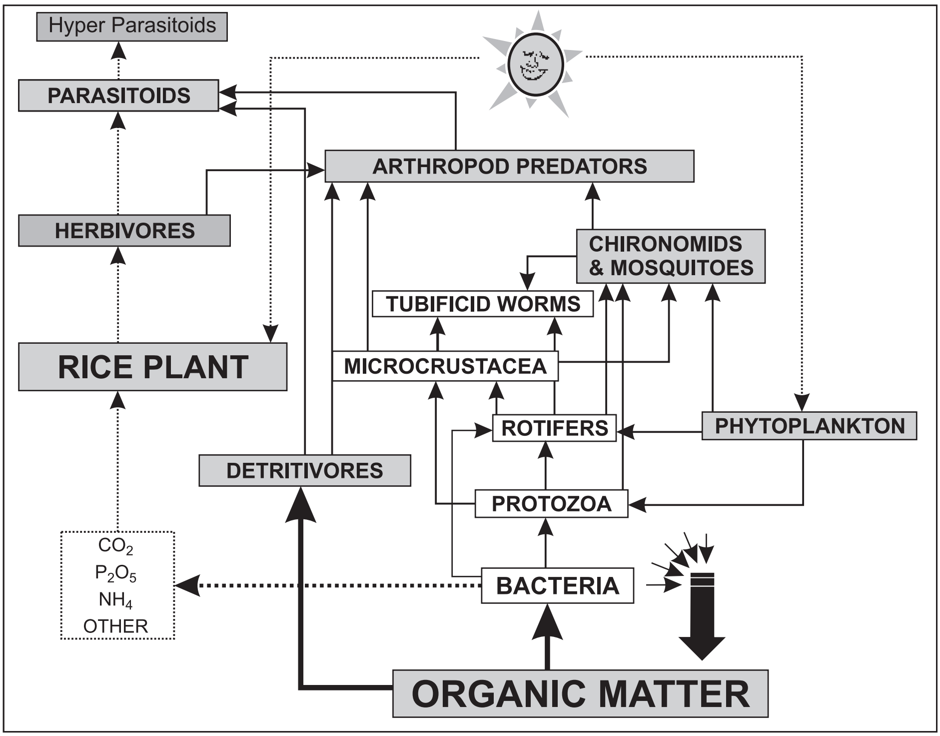
IPM in much of Asian rice is now firmly based on an ecological understanding of the crop and its interaction with soil nutrients and crop varieties. We present below an ecological overview of our current understanding of how the rice ecosystem operates during the development of the crop.

The rice ecosystem in Asia is indigenous to the region and its origins of domestication date back 8000 years to the Yangtze Valley in southern China (Smith, 1995), and more widely some 6000 years ago (Ponting, 1991). Cultivation practices similar to those of today were reached by the 16th century (Hill, 1977). This period of time means that rice plants, pests and natural enemies existed and coevolved together for thousands of generations. Rice ecosystems typically include both a terrestrial and an aquatic environment during the season with regular flooding from irrigation or rainfall. These two dimensions of the rice crop may account for the extremely high biodiversity found in the rice ecosystem and its stability even under intensive continuous cropping – and contrasts with the relative instability of rice production under dryland conditions (Cohen et al, 1994). The irrigated rice systems in Africa, the Americas and Europe also include this aquatic and terrestrial element within which high levels of biodiversity are also found.

Insects

Studies by Settle and farmer research groups in Indonesia (Settle et al, 1996) show that flooding of fields triggers a process of decomposition and development of an aquatic foodweb, which results in large populations of detritus-feeding insects (especially Chironomid and ephydrid flies). These insects emerge onto the water surface and into the rice canopy in large numbers, very early in the growing season, providing critical resources to generalist predator populations long before 'pest' populations have developed (Figure 9.1).

This is quite different from the usual predator–prey models taught in most basic IPM courses and provides a mechanism to suggest that natural levels of pest



Organic matter drives the development of high early-season populations of predators through parallel pathways: (1) microorganisms (zooplankton and phytoplankton) are fed on by filter-feeders (mosquitoes and midges), and (2) organic matter directly feeds detritus-feeding insects (Diptera larvae, Collembola, and some Coleoptera larvae). Each of three pathways dominates at different times of the season: microorganism/filter-feeders early-season; plant/herbivore mid-season; and detritivores post-harvest. The pattern of interaction leads to consistently high populations of generalist predators early in the growing season, and low and stable populations of herbivores later in the season.

Source: After Settle and Whitten, 2000

Figure 9.1 *Hypothesized flow of energy in tropical rice ecosystems* control in tropical irrigated rice ecosystems are far more stable and robust than purely terrestrial agroecosystems. This stability, however, was found to be lower in rice landscapes that are subject to long (more than three month) dry seasons and where rice is planted in large-scale synchronous monocultures, as well as in areas where farmers use pesticides intensively. Increased amounts of organic matter in the soil of irrigated rice fields, by itself a highly valuable practice for sustainable nutrient management, has the additional advantage of boosting both populations of detritus-feeding insects and insect predators, and thereby improving natural levels of pest control (Settle et al, 1996).

A second consideration for rice IPM is the ability of most rice varieties to compensate for damage. The rice plant rapidly develops new leaves and tillers early in the season replacing damaged leaves quickly. The number of tillers produced is always greater than the number of reproductive tillers allowing for some damage of vegetative tillers without affecting reproductive tiller number. The flag leaf contributes to grain filling but the second leaf provides photosynthates as well, while lower leaves are actually a sink that compete with the panicle. Finally, photosynthates appear to move from damaged reproductive tillers to neighbouring tillers so that total hill yield is not as severely impacted as expected when a panicle is damaged by stemborers.

Thus, early season defoliators (such as whorl maggot, case worms and armyworms) cause no yield loss up to approximately 50 per cent defoliation during the first weeks after transplanting (Shepard et al, 1990; Way and Heong, 1994) although higher damage occurs when water control is difficult. As early tillering is also higher than what the plant can ultimately support reproductively, up to 25 per cent vegetative tiller damage by stemborers ('deadhearts') (caused by *Scirpophaga* spp., *Chilo* spp. and *Sesamia* spp.) can be tolerated without significant yield loss (Rubia et al, 1996). Significant damage (above 50 per cent) to the flag leaf by leaffolders (*Cnaphalocrocis mdeinalis* and *Marasmia* spp.) during panicle development and grain filling can cause significant yield loss, although this level of damage is uncommon where natural enemies have been conserved (Graf et al, 1992). Late season stemborer damage (white heads) also causes less damage than previously expected such that up to 5 per cent white heads in most varieties does not cause significant yield loss (Way and Heong, 1994; Rubia et al, 1996).

The conspicuous rice bug (*Leptocorisa oratorius*) is another major target for insecticide applications. However, in a recent study involving farmers and field trainers at 167 locations, van den Berg and Soehardi (2000) have demonstrated that the actual yield loss in the field is much lower than previously assumed. The rice panicle normally leaves part of its grain unfilled as if to anticipate some level of loss (Morrill, 1997). Numerous parasitoids, predators and pathogens present in most rice ecosystems tend to keep these potential pests at low densities (Shepard and Ooi, 1991; Barrion and Litsinger, 1994; Loevinsohn, 1994; Ooi and Shepard, 1994; Matteson, 2000).

Thus, under most situations where natural enemies are conserved, little yield loss is expected from typical levels of insect pests. Up until recently, insecticide applications for early defoliators, dead-hearts and white heads often led to lower natural enemy populations allowing the secondary pest, rice brown planthopper (*Nilaparvata lugens*), to flare up in massive outbreaks (Rombach and Gallagher, 1994). Work by Kenmore et al (1984) and Ooi (1988) clearly showed the secondary pest status of brown planthoppers. Although resistant varieties continue to be released for brown planthopper, the highly migratory sexual populations were found to have high levels of phenotypic variation and be highly adaptable to new varieties. Although wrongly proposed to be 'biotypes', it was found that any population held significant numbers of individuals able to develop on any gene for resistance (Claridge et al, 1982; Sogawa et al, 1984; Gallagher et al, 1994). Huge outbreaks have not reoccurred in areas where pesticide use has dropped due either to changes in policy regulating pesticides in rice or due to educational activities (Box 9.2).

A few minor pests are predictable problems and therefore should be considered for preventive action with natural enemies, resistant varieties, or specific sampling and control. These include black bug (*Scotinophara* spp.), gall midge (*Orseolia oryzae*), and rice hispa (*Dicladispa* spp.) which are consistently found in certain regions; thrips (*Stenchaetothrips biformis*), whereas drought causes leaf-curling that provides them a habitat; armyworms (*Mythimna* spp. and *Spodotera* spp.) in post-drought areas that are attracted by high levels of mobilized nitrogen in the rice plant and panicle cutting armyworms cause extreme damage.

Green leafhoppers (*Nephotettix* spp.) are important vectors of tungro (see below) but by themselves rarely cause yield loss. White-backed planthoppers (*Sogatella* spp.) are closely related to brown planthoppers in terms of population

Box 9.2 *Predators of BPH: hunting spiders*

Predators are the most important natural enemies of BPH. Together with parasitoids and insect pathogens they keep populations of BPH down. An important group of predators commonly found in rice fields is the spiders. Of particular importance are hunting spiders, especially *Lycosa pseudoannulata*. This is often found near the water level, the same area where BPH feed. A lycosid is known to feed on as many as 20 BPH per day. Its voracious appetite makes it a very important natural enemy of BPH. However, there are often questions asked about this predator.

A common one is: What will the spider feed on in the absence of BPH? Like other spiders, *Lycosa* and *Oxyopes* do not depend entirely on BPH for its food. There are many flies in the field that provide the bulk of the food for spiders. Studies in Indonesia have shown the importance of 'neutrals' in supporting a large population of predators in the rice fields. Spiders are found in rice fields before planting and they survive on these 'neutrals'. During the dry season, rice field spiders are known to hide in crevices or in grasses around the field. Like all predators, spiders are very susceptible to insecticides and so sprays or granular applications into the water will destroy these beneficial arthropods, thus allowing BPH to multiply to large numbers.

dynamics and are not usually a major yield-reducing pest. Rice water weevil (*Lissorhoptrus oryzophilus*) introduced from the Caribbean area in North America and North-East Asia is a problem pest requiring intensive sampling (Way et al, 1991) that deserves greater research on its natural enemies. In upland ecosystems, white grub species and population dynamics are not well studied and are difficult to manage. Way et al (1991) provide an overview of insect pest damage dynamics, while Dale (1994) gives an overview of rice insect pest biology.

Diseases

The need to grow more rice under increasingly intensive situations leads to conditions that favour diseases. High planting density, heavy inputs of nitrogen and soil fertility imbalances result in luxuriant crop growth conducive to pathogen invasion and reproduction. This is made worse by genetic uniformity of crop stand that allows unrestricted spread of the disease from one plant to another, together with continuous year-round cropping that allows carry over of the pathogen to succeeding seasons. Reverting to the less intense, low yield agriculture of the past may be out of the question, but a thorough understanding of the ecological conditions associated with the outbreak of specific diseases may lead to sustainable forms of intensification. We briefly describe the specifics for three major diseases of rice, namely, rice blast, sheath blight and rice tungro disease.

Blast (*Pyricularia grisea, Magnaporthe grisea*) occurs throughout the rice world but is usually a problem in areas with a cool, wet climate. It is a recognized problem in upland ecosystems with low-input use and low yield potential, as well as in irrigated ecosystem with high input use and high yield potential (Teng, 1994). Fertilizers and high planting density are known to exacerbate the severity of infection. Plant resistance is widely used to control the disease, but varieties often need to be replaced after a few seasons because pathogens quickly adapt and overcome the varietal resistance. Recent work by IRRI and the Yunnan Agricultural University demonstrated that the disease can be managed effectively through varietal mixtures (Zhu et al, 2000; see Box 9.3).

Sheath blight (*Rhizoctonia solani*) is a problem during warm and humid periods and is also aggravated by dense planting and nitrogen inputs above 100kg/ha^{-1}. No crop plant resistance is known for sheath blight. A number of bacteria (*Pseudomonas* and *Bacillus*) isolated from the rice ecosystem are known to be antagonistic to the pathogen. Foliar application of antagonistic bacteria at maximum tillering stage appeared to effect a progressive reduction of disease in the field over several seasons (Du et al, 2001). Incorporation of straw and other organic matter, with its effect on soil fertility, pH, and possibly on beneficial microorganisms may reduce sheath blight incidence in the long term.

Rice tungro disease, caused by a complex of two viruses transmitted by the green leafhopper (*Nepthettix virescen*), is a destructive disease in some intensively cultivated areas in Asia where planting dates are asynchronous (Chancellor et al, 1999). Overlapping crop seasons provide a continuous availability of host that

Box 9.3 *Diversity defeats disease*

Glutinous rice is highly valued in Yunnan, China, but like many varieties that have been 'defeated' by rice blast, it cannot be grown profitably without multiple foliar applications of fungicide. Rice farmers, guided by a team of experts from IRRI and Yunnan Agricultural University, have successfully controlled rice blast simply by interplanting one row of a susceptible glutinous variety every four or six rows of the more resistant commercial variety. This simple increase in diversity led to a drastic reduction of rice blast (94 per cent) and increase in yield (89 per cent) of the susceptible variety. The mixed population also produced 0.5–0.9 tonnes more rice per ha than their corresponding monocultures, indicating high ecological efficiency. By the year 2001, this practice has spread in over 100,000ha of rice in Yunnan, and is being tried by other provinces.

Varietal diversity creates an entirely different condition that affects host pathogen interaction. To begin with, a more disease-resistant crop, interplanted with a susceptible crop, can act as a physical barrier to the spread of disease spores. Second, with more than one crop variety, there would also be a more diverse array of pathogen population, possibly resulting in induced resistance and a complex interaction that prevents the dominance by a single virulent strain of the pathogen. Finally, interplanting changes the microclimate, which may be less favourable to the pathogen.

enables year round survival of the virus and the vector. Controlling the vector population with insecticide does not always result in tungro control. Synchronous planting effectively puts the disease at manageable levels. When and where planting synchrony is not possible, resistant varieties are recommended. In addition to varieties with a certain degree of resistance to the vector, varieties highly resistant to the virus itself became available recently. Farmers should also employ crop or varietal rotation, and rogue intensively.

Fungicidal control of blast and sheath blight is increasing in many intensified rice areas. It is extremely important that these fungicides be carefully screened not only for efficacy as fungicides but also for their impact on natural enemies in the rice ecosystem. One example is the release of iprobenfos as a fungicide for blast control. Iprobenfos is an organophosphate that was originally developed for brown planthopper control and is highly toxic to natural enemies. Its use in the rice ecosystem is likely to cause ecological destabilization and consequent outbreaks of brown planthopper. Fungicides should also be carefully screened for their impact on fish, both to avoid environmental damage in aquatic systems and to avoid damage to rice–fish production.

In general, clean and high quality seed with resistance to locally known diseases is the first step in rice IPM for diseases. An appropriate diversification strategy (varietal mixture, varietal rotation, varietal deployment, crop rotation) should counter the capacity of pathogens to adapt quickly to the resistance of the host. Management of organic matter has to be geared not only towards achieving balanced fertility but also in enhancing the population of beneficial microorganisms.

Farmers in Korea who face heavy disease pressure can learn to predict potential outbreaks using educational activities that combine various weather and agronomic input parameters with disease outcomes. Computer-based models are also being commercially sold to predict disease potential based on meteorological monitoring. With increasing nitrogen applications, however, greater disease incidence can also be expected.

Weeds

The origin of puddling for lowland rice cultivation is thought to have been invented to create an anaerobic environment that effectively kills several weeds including weedy and red rice. In most IPM programmes for lowland rice, weed management has therefore been closely considered part of agronomic practices during puddling and later during aeration of the soil with cultivators. At least two hand weedings are necessary in most crops, and considered in many countries economically viable due to low labour cost or community obligations to the land-less, who are then allowed to participate in the harvest. With rising labour costs, decreasing labour availability and more effective herbicides, this situation is rapidly changing to one of using one or two applications of pre- or post-emergence herbicides. As in the case of fungicides, it is critical that these herbicides do not upset natural enemies, fish or other beneficial/non-target organisms in the aquatic ecosystem including microorganisms (see Figure 9.1). In the case of upland rice, similar changes are rapidly occurring although better dry land cultivators are already being developed for inter-row cultivation as an alternative to herbicides.

Non-herbicide but low labour weed management methods are also emerging from the organic agriculture sector. The International Association of Rice Duck Farming in Asia supports research and exchanges among mostly organic farmers. In rice–duck farming, a special breed of duck is allowed to walk through the field looking for food that is either broadcast or naturally occurring, and the action of walking up and down the rows is sufficient to control most weeds. In Thailand, mungbean and rice are broadcast together with some straw covering in rainfed rice fields. When the rains come, both crops germinate. If there is abundant rain, the mungbean will eventually die and become part of the mulch, but if the rain is insufficient for the rice then the mungbean will be harvested.

No-till, no-herbicide combined with ground cover from winter barley straw or Chinese milky-vetch is being used in South Korea in both conventional and organic systems. Organic farmers in California use a water management system in which there is a period of deep (30cm) flooding followed by complete drying – the rice can take the changes but young weeds cannot. A widely adopted method in Central Thailand involves growing rice from ratoons. After harvest the stubble is covered with straw and then irrigated which allows the rice plant to emerge. This method not only controls weeds effectively but also increases organic matter and requires no tilling.

However, for the majority of rice cultivation, labour saving often means moving towards direct seeded rice and thus more weed problems. Red rice (weedy off-type of rice) is already the key pest in most of the Latin American direct seeded rice production areas. It seems clear that more direct seeding will lead to more herbicide use in rice production. Yet herbicide resistance is also sure to eventually emerge and there are obvious health and environmental costs associated with some herbicides. Thus it is important that IPM for rice weeds be improved and considered in the broadest terms (e.g. promoting modern rice varieties that are red in colour among consumers may be part of the solution to red rice problems). Crop rotations are feasible in only some areas, while simple line sowers or tractor sowing in rows combined with manual or tractor cultivation may provide some solutions for lowland and upland rice.

Genetically modified herbicide-resistant rice will eventually be on the market, but Asian consumer preference may not favour these varieties. However, the resulting increase in herbicide use could have obvious adverse effects on the aquatic systems that are associated with most rice production. In addition, a major problem of herbicide resistant rice is the possibility of the transfer of gene resistance to weedy rice, though such transfers would not occur to wild grass species. Use of herbicide resistant rice in monocropping could also create, in the long term, serious problems of glyphosate resistance in weed species previously susceptible to the herbicide. The ecosystem level interactions of herbicide resistant rice will need careful assessment prior to their use.

Community pests

Insects, diseases (with the exception of tungro virus) and weeds in rice ecosystems are generally managed with decisions on individual farms or plots. However, some pests, particularly rats, snails and birds, require community-level planning and action. Management of these pests requires facilitation of community organizations not generally supported by extension services with the possible exception of some multi-purpose cooperatives and water-user associations.

Numerous species of rats occur in rice fields and can cause considerable damage. Rats migrate from permanent habitats to rice fields as food supply changes throughout a yearly cycle, with rice plants most preferred after the panicles have emerged. Some natural enemies of rats, particularly snakes, are harmed by pesticides and often killed by farmers, thus resulting in more rats. The most effective management strategies are to ensure baits are appropriate to the species present, and then carry out continuous trapping along feeding routes, fumigation or digging of rat holes, and establishing early season bait stations using second generation anticoagulant baits (although more toxic zinc phosphide and repackaged and unlabelled aldicarb is still commonly seen but strongly discouraged in most countries due to the deaths of children and small livestock). Community programmes can include educational activities on rat biology and behaviour (Buckle, 1988), and an emphasis on action during the early season vegetative stage is considered the key to rat management (Buckle and Smith, 1994; Leung et al, 1999). An innovative owl habitat programme in Malaysia has been successful in increasing owl populations to control rats in rice and plantation crops.

The Golden apple snail, *Pomacea canaliculata*, was originally introduced to rice growing areas as an income generating activity for a caviar look-alike given its brightly pink coloured egg clusters. It has since become widespread from Japan to Indonesia and is now one of the most damaging pests of rice. It was introduced without appropriate tests in any country even though it was on the quarantine lists of several countries. The snail feeds on vegetation in aquatic environments, including newly transplanted rice seedlings up to about 25 days old when the stems become too hard. With no natural enemies and having highly mobile early stages that flow with irrigation water, the golden snail spreads rapidly. Pesticides are often used before transplanting or direct seeding, mainly highly toxic products such as endosulfan, organo-tin products and metaldehyde. These products have serious health implications and also cause the death of potential fish predators and natural enemies early in the season (Halwart, 1994). The use of bamboo screens as inlets to fields to inhibit snail movement is reported as the first line of snail defence. Draining fields that have several shallow ditches where the snails will congregate allows for faster collection or eases the herding of ducks into fields to eat the snails. In Vietnam, snails are reported to be collected, chopped, cooked and used as fish food to such an extent that they are now a declining problem.

Birds can be very damaging especially when occurring in large flocks. The Red-billed Quelea, *Quelea quelea*, in sub-Saharan Africa and various species in Asia are known as consistent problems in rice ecosystems. In most Asian countries and in Chad, netting is used to trap large numbers of birds for sale as food. Mass nest destruction is also possible for some species. In Asia, these methods have effectively reduced pest bird populations to very low numbers. In Africa, the capture method may bring benefits to local people in terms of income or a good protein addition to the diet, but the impact on pest bird populations has been small. During the ripening period in North-East Asia, some fields are protected by being covered with bird nets. Reflective ribbons or used video or cassette tape are widely used to scare birds in Asia. Sound cannons and owl or hawk look-alikes are also used in many countries, though some birds become quickly habituated to mechanical devices. Use of poisoned baits and the destruction of bird nesting habitat are discouraged both because they are seldom effective and also because of the potential negative effect on non-target species in adjacent aquatic environments.

Does IPM Work for Rice Farmers?

Although there is a large amount of grey literature (see www.communityipm.org) related to rice IPM impact among farmers, there is little peer-reviewed published data. This is in part a reflection of the financial and technical difficulty of conducting these studies. Longitudinal studies in agriculture are notoriously difficult due to seasonal changes. Latitudinal studies (comparisons across sites) are also difficult due to the fact that finding an identical IPM and non-IPM control is rarely possible given the diversity of ecological and social conditions. Nonetheless, such evidence as does exist indicates considerable benefits for rice IPM farmers.

The first, and perhaps strongest indicator, is the greatly reduced incidence of brown planthopper. Wide area outbreaks accompanied with massive losses have no longer been experienced during the past 15 years since IPM programmes have become widely implemented in both policy and field training. In most cases, changes in policy involved the removal of pesticide subsidies, restrictions on outbreak-causing pesticides, and investment in biological research and educational programmes for decision makers, extension workers and farmers. These policy changes most often came about as a result of successful small-scale field trials. The FAO Inter-Country Programme for Rice IPM in South and South-East Asia, headed by Peter Kenmore, brought policy makers in contact with researchers and farmers who could explain from their own experience the ecological basis of farming with IPM methods. The banning of 57 pesticides and removal of pesticide subsidies known to cause brown planthopper outbreaks in 1987 in Indonesia by the former President Suharto came about after cabinet officials were brought into a dialogue with both senior Indonesian and IRRI scientists and farmer groups who had shown the outbreak effects of the pesticides and their ability to produce high rice yields without these pesticides (Eveleens, 2004).

The second indication comes from case study literature (FAO, 1998). Table 9.1 gives a typical result found across hundreds of communities surveyed in rice IPM programmes. This shows the key changes in practices, especially the common outcome of investing less in pesticides and more in fertilizers (including P and K). Other large-scale studies provide similar data, although a recent study in Vietnam notes an increase in the use of fungicides. The authors have noted that with higher levels of fertilizers (as would be found in Vietnam) such increases in fungicide are predictable. This data also reveal the multidisciplinary aspect of rice IPM in that it encourages farmers to look beyond the pest complex into the multiple parameters for achieving a profitable high yielding crop.

Getting IPM into the Hands of Farmers

'IPM is not for farmers but is by farmers' is often noted in IPM programmes. Getting IPM into the hands of farmers, however, is not always easy. Several methods have been developed with various levels of information and completeness. Most agricultural extension services now recognize the importance of natural enemies and are quick to point out the need to conserve them, even though their co-promotion of various insecticides, fungicides and herbicides is at odds with this apparent awareness of natural enemies. Work by Heong and others from the Rice IPM Network (Heong et al, 1998; Heong and Escalada, 1999; Huan et al, 1999)

has developed interesting radio messages to get the word out on a large scale that early spraying of insecticides during the first 40 days of the crop is not only unnecessary but increases the risk of higher pest populations later in the crop. The radio messages are accompanied by field-based plant compensation participatory research groups in many cases (Heong and Escalada, 1998). This programme has been effective in increasing awareness of the adverse effects of insecticides on natural enemies and the role of plant compensation in recovering without yield loss from early season pest damage and has resulted in reduced early insecticide sprays.

Study groups of various types are now common in many rice systems. They are reported from organic agriculture, rice–duck groups, Australian rice farmer associations and many others. The FAO Community IPM Programme in Asia (Matteson et al, 1994) has promoted study groups now called 'Farmer Field Schools' under which structured learning exercises in fields ('schools without walls') are used to study both ecosystem level dynamics transferable to other crops (predation, parasitism, plant compensation) as well as specific rice IPM methods. Already, more than 1.5 million farmers have graduated from one or more season-long Field Schools in Asia over the past decade with good cost-effectiveness as an extension methodology (Ooi et al, 2001).

Community-based study groups, study circles, field schools and other approaches are now being integrated with wider community-based organizations, such as IPM clubs, water-user groups, women's organizations and local farmer unions (Pretty and Ward, 2001). With the large-scale training and visit style extension programmes generally being phased out in most countries, it will be necessary for local communities to become organized in ways in which they can increasingly cover their own costs for experts. Primary school programmes on IPM are also emerging in Thailand, Cambodia, Philippines and other countries as part of environmental education curriculum related to Asian rice-culture. Such programmes as Farmer Field Schools in many countries or Landcare in Australia and the Philippines are providing innovative models in community-based study and action.

The future of IPM in rice in Asia, if not globally, should see the phasing out of all Class Ia, Ib and II products, while phasing in production methods that allow for whole ecosystem approaches. Organic pest management (OPM) alongside the rapid expansion of certified organic rice production is certainly an area fertile for research and training in addition to modernized IPM approaches.

Vegetable Production in Tropical Asia

Vegetables are an important part of the diet, adding valuable nutrients that would otherwise be insufficiently available in staples such as rice or maize. New production areas are continuously being opened up, sometimes at the expense of rice land, to meet the demands for vegetables, particularly crucifers, carrots, potatoes, tomatoes and beans. Many vegetable crops perform best under cool temperatures found in higher altitudes, but, increasingly, vegetable production is expanding into the lowlands with the release of new heat-tolerant varieties mainly bred in Asia. But the achievement of good yields, particularly in the warm humid lowlands, is often constrained by pests and diseases. Most vegetables are heavily sprayed and in many places poor horticultural practices exacerbate these crop production constraints. In general, a lack of skills among vegetable producers and limited or no access to sources of information on new and ecologically sound crop production practices provide a clear rationale for why much of intensified vegetable production in Asia is currently facing serious problems.

Problems Associated with the Indiscriminate use of Synthetic Pesticides

The indiscriminate use of synthetic pesticides in intensified vegetable production in tropical Asia is a serious problem (Shepard et al, 2001). Pest problems in tropical vegetable production occur frequently and are often acute. Yields are highly

Table 9.2 *Average number of pesticide applications per season for selected vegetable crops in Cambodia*

variable while farm gate prices vary considerably on both a daily and seasonal basis. Compared with rice, the riskiness of vegetable production provides a stimulus for farmers to rely on preventive pesticide applications. For some vegetable crops the average frequency of application of chemical pesticides is 10–20 times per season (see Table 9.2), with up to 80 applications per season for *brinjal* (eggplant) production in parts of South Asia (e.g. in Bangladesh).

The application of cocktails of pesticides by vegetable farmers is also a common phenomenon, particularly in Cambodia and Indonesia. Farmers mix insecticides with fungicides and herbicides in an effort to make them more effective. These cocktails commonly include banned or restricted, and often highly toxic, insecticides such as DDT, endosulfan, chlordane, sodium cyanide, methyl parathion, mevinphos, methamidophos or monocrotophos.

A recent survey among 332 vegetable producers in Cambodia indicated that 55 per cent of farmers interviewed were using WHO Class Ia pesticides. This figure increases by another 18 per cent when farmers who are using Class Ib pesticides are included. Thus, an alarming 73 per cent of interviewed farmers were frequently handling highly and extremely toxic pesticides under conditions that are far from those that can possibly be considered safe (see Table 9.3). The health hazards to farmers and their families are serious (Murphy et al, 1999; Sodavy et al, 2000).

In Cambodia and Laos, labelling of pesticide products is often inappropriate as labels are usually in foreign languages (Thai, Vietnamese). This situation is aggravated by high illiteracy rates in the rural population. Original products are often repackaged and contain no label at all (EJF, 2001). For example, a recent study conducted in Cambodia revealed that only 8 of 77 pesticide traders said they could read foreign labels on pesticides they sold, whilst 97.5 per cent of the pesticides were labelled in a foreign language (CEDAC, 2000). The extensive use of synthetic pesticides results in a range of unsustainable production practices arising from undesirable externalities. The frequent applications of pesticides most often causes resurgence of pest populations because of the destruction of natural enemies. Resistance of target pests against pesticides has become a serious problem for many important vegetable pest problems, such as diamond back moth (*Plutella xylostella*) on crucifers and fruit and shoot borer (*Leucinodes orbonalis*) on eggplants.

However, greater awareness among consumers in urban communities of the dangers of pesticide residues on vegetables has created a growing demand for vegetables free of residues. Governments in many developed Asian countries have now established maximum residue levels (MRL) regulations for pesticides on imported vegetables. Clearly, the consequences of international trade restrictions related to residues of toxic pesticides on vegetable produce can no longer be ignored. Nonetheless, vegetable production in tropical and subtropical Asia remains in a 'crisis phase' (Lim and Di, 1989; Shepard and Shepard, 1997), requiring urgent attention to safeguard the production of healthy food and producers' livelihoods across Asia.

Vegetable IPM: Ecosystem Considerations and the Need for 'Informed Intervention'

What is it that drives the frequent use of pesticides in intensified vegetable production in most of Asia? The main factors seem to be the high risk of crop losses, the acute occurrence of serious crop pests, and the heavy promotion of pesticide use by the private sector. In addition, the low level of ecological literacy and wider low level of education of farmers, particularly in a country like war-ravaged Cambodia, further explains the rampant use of pesticides. However, it is important to understand that there are some major differences between the need for human intervention in ecosystem management when comparing vegetables to rice in tropical Asia.

While many locally consumed vegetables are native to tropical Asia, most vegetables produced in Asia for local consumption and for market supply are exotics. Many popular cash crops such as tomatoes, crucifers, potatoes were relatively recently introduced to Asia from temperate regions. Similarly, many important pest and disease problems are exotic, such as the diamond back moth, which was introduced from Europe into Asia without its naturally existing complex of natural enemies. If not swiftly and adequately managed, crop protection problems can lead to serious cosmetic damage and total crop failure. Vegetable ecosystems are much less stable compared with paddy rice ecosystems

Any rice FFS alumni farmer would be able to explain and demonstrate in their field that there are several highly effective predators and/or parasitoids indigenously available as integral components of a well-functioning rice ecosystem. As a result, pest populations are well regulated and rarely reach critically damaging levels. Management interventions are therefore rarely needed. In fact, human intervention with applications of pesticides causes more problems than it solves. The basic message that IPM Farmer Field Schools spread focuses on ensuring that farmers do not intervene when pest problems occur, and rather let nature play out its well-regulated population dynamic games. The IPM management strategy to be employed in Asian rice production can thus be characterized with 'informed non-intervention'.

But the situation is very different in vegetable ecosystems in tropical Asia, as these are designed to prevent and manage pest and disease problems from causing serious crop loss. The crop protection strategy therefore employed in intensified tropical vegetable production is based on informed (and proactive and preventive) intervention (Whitten and Ketelaar, 2003).

Making Vegetable IPM Work: The Need for Farmers to Become IPM Experts

With the urgent need to address problems associated with the indiscriminate use of pesticides, the FAO Inter-Country Programme for Vegetable IPM in South and South-East Asia has carried out applied research, extension and farmer education activities to promote and support IPM in vegetables. Based on impact assessment of farmer training work conducted by this FAO Programme and its associated National IPM Programmes in a variety of crops in several Asian countries, IPM trained vegetable farmers can now avoid excessive and inappropriate use of pesticides (Larsen, 2001; Lim and Ooi, 2003).

Farmers who undergo season-long discovery-based training in Farmer Field Schools become ecologically literate, and so can understand much better how ecosystems function and what is the likely impact of their management decisions. By being better able to identify field problems and assess their potential impact on yields, farmers can considerably reduce the use of pesticides in vegetable production and limit any remaining applications to those situations where human intervention is necessary. As a result of FFS training, farmers can also make better decisions on which pesticides to purchase, how and when to apply them, and how to avoid cocktail formulations.

These IPM trained farmers are then better placed to access new information and to adapt and adopt novel options that reduce further dependency on pesticides. The potential for better understanding and improved access of farmers to biocontrol interventions, such as the employment of viral and fungal pathogens and the introduction of parasitoids for pest management, is considerable. But it requires proactive action from a range of different stakeholders (research, private sector, extension workers and farmers) so as to ensure that functional biocontrol can reach its full potential. This would further assist the process of eliminating toxic products from vegetable production.

In Cambodia, the National IPM Programme, with FAO support, is currently implementing a FFS-based farmer training programme in several major vegetable growing areas in the country. Farmers who have undergone training are now running training for other farmers and are actively experimenting with growing crops with lower inputs of pesticides. When interventions are indeed needed, farmers now prefer to resort to biocontrol, using the biopesticide, *Bacillus thuringiensis*, which has no adverse effects on farmers' and consumers' health.

Local NGOs, such as Srer Khmer, are actively supporting a self-sustained and multiple season IPM learning process and are facilitating the mobilization of IPM farmer groups and their associations. IPM farmer clubs are also increasingly becoming interested in embarking on the production of organic vegetables for the local niche markets. With the active support from the Government and NGOs, formal education efforts are underway to give school children access to ecosystem education, using the discovery-based learning methodologies employed in the FFS for adults. The hope is that this will lead to greater ecological literacy among Cambodia's youth and future farmers.

Future Needs in Rice and Vegetable IPM

There is still much room for improvement for IPM. Indeed, the ecological view of rice and vegetables presented here must be given greater support by international and national scientists and policy makers to widen economic and ecosystems benefits already being realized by some farmers. A new CD-ROM produced by IRRI is beginning to bring together basic rice information in an accessible format, while the World Vegetable Centre in Taiwan has developed a web-based study programme. Both programmes could be helpful in training extension staff but still remain distant from farmers. Major other challenges remain. Post-harvest pests are still a problem and deserve greater research on non-toxic management methods, and environmentally friendly methods of controls for all types of pests, especially weeds and fungal pathogens, are required to reduce the pressure on the natural resources.

Some countries are calling for major changes. South Korea has banned pesticide use in Seoul's watersheds and is promoting organic agricultural investments to ensure both clean water and high levels of production. Other communities are moving away from grain maximization to diversification such as rice–fish–vegetable culture as a response. This is expected to increase as demand for more profitable non-grain products increases and nitrogen use is reduced to lower environmental impacts and incidence of expensive-to-control fungal pathogens. However, IPM development is required in more countries. These programmes should ensure that educational systems (both formal and non-formal) are responding to the future needs of reducing the environmental impact of agriculture while improving yields. IPM is clearly a major aspect of this education.

There is a need to phase in new plant protection methods and products including subsidizing commercialization of locally produced products such as pheromones, attractants, natural enemies, pest-exclusion netting (for insects and birds), high-quality seed, improved disease resistance and balanced soil fertility products. High foreign exchange costs for imported pesticides and increasing consumer awareness of the social costs arising from pesticides and inorganic fertilizers can be expected to drive rice IPM system development. The trend will be towards lower impact and local production of environmentally friendly pest management. A significant redefinition of IPM to exclude Class I and most Class II products could be a most important step to revitalize private sector, research and extension IPM activities.

The Farm as Natural Habitat

Dana L. Jackson

'We should be having our summer board meeting on a farm. It's really beautiful at my place now.' When Dan French brought this up at the annual meeting of the Land Stewardship Project's board of directors, everyone nodded in agreement. Why didn't we think about scheduling the meeting there? I had spent a few days at the French farm several summers ago, sitting under a tent listening to instructors in the holistic management course held there and looking at Muriel's flower garden and the black-and-white dairy cows in the pasture beyond. A light breeze brought us the fragrance of green alfalfa from the barn where Dan's son was unloading bales. The class walked down to the creek, where we talked about the water cycle and how to judge water quality by observing the kinds of insects and fish in the water. The gravel on the creek bottom sparkled in the clear water. There was a flurry of birds and birdsong in the taller grass of a pasture section that hadn't been grazed for awhile.

When you drive up to the French farm, it looks like an interesting place, with its barns and outbuildings, vegetable and flower gardens, and shady picnic area. It doesn't look like those farmsteads one often sees in the Corn Belt, where the house and a machinery shed or two seem to just stick up out of a corn field, as if the owners had planted every inch they could on the place. Actually, if you drive on Interstate 35 between Saint Paul and Des Moines, you do not even see many houses. The landscape in July seems to be covered just with corn, a seemingly endless monotony of green stalks broken occasionally by shorter bushy soybeans.

It is hard to imagine what it must have looked like when Europeans first settled the Midwest, when it was a wilderness covered with prairie, forests, clear streams, and herds of buffalo. Too quickly it became dominated by agricultural uses interrupted by a few patches of prairie or woods around lakes or rivers that harboured remnants of natural habitat. Some prairie plants survived in pastures and meadows until they were replaced by fields of corn and soybeans in the last part of the 20th century. Then animals were moved into barns and feedlots, fences came down, and habitat edges disappeared. It only took about 150 years to reduce biological diversity on this landscape to a numbing sameness.

It is no surprise that people passionate about wildlife and the preservation of natural habitats have concentrated on protecting other places, those dramatic expanses of land where more of the original landscape remains, such as the Boundary Waters Canoe Area in northern Minnesota, the rugged mountains of Colorado and Montana, and roadless areas in Alaska. Such conservationists have accepted the agricultural Midwest, especially the Corn Belt, as a sacrifice area, like an open pit iron mine, or an oil field, where we mine the rich soil and create toxic wastes to extract basic raw materials. But the environmental impacts of this kind of mining are not confined to farming country. No nature preserves within its watersheds or wildlife area downstream on the Mississippi River can be adequately protected from farming practices that simplify ecosystems to a few manageable species and replace ecosystem services with industrial processes.

People who live in rural areas or urban residents who drive through them may not know that they are seeing a biologically impoverished landscape, because they have no knowledge of its diversity before modern agriculture. Others may know or imagine what the land looked like with different kinds of crops, meadows and livestock in pastures, but they accept its simplification because they are convinced that the main trends in agriculture cannot be overcome. Agribusiness has successfully persuaded farmers, politicians, civic leaders and even conservationists to believe that agricultural modernization leads to specialization and industrialization, and that financially viable alternatives are unavailable even though such modernization reduces the rural quality of life and harms the environment.

In this chapter, I will introduce an alternative vision for agriculture that defies the trends considered inevitable. It is a vision inspired by Aldo Leopold's writing that farming and natural areas should be interspersed, not separated, and by the farmer-members of the Land Stewardship Project, whose ways of managing farms have created a natural habitat for them, for their crops and livestock, and for the native plants and animals of the area. I will also describe two sustainable farming practices that currently are improving biological diversity on rural landscapes and showing the real possibility of this vision. Let us look at the practices of mainstream industrial farming that render the countryside an ecological sacrifice zone.

Rural Lands as Industrial Zones

The loss of biological diversity was not the only environmental consequence of creating the Corn Belt. Soil erosion, depletion of water resources, contamination of groundwater and surface water from fertilizers and pesticides (Soule and Piper, 1991), and a steady silt load in rivers are some of the consequences of so much tilled land. The sediment load in the Minnesota River at Mankato is equal to a ten-ton dump truck load moving by approximately every five and a half minutes (Minnesota Pollution Control Agency, 1994).

The most serious environmental consequences are yet to come because of the growing consolidation in the livestock industry fuelled by the abundance of cheap corn and soybeans. Each year an increasing number of poultry and hogs raised in the Corn Belt are not dispersed across the countryside on independent farms but are instead concentrated in large operations. Hundreds of thousands of chickens and tens of thousands of hogs are confined in buildings, creating huge quantities of manure that pose serious environmental risks to ground and surface water. Hydrogen sulfide fumes in the stench emitted from the operations have sickened neighbours. People do not want to live close to these hog factories or visit relatives close to hog factories. The once rich prairies that became bucolic communities are now industrial zones, suitable for 'neither man nor beast'.

Dairy farmers also feed the bounteous harvest of the Corn Belt to cattle confined in barns and milked three times a day. Dairy operations with 1000 to 2000 cows are replacing traditional family-sized farms with 100 or fewer cows. They manage large quantities of manure the same way as hog factories do and present the same risks to water quality. Travellers through Wisconsin's wooded hill lands graced with small dairy farms in the valleys may be unaware of how this landscape will change if consolidation continues in the dairy industry and four dairy farmers go out of business each day in the state as they did between 1992 and 1997 (USDA, 1997). Where large-scale dairies replace small ones, the scenes of black-and-white cows grazing on green pastures and moving in line to and from red barns are being replaced by fields of corn and soybeans with nary a cow in sight.

Factory livestock operations have popped up like mushrooms across the entire Midwest and Great Plains. They have also grown rapidly in southern states and are emerging everywhere state laws are weak and local communities naively believe the industry's forecasts for economic development. California led the way with its 1000 cow dairies and became the leading milk producer in the country; as a result, departments of agriculture in traditional dairy states are promoting California-style dairying. Agricultural economists encourage farmers to expand their operations to be efficient and convince them that all dairy cows and pigs, like poultry, are going to be raised in large-scale confinement operations in the future. It is inevitable.

This mantra of 'it's inevitable' is happily chanted by the corporate processors of pork that benefit from large supplies of cheap hogs, and, sadly, this mantra is repeated by many farmers. Some of them borrowed heavily to expand and build hog confinement buildings, and when pork prices plunged to an historic low in the 1990s, they went bankrupt. The huge packing plants that encouraged industrial production prospered and consolidated into even larger corporations through mergers (Heffernan, 1999).

We are seeing rural landscapes all across the US changing for the worse because farmers believe that further industrialization in livestock agriculture is inevitable and that they must 'get big or get out'. Some farmers incur staggering debt to increase the size of their operations, some form family corporations to share the costs of expansion, others invest in new buildings and technology to become contract producers for corporations, and some just leave farming and sell out to neighbours who want to expand. A house in the country isn't so romantic any more, because it might very well be within odour range of one of these hog expansions.

Hay meadows and pastures with wildflowers and grassland birds are few and far between, and many streams running through fields have been cleared of trees and wildlife. If a family cannot earn a living on the land, and it is not a beautiful or healthful place to live, they might as well move to town. The land serves utilitarian purposes only, sacrificing natural values that once made it a home, not only for humans, but also for all kinds of creatures.

The disappearance of diversity in farming country has occurred steadily, mostly without notice or comment. Politicians and policy makers, the US Department of Agriculture, land grant universities, and many farmers and rural people accept the loss of biological diversity on the land as a necessary cost of efficient high production. There is some nostalgia in older people for a favourite fishing or swimming hole on the creek of the farm on which they grew up, but farming is a business and you cannot be sentimental about it. Most travellers are not aware that many of the monotonous fields they see along the highways harboured wildlife in prairie pastures and hayfields as recently as the 1960s. They only know that if they want to see woods and prairies and wildlife, they must head for a publicly owned park or wildlife area where agriculture is not practised.

Aldo Leopold and a Different Vision for Agriculture

Aldo Leopold, the Midwest's most famous conservationist, disapproved of the separation of natural areas from farming. To him it did not make sense to protect forests in a special area and accept the absence of trees on agricultural land, when the farm was then left without the conservation benefit of erosion control and windbreaks. 'Doesn't conservation imply a certain interspersion of land uses, a certain pepper-and-salt pattern in the warp and woof of the land use fabric?' he asked (Leopold, 1991). Leopold believed that conservation efforts on certain parts of the land would fail if other parts were ruthlessly exploited. He wrote in the essay 'Round River':

> Conservation is a state of harmony between men and land. By land is meant all of the things on, over, or in the earth. Harmony with land is like harmony with a friend; you cannot cherish his right hand and chop off his left. That is to say, you cannot love game and hate predators; you cannot conserve the waters and waste the ranges; you cannot build the forest and mine the farm. The land is one organism. (Leopold, 1966)

Although Leopold knew that agriculture was becoming more industrialized and wrote about the dangers of a farm becoming a factory, he could not have imagined the enormous livestock factories in production today. The transformation of so many meadows, prairies and wetlands into corn, beans and hogs in Iowa, the state of his birth, and conversion of family-sized dairy farms into milk factories and corn fields in his adopted state of Wisconsin would astonish and grieve him. However, if someone told him about the zone of hypoxia in the Gulf of Mexico, 7000 square miles depleted of marine life because of excess nutrients flowing down the Mississippi River from the Corn Belt, I doubt if he would be surprised.

It is understandable that people accept these trends as the destiny of agriculture if they cannot clearly see alternatives. But there is an alternative – another trend – that could produce a landscape of farms which are natural habitats rather than ecological sacrifice areas.

A strong minority of modern farmers, like Dan and Muriel French, have not turned their farms into factories nor abandoned their chosen profession but are instead leading agriculture in an entirely different direction. Their creative initiatives to make farming more economically sound and environmentally friendly are producing benefits for them, for society at large and for the land. The trends of these models are toward independent farms supporting families and communities while restoring biological diversity and health to the land.

Using an ecological approach to management decisions, these farmers are restoring a relationship between farming and the natural world that improves the sustainability of both. This relationship makes the farm a natural habitat. It is a natural habitat for humans in that it is a healthful and aesthetic place to live and earn a living. The farm is a natural habitat for the crops and livestock because they are able to use ecosystem services for fertility and pest control rather than fossil fuel and man-made chemicals. And the farm is a natural habitat for native plants and animals, a refuge that encourages biological diversity along streams, in pastures and along uncultivated edges.

Farming Practices for Natural Habitat

Farmers themselves do not talk about turning their farms into natural habitats. It happens as a result of the way that they choose to farm. Many farmers became interested in changing their practices in the 1980s, particularly during a period of low prices, high production costs and minuscule profits. A number of newly formed farming organizations around the country helped them lower their use of purchased inputs, such as chemical fertilizer and pesticides, and develop more environmentally friendly practices. For example, the Land Stewardship Project (LSP) in Minnesota began to hold workshops and field days about the practice of *management intensive rotational grazing*. This involves dividing a pasture into sections or 'paddocks' with electric fences and allowing the animals to graze each area intensively for a short period of time before moving them on to another area. In conventional grazing, livestock roam freely in an open pasture, often overgrazing some areas and causing erosion.

Management intensive rotational grazing roughly mimics grazing patterns of migrating buffalo herds that preceded European settlement on the plains and prairies, but domestic livestock return to graze an area much sooner than did buffalo.

The length of time that animals graze a particular paddock usually depends upon the rate of recovery of the forage after grazing and its nutritional value, which requires farmers or ranchers to become attentive observers of their pastures and all that is growing there.

A group of farmers wanted to know how they could tell whether the switch to management intensive rotational grazing was making their farms more sustainable. In response, the Land Stewardship Project established a biological, social and financial monitoring project, conducting research on six diversified livestock and dairy farms that used management intensive rotational grazing. The project team that worked together for three years included university researchers and state agency staff in addition to the six farmers and LSP staff. To conduct biological monitoring, researchers helped the six farmers collect biological, physical and chemical soil quality data from 60 plots and make observations about pasture vegetative species and ground cover. They sampled wells and kept precipitation records. The farmers learned to survey their land for breeding birds, frogs and toads, and they helped fisheries scientists survey streams passing through four of the team farms and through one paired farm to analyse the effects of management intensive rotational grazing on stream banks and stream invertebrate and fish populations.

These farms were seen as natural habitats, not as ecological sacrifice areas. The farmers wanted to find out if the soil and the water quality in streams on their farms were improving, just as they wanted to know if their financial bottom lines were improving by cutting production costs. They were not accepting the 'inevitable', that they must get big or get out.

The farmers in the monitoring project, and many others who have been constituents of the Land Stewardship Project, practise holistic management, a decision making process based on goal setting, planning and monitoring. This process was developed by Allan Savory, who founded the Center for Holistic Resource Management in Albuquerque, New Mexico, in 1984. Land Stewardship Project staff taught many holistic management courses throughout the Upper Midwest. They developed a research project to monitor the effectiveness of management decisions made by the six farmers who had taken the course and were making the switch from conventional grazing to management intensive rotational grazing.

Holistic management contains four elements that distinguish it from conventional farm management and provide managers with strong incentives to make environmentally sound decisions. First, as part of the goal-setting process, it directs managers to develop a long-term vision for how they want the landscape to look far into the future. Second, the model teaches basic recognition of ecosystem processes that farms are dependent upon: the water cycle, the mineral cycle, plant succession and energy flow (Savory, 1998). Farmers strive to understand these processes and harmonize their farming practices with them. For example, farmers can rely on nitrogen fixation in legumes and the recycling of nutrients in manure to provide fertility for fields. Third, holistic management places a high value on biological diversity both in crop systems and in areas on the land not used for farming.

And last, practitioners consider the effect of any proposed action or choice of enterprise upon quality of life for the community as well as for themselves. They understand that their land is part of a larger whole and how they manage it will affect the landscape around them and the lives of people in the community. Holistic management has become an effective tool for those who want to be good stewards of the land and earn a living on it at the same time.

Though holistic management has been used on all kinds of farming operations, it was developed by Allan Savory in connection with rotational grazing. Farmers in the Upper Midwest often began using holistic management and management intensive rotational grazing approaches simultaneously. Cattle grazing on public lands in western states has been considered such a disaster by environmentalists that many have a negative view of grazing anywhere. However, at the landscape level in the Midwest and in parts of the Great Plains and the South management intensive rotational grazing provides visible environmental improvement in farming, especially where field crops have been converted to permanent pastures and livestock eat more grass than grain. Fewer acres of corn and soybeans also mean fewer applications of chemical pesticides, herbicides and fertilizer, which decreases the potential for contamination of surface and groundwater. When corn and soybeans are replaced by perennial grasses, there is less soil erosion (Cambardella and Elliot, 1992; Rayburn, 1993).

Dairy farmers have widely adapted management intensive rotational grazing. Between 1993 and 1997, the number of Wisconsin dairy farmers using variations of this grazing method increased by 60 per cent (ATFFI, 1996). Milk cows on most conventional dairy farms are confined in 'loafing barns' or corrals between milkings and are never allowed out to graze. On very large operations of 500–1500 or more cows, feed is brought to the cows and all of their manure is pumped out of manure pits or scraped and hauled out of the barns to be spread on fields. Conventional dairy farmers work hard to produce the corn and alfalfa to feed the dairy herd, and capital costs for equipment and barns are high. In contrast, grass-based dairy farmers usually move cattle daily but claim that their work load and costs of production are much less because the cattle walk around in the paddocks, get most of their own food, and disperse their own manure (ATFFI, 1996). With more feed produced in pastures, a farmer uses less machinery and fossil fuel (Rayburn, 1993). Some grass-based farmers 'don't have much iron', as they say, because they have sold most of the machinery they formerly needed for large fields of corn. With fewer acres planted for feed, they can share machinery with neighbours, employ custom harvesters to bring in their crops or even buy feed from other farmers. For these dairy farmers, management intensive rotational grazing is a farming practice that benefits them as much as it benefits the land and the water.

Poultry and hog farmers also use management intensive rotational grazing. Hogs can be put on pasture to graze, at least for part of their food, and spread their own manure in the grass. Hogs can spend most of their time outdoors and farrow in pastures. Farmers in the Upper Midwest often combine outdoor and indoor production systems by bringing hogs into open-ended metal hoop buildings covered with canvas for the winter. Hogs bed in deep straw or corn stalks, which composts with their manure, warming the hogs in the process and producing nearly composted, dry fertilizer for the fields when the barns are cleaned. Manure is not a toxic waste in management intensive rotational grazing or hoop house production systems, and the cost to the farmer of handling it and the public for regulating it is little or nothing. In fact, overall production costs are so much lower that farmers can make a profit as long as they have fair access to markets (Dansingburg and Gunnink, 1995) or sell cooperatively with other farmers or directly to consumers. If market prices are too low, farmers can use these hoop houses for other purposes, such as storing hay or machinery, which gives them a flexibility that producers trying to pay off the debt for a high-tech, single-use confinement facility do not have. Using management intensive rotational grazing and deep-bedded straw systems in hoop houses, farmers can take advantage of ecosystem services in providing animal feed and managing manure. These systems are efficient alternatives to the industrial production models for livestock and can compatibly exist alongside or as part of natural ecosystems.

The Benefits of Diversity

Diversified farms producing feed for their own livestock may rotate crops of alfalfa or other legumes, corn, soybeans and small grains such as barley or oats, in contrast to conventional cash grain farms that rotate only corn and soybeans or grow corn with no rotation. For example, Jaime DeRosier employs a complex rotation of hay, wheat, barley, vetch, flax, buckwheat, corn and soybeans on his large organic farm in north-western Minnesota (DeRosier, 1998). The Fred Kirschenmann farm in North Dakota rotates up to ten different grain or hay crops in three different rotations (Anonymous, 2000). In all parts of the country, farmers are also planting several different kinds of grasses and legumes in their pasture mixes, planting fields in strips of several crops, intercropping one species with another (such as field peas with small grains) and using cover crops between plantings of major crops. In California, orchards, vineyards and specialty crop farms have added cover crops and farmscape plantings to attract pollinators and other beneficial insects (CAFF, 2000).

The benefits of biodiversity in agriculture were effectively laid out in a report with that title by a task force of the Council for Agriculture Science and Technology, co-chaired by ecologist G. David Tilman and geneticist Donald N. Duvick (CAST, 1999). The report stresses the dependency of modern agriculture upon biological diversity and advocates greater attention to preserving diversity both in domesticated crops and livestock, and in the natural landscape.

The *Benefits of Biodiversity* also discusses the dependence of modern agriculture upon ecosystem services, such as pollination, generation of soils and renewal of their fertility, pest control and decomposition of wastes. It acknowledges the importance of preserving biodiversity by protecting natural areas and proposes that we substantially increase the worldwide network of biodiversity reserves and preserve large blocks of land in native ecosystems.

This report was not produced by CAST for the purpose of rerouting agriculture from the direction trends are leading. However, if followed, just one recommendation would lead us toward a landscape of farms that are natural habitats:

> Increase the capacity of rural landscapes to sustain biodiversity and ecosystem services by maintaining hedgerows/windbreaks; leaving tracts of land in native habitat; planting a diversity of crops; decreasing the amount of tillage; encouraging pastoral activities and mixed-species forestry; using diverse, native grasslands; matching livestock to the production environment; and using integrated pest management techniques.

The six farmers who participated in the Land Stewardship Project's monitoring project use many of these practices and have created more natural diversity on their land. Just by converting cropland to pasture they created new habitat for soil microbes, insects, birds, reptiles, amphibians and small mammals. Species that would have been adversely affected by chemical pesticides and fertilizers used on crops found a more favourable environment in the pastures.

Because of the emphasis on diversity and biological monitoring in holistic management, farmers in the project became advocates of diversity and astute observers of wildlife. A newsletter distributed to monitoring team members contained the following notes in a column called 'Farmer Observations':

> Mike saw first red clover blossoms on June 6. Mike saw a hummingbird on clover in his extended rest pad. He suggests that each farmer photograph their rest areas and notice the smell intensified by flowering plants. Ralph saw two baby bobolinks on July 14. He noticed the young are bunching up and may move soon. (Land Stewardship Project, 1995)

These farmers are not conventional in any sense of the word. Mike and Jennifer Rupprecht pay meticulous attention to erosion control and species diversity in their pasture, getting excited when they find native prairie species on their land. Ralph Lentz likes to show people the prairie grasses in his pastures and to talk about how he has used managed intensive grazing to improve the stability of stream banks on his land (DeVore, 1998). Dave and Florence Minar began working with a local monitoring team, after the original LSP monitoring project concluded, in the area of Sand Creek, the tributary that dumps the most sediment into the Minnesota River. Art Thicke is ecstatic when he talks about the birds he sees while moving cattle – birds that were not there when those pastures were planted to corn and soybeans (King and DeVore, 1999).

The increase of grassland birds was not just a phenomenon on Art's farm or on the other five farms in the monitoring project. Other farmers in the Upper Midwest report that they see more grassland birds such as bobolinks (*Dolichonyx* *oryzivorus*) and dickcissels (*Spiza americana*) since they replaced row crops with grass pastures. The Agriculture Ecosystems Research Project in the agronomy department at the University of Wisconsin has been comparing continuously grazed dairy pastures with rotationally grazed pastures, and preliminary results show that many more birds and more different species use rotational pastures than use continuous pastures (Paine, 1996). The increased acres of permanent grass in pasture, combined with conservation reserve land that has been in grass for several years, has created large areas of habitat for game birds also. Additional habitat is created where trees are allowed to grow again along drainages in pastures that were formerly tilled fields.

The farmers actively engaged in the Land Stewardship Project's monitoring project, and many others practising monitoring as a result of studying holistic management, are protecting or restoring diverse colours and textures in the 'warp and woof of the land use fabric'. To nurture the diversity of wildlife they have come to appreciate, and the wildlife they have begun to understand as indicators of ecosystem health, these farmers are developing and protecting more habitat niches in wood lots, along roadsides, on orchard and pasture edges, and along streams and ponds. They are leaving areas in their pastures ungrazed during the nesting season for grassland birds and removing low areas in fields from cultivation to restore wetlands.

The important point is not that these farmers have become naturalists. The natural habitat they are creating on their land is not because they set out to entice native plant and animal species to reinhabit their farms. Their management decisions and farming practices are turning their farms into a natural habitat for humans, crops and livestock, *and* wild plants and animals too. Then, as they make the connections between biological diversity, the economic health of the farm and the quality of their lives, farmers have begun consciously to make decisions to encourage even more biological diversity on their farms. Such farms should be the model for agriculture in the 21st century. To make that happen, a large group of constituents are needed who understand the possibilities for farms to be natural habitats and to transform rural landscapes.

Building a Constituency

Aldo Leopold wrote that no government conservation programmes with their subsidies for farmers could cause landowners to take good care of the land unless they felt an ethical responsibility for it. The ultimate responsibility for conservation was the farmer's (Leopold, 1991). From the latest agricultural census, we can see that less than 2 per cent of the US population are farmers (USDA, 1997), and not all of them are the family farmers Leopold had in mind but include large-scale farmers managing thousands of acres, often on behalf of investors or on contract with corporations. There are not enough private landowners on farms to rescue the agricultural landscape from ruin, even if those that exist possess a strong land ethic. We would be foolish to depend upon giant producers and processors such as Tyson, IBP and Smithfield corporations to exercise a land ethic. Whose responsibility is it then? It is a public responsibility. Good farming produces public goods, and the public must support good farming. Instead of accepting industrial agriculture as a necessary evil and counting on regulations to soften its negative environmental and social consequences, the public (particularly conservationists and environmentalists) should use their dollars and their votes and their influence to bring about agroecological restoration.

If asked whether it is all right to consider agricultural land as an ecological sacrifice area, most conservationists would loudly say no. But without thinking about it, many have acquiesced to the inevitability of farms becoming corporate factories when they have been involved in state or national processes to establish regulations for feedlots. Activist organizations have worked for strong regulations of nonpoint source water pollution and confined animal feeding operations, and their chief opponents have often been farmers, or farm organizations, which has caused them to develop antagonism for farmers. Many have not had the opportunity to know farmers whose diversified livestock systems operate without need of regulations. If conservationists could get to know farmers who are stewards of the soil, water and the wild and learn about their management philosophy and the farming practices they use, perhaps they would see possibilities for making basic changes in US agriculture that would restore rural landscapes to greater biological diversity and environmental health.

Dave Palmquist, the interpretative naturalist at south-east Minnesota's Whitewater State Park, the most popular park in Minnesota with about one-third of a million visitors a year, knows a stewardship farm family. He has taken groups of campers 10 miles away from the park to visit the 275-acre farm owned and operated by Mike and Jennifer Rupprecht, one of the six farms in LSP's monitoring project. His reason: 'There's an increasing understanding you can't save the world within state parks. The sixty-five little pieces of Minnesota (state parks) aren't going to do it. If you have to go outside your park to tell an important story that relates to the park area, do that.' Palmquist believes that visitors are impressed. 'It's clear to the visitors that these farmers embrace diversity and see themselves as being part of the bigger environment. The more diversity, the more bobolinks, bluebirds, etcetera, they have on their land, the better they feel. If they can make a living there, maintain a family farm, and be gentler on the environment, that's very exciting for them' (DeVore, 1996).

This kind of agroecological restoration is occurring on many farms today, illustrating that farms can be managed to give rural landscapes a mixture of agricultural and natural ecosystems that preserve much of local biodiversity and provide ecosystem services essential to agriculture. We need the heirs to Aldo Leopold's thought and inspiration and those who respect the work of modern ecologists such as David Tilman and naturalists like Dave Palmquist to help society see this vision of the farm as natural habitat and work to turn it into reality.

Conclusion

This vision does not promise that a landscape of such farms will reproduce the ecosystem that existed before white Europeans conquered the land, but neither will it be covered with factories. When farms are factories, they produce commodities and profit for agribusiness and charge external costs to the land and rural communities. When farms are natural habitats for humans, domesticated crops and livestock, and also for wild plants and animals, they produce food and multiple other benefits for society. And such farms can be the sources for further ecological restoration in the landscape.

No doubt interspersing a variety of uses on farms will mean different problems to overcome than those we now face, both ecologically and economically, because we still have a lot to learn about farming with the wild. Creating farms as natural habitats will require more sophisticated strategies for disease and pest suppression in crops and livestock. It will also require greater emphasis on diversification and resilience and less emphasis on simplification and short-term fixes. These are problems in farming that require ecological solutions.

Farming-system problems can be solved. The perhaps intractable problem is how to influence social evolution so that a land ethic, and not pure utilitarianism, guides land use decisions. We need all people to look at farming with new eyes, to see the potential of the farm as natural habitat, and to refuse to accept the inevitability of farms becoming rural factories to serve the global economy. We must teach that 'the land is one organism'.

Feminism and Environmental Ethics: A Materialist Perspective[1]

Mary Mellor

Feminism and Environmental Ethics

An important starting point for the development of an environmental ethics must perforce lie in the experience and situation of women (Gruen, 1994). This is, however, not the only starting point. Human society has many other divisions besides gender, but this paper is specifically concerned with a feminist perspective on ethics. The core of my argument, one that has been made many times by feminists, is that women's lives in a gendered society are grounded in the materiality of existence, in the cycles of birth and death and bodily needs (Ruddick, 1990). However, in stressing the importance of a feminist analysis to environmental ethics, I would not want women to be seen as the solution to environmental damage and injustice and thereby deflect attention from the problem of male domination and exploitation of women and the natural world (Mellor, 1992a, p81). I wish to argue that a solution to the questions of environmental justice and environmental ethics needs to start from an understanding of the social relations underpinning current patterns of unsustainability together with an understanding of the material relations between humanity and nature. This involves a three-fold relationship between human and human and nature and a double dialectic, between human and human (patriarchy, capitalism, racism), and between humanity and nature.

This complex relationship requires a breadth and depth of analysis that can integrate an analysis of social relations with ecological relations. In such a context all parts contain active elements. The relationship between humanity and nature is heavily circumscribed by relations between human and human. In turn, the dynamic between humanity and its natural context limits or constrains choices or brings unwelcome consequences. For this reason I would argue that a 'deep' analysis is needed, which I have called deep materialism. This analysis has three starting

points, the ecofeminist insight that there is a relationship between the subordination of women and the exploitation of nature, the deep ecologists' argument for a nonanthropocentric ontology and cosmology and the Marxist analysis of the dialectical relations of human material life.

The concept of deep materialism combines the adjective adopted by deep ecology and the analytical framework associated with Marx. I would argue that the insights of both are important and there is no necessary conflict between a radical approach to human–human relations and a 'deeper' approach to human–nature relations, although there are tensions between them in practice. The source of these tensions is the priority in different perspectives given to human–nature relations as against human–human relations. A radical approach to ecology such as that of Bookchin (1989) would see a fundamental reorganization of human–human relations as essential to resolving human–nature relations. Deep ecology, on the other hand, would see human–nature relations as the critical element. I would argue that the one is inseparable from the other, human–nature relations require reformulation of human–human relations and vice versa. Ecofeminists would agree with deep ecologists that humanity needs to completely rethink its orientation to the natural world, but like historical materialists would point to the socioeconomic context of such a relation. I would argue that Marx had at the heart of his work the double dialectical framework that I am advocating, but that his later analysis and, more importantly, later interpreters, took a humanist turn that lost the dialectic between humanity and nature. Marx's inability to develop his ideas in a more ecological direction was largely due to his acceptance of the sexual division of labour (Mellor, 1992b). Ecofeminists have also criticized deep ecology's tendency to concentrate on the relationship between humanity and nature to the exclusion of the dynamics of intra-human, and particularly gender, relations (Salleh, 1992). This leads to a tendency to adopt a depoliticized and even anti-human stance which places the blame for the ecological crisis on an undifferentiated 'humanity'. Ignoring social difference and inequality puts equal responsibility for ecological damage on the North and the South, rich and poor, black and white, men and women. This is not to imply that deep ecologists do not recognize the existence of what Naess called the relationship between 'man and man' (sic) but that this tends to remain theoretically unexplored. For ecofeminists the question of sex/gender difference/inequality is vitally important given the gendered nature of the relationship between humanity and nature.

Discussions of humanity, man, woman and nature are conceptually problematic. Humanity is divided in countless ways, as are men and women. I would not go along the postmodernist road that claims that there is no extra-discursive category of 'woman' (Riley, 1988), but it is easy to slip into universalizing and essentializing frameworks of thought when the words 'man' and 'woman' are used. Equally nature is a deeply problematic concept (Soper, 1995). I hope in the course of this paper to make clear the way in which I am using these words. However, to indicate the problematic and divided nature of humanity I will write this word in a broken form, hu(man)ity, in the rest of this chapter.

Ecofeminism and the Woman/Nature Relation

Ecofeminism has been identified as part of a 'deeper' or more radical approach to the ecological crisis (Merchant, 1992; Eckersley, 1992; Dobson, 1995). What is contentious in ecofeminism is the way in which the relationship between women and nature has been represented. Elsewhere I have made the distinction between affinity and socialist/social contructionist ecofeminism (Mellor, 1992a, 1996), that is between those who see women as having a bodily or cultural affinity with the natural world through their woman-ness as mothers, life-givers, nurturers, carers, and those who identify similar activities associated with women but see these as imposed upon women by male-dominated societies.

Affinity ecofeminists such as Andree Collard (1988) adopt a radical difference perspective seeing men/patriarchy as the source of eco-destruction and women as the contemporary representatives of an 'ancient gynocentric way of life' (p14) that exhibited 'nurturance-based values which women experienced and projected not only on their goddesses but on to every creature among them' (p8). The distinction between men and patriarchy implies that men are not necessarily bad, although Collard appears to wish to assert that all women are good. The source of women's affinity with nature is their common identity as mothers 'whether or not she personally experiences biological mothering' (p102). Men will be redeemed if they abandon patriarchy and embrace the values associated with women. What will motivate men to do so is less clear and as with much feminist writing that describes the patriarchal destruction of original matriarchal/egalitarian society the origin and nature of patriarchy is problematic. Collard suggests that male envy of women's ability to create life may be a psychological underpinning of patriarchy.

Affinity ecofeminism does not necessarily see masculine–feminine dualism as destructive. Instead they can be seen as complementary (Henderson, 1983). Cosmologically the masculine and the feminine are seen as the two complementary sides of a common hu(man)ity that have become disaggregated in ways that are socially and ecologically dangerous. Destructive behaviour occurs because masculine values are currently too dominant, more emphasis on feminine values are needed to restore the balance. I have described this as an ecofeminine rather than an ecofeminist perspective (Mellor, 1992c).

In contrast to asserting the affinity of women and nature, ecofeminists who come from an anarchist or socialist background tend to see sex/gender inequality as resting on other social inequalities. Women's association with nature is not explained by women's 'natural' affinity, but is socially constructed. Ynestra King (1990), from an anarchist perspective, sees sex/gender inequality as part of the wider question of hierarchy in society. She sees women as being 'historically positioned' at the 'biological dividing line where the organic emerges into the social' (pp116–117). Carolyn Merchant (1990), from a socialist feminist perspective, sees environmental problems as 'rooted in the rise of capitalist patriarchy and the ideology that the Earth and nature can be exploited for human progress' (p103). However, neither King nor Merchant seeks to radically dissociate themselves from cultural ecofeminism and the importance of valuing women and women's work. Merchant sees all the many strands of ecofeminism as being concerned with 'reproduction construed in its broadest sense to include the continued biological and social reproduction of human life and the continuance of life on earth' (p209).

Although ecofeminists often make generalized statements that seem to refer to all men and all women, their specific focus is the pattern of dominance that arose in European society associated with the historical development of science, technology, industrialism and capitalism. This is not to ignore the fact that earlier societies have been ecologically destructive (Ponting, 1991) or that ecologically benign societies can be patriarchal. It could be argued that male domination and women's oppression have been more ubiquitous in history than ecological destruction. The interesting question for ecofeminists is the way in which the two have come together in the present era. Ecofeminists see the origins of the present ecological crisis as lying in the specific material and cultural developments of the North/West as reflected in its socioeconomic structures, science and technology, philosophy and religion. For many ecofeminists, particularly those with a theological or a philosophical background, this destructiveness results from the forms of knowledge and belief that justify and sustain Western patriarchy. In particular, the Christian and rationalist rejection of the body and the prioritization of mind or soul (Ruether, 1975; Plumwood, 1993). Women are essentialized, naturalized and condemned by their association with the body. This association I would argue is the basis of the materialist analysis that can be derived from ecofeminism.

Materialist Ecofeminism

Materialist ecofeminism is based on the assertion that sex/gender inequality is not a by-product of other inequalities, but represents a material relation of inequality between dominant men and subordinate women. In terms of the double dialectic, the human–human relation is gendered in such a way that it interacts with the human–nature dialectic. Women are materially placed between 'Man' and 'Nature'. In a very real sense gender mediates human–nature relations, and *mediation* is a concept central to materialist ecofeminism. An environmental ethic between hu(man)ity and nature cannot be developed if this gendered relationship is not acknowledged. The second important element is the position of women as embodying nature both materially and symbolically in gendered societies. Unlike dominant men who claim to be above nature (transcendent), women are seen as steeped in the natural world of the body (immanent). The concept of *immanence* is therefore another central concept for materialist ecofeminism.

Affinity and social constructionist ecofeminism both see masculine/patriarchal values as inherently damaging and destructive, but even affinity ecofeminists do not see *men* and *women* as in fundamental conflict. Despite the initial impression given by their rhetorical language and condemnation of man/male and praise for women/the female, most do not see men as a lost cause. The problem arises with patriarchal structures which 'emerge' as cultural forms. When these structures are confronted and defeated, men and women can adopt a suitably earth-centred approach. For social constructionist ecofeminists, the most important structures that have created and/or sustained the hierarchical dualism of male–female are Western cultural and/or socioeconomic structures. This hierarchical dualism is symbolized by the emergence of a dominant public world based on a conception of rationality that seems to exclude women as participants (Lloyd, 1993) and the natural world as an entity worthy of moral concern (Plumwood, 1993; Warren, 1994). Although Plumwood and Warren would tend to see the cultural/philosophical framework of western society as fundamental, from a materialist ecofeminist perspective I would argue for an approach starting from sex/gender dualism as a relation of (re)production. This reflects a material necessity rather than a cultural/philosophical construction. In all human societies the need exists to construct the social within the constraints of the agency of the natural. This is exacerbated by the dualist and sexist structures of western society.

The dilemma of human embodiment exists as a fundamental feature of the human condition but it becomes most destructive in the divided societies of capitalist patriarchy where domination and transcendence of the natural world is central. With Ariel Salleh (1994) and Ynestra King (1990), I would argue that the sex/gender division of labour around human embodiment is the crucial factor. Women are materially associated with, and largely responsible for, human embodiment whether as paid or unpaid work. Although feminists have traditionally opposed women's association with the 'natural' work of mothering, nurturing, and caring, ecofeminists have followed cultural feminists in revaluing women's work. Materialist ecofeminism analyses the material relations of sex/gender in terms of the demands of human physical embodiment and ecological embeddedness. Unlike earlier traditions in feminism which sought to join male-dominated society in its seeming transcendence of natural conditions and the constraints of domestic life, ecofeminists have embraced immanence rather than transcendence. Immanence has been described by an ecofeminist exponent of the pagan tradition of witchcraft as the embracement of hu(man)ity within the alive-ness of the natural world (Starhawk, 1990). I would agree but would prefer to express these ideas in physical rather than magical terms. Alive nature may be, but it is not supernatural.

The dilemma for ecofeminism is that its two elements are in contradiction to each other. Although feminism has historically sought to explain and overcome women's association with the natural, ecology is attempting to re-embed hu(man)ity in its natural framework. Ecofeminism generally is incompatible with 'equal opportunities', liberal/equality/humanist feminism, and there are obvious dangers for the equalities that (some) women have achieved in going back to an association of women with nature whether it is on an affinity, social constructionist or materialist basis. From a deep materialist analysis it is not possible to see sex/gender relations as entirely socially constructed. It is no accident that women were associated with nature, it was not a mistake or some historical legacy as Ulrich Beck

(1992) has argued. As I will argue here, and have argued elsewhere, the association of women with nature represents hu(man)ity's need to confront its own materiality, its existence in ecological and biological time (Mellor, 1992a). The relationship is not a contingent one, an accident of historical association, it is a structural relation (Mellor, 1996).

Hu(man)ity as a natural species is embodied in its physical being and embedded in its natural context. Ecological time is the time framework of ecological renewal and of ecological change and evolution. Hu(man)ity can interfere with this to a large extent, but rarely without consequences in the long term, for even the most privileged, while in the short term it is the least privileged and other species who suffer most. Biological time is the life cycle and rest/renewal timescale of the human being. The centrality of women's socioeconomic position in this relationship is her responsibility for biological time.

The basic argument of materialist ecofeminism is that Western society has created itself against nature using the sex/gender division of labour as (one) of its vehicles. That is, power is defined by the ability of certain individuals and groups to (temporarily) free themselves from embodiedness and embeddedness, from ecological time and biological time. Ecological time as representing the pace of ecological sustainability for non-human nature. Biological time representing the life cycle and pace of bodily replenishment for human beings. It appears that throughout history women have carried the burden of biological time, and as Shiva (1989) has argued, in subsistence economies operated within ecological time. As Sanday's (1981) survey of anthropological data has shown, this left social space and time largely in the hands of men. Although men may have exploited their 'free' time in traditional society to make war, trade and politics, the position is much more dangerous in modern industrialized and militarized societies. The hallmark of modern capitalist patriarchy is its 'autonomy' in biological and ecological terms. The sex/gender and ecological consequences of economic activities are cast aside as 'externalities' (Mellor, 1997a). Western social and economic structures are based upon an idealized image of individuality. Western 'economic man' is young, fit, ambitious, mobile and unencumbered by obligations. This is not the world that most women know. Their world is circumscribed by obligated labour performed on the basis of duty, love, violence or fear of loss of economic support. To take their place in the Western public world, women have to present themselves as autonomous individuals, 'honorary men', avoiding domestic obligations, undertaking them in their 'free' time, or paying someone else to carry out that work.

Mediation in Human–Nature Relations

A materialist ecofeminist identification of women and nature is not based on an essential affinity, but reflects women's role as mediators of human–nature relations. It is not women's identity with 'nature', either as biology or ecology, that should form the basis of ecofeminism, but a material analysis of the way in which male domination is created and sustained. As Mies et al (1988) have argued, women are one of the 'colonies' of capitalist patriarchy. They are 'paying the price' (Dalla Costa and Dalla Costa, 1995). Women's identification with the 'natural' is not evidence of some timeless unchanging essence, but of the material exploitation of women's work, often without reward (Waring, 1989). It is not even always just the work that women do, but their availability. Someone has got to live in biological time, to be available for the crisis, the unexpected as well as the routine. Although materialist ecofeminism points to the particular dynamic represented in the sex/gender dualism, this is only one pattern of mediation. I see materialist ecofeminism as contributing to a wider debate about the material relations into which humans enter when confronting their embodiment and embeddedness. Marx's historical materialism addressed the social relations of class in this context. Later analyses have seen racism and imperialism/colonialism as equally, if not more, important. These dimensions are not in a hierarchy of oppressions, but rather a matrix that cut across each other (Collins, 1990).

Mediation involves both exploitation and exclusion. Mediation is making time, space or resources for someone else. Even so, the world is not clearly divided into mediators and the mediated. Many people stand in complex networks of mediation. Mediation is not only carried out by women, in fact, many women are themselves the beneficiaries of mediation. White Western women may mediate biological time for their family, but exploit the labour of others, the resources of the South, and the sustainability of the Earth. Many people live in complex networks of mediation on the basis of 'race', class, gender or ethnicity. The most destructive, however, are the industrialized societies of capitalist patriarchy that rest on a huge network of mediation through exploitation and exclusion: of women, of workers exploited or excluded on the basis of class, 'race' or gender, through the expropriation of colonized lands and the exclusion of colonized peoples. Environmental justice is about the social and ecological consequences of that 'freedom' exercised by the minority at the expense of the many (Hofrichter, 1993). The insight of ecofeminism that is common to both affinity and social constructionist ecofeminism is that the needs of human embodiment are shared by all hu(man)ity but are disproportionately borne in the bodies and lives of women.

Ecofeminism, in bringing together the domination of women with the domination of nature, brought into sharp focus the central dilemma of feminism: how could women's association with nature be asserted without falling into an essentialist and naturalist trap? The answer lies in not seeing women's oppression as representing their 'natural' affiliation with the natural world, but the connectedness of all hu(man)ity with nature. Women do have particular bodies which do particular things, but what matters is how society takes account of sexual differences and the whole question of the materiality of human existence. That is why I have linked the concepts sex/gender, to represent the interconnections of the biological and the social. Women are not closer to nature because of some elemental physiological or spiritual affinity, but because of the social circumstances in which they find themselves, that is, their material conditions in relation to the materiality of human existence.

In order to explore materialist ecofeminism as a perspective, it is necessary to bring together the green perspective on human–nature relations and a materialist feminist perspective on sex/gender relations. In this sense materialist ecofeminism is more sympathetic to deep ecology than other radical ecological perspectives such as social ecology or ecosocialism (Pepper, 1993). Getting the relations between humans right will not resolve the ecological imbalance because the source of much of the conflict between humans is the unacknowledged problem of immanence. Although both Bookchin and Marx explored the dialectical nature of the relationship between hu(man)ity and the natural world, other aspects of their work have prioritized hu(man)ity at the expense of non-human nature. Bookchin (1995) has called for the 're-enchanting' of hu(man)ity as the focus of social and natural agency, and the later Marx and Marxism have focused upon the social construction of nature. More recently, however, Marx's green credentials have been reclaimed or asserted (Benton, 1996). From the following it is clear that Marx saw hu(man)ity as both embodied and embedded within its natural 'body':

> Species-life, both for man and for animals, consists physically in the fact that man, like animals lives from inorganic nature… Man *lives* from nature, i.e. nature is his *body*, and he must maintain a continuing dialogue with it if he is not to die … for man is part of nature… Communism as fully developed naturalism, equals humanism, and as fully developed humanism equals naturalism: it is the *genuine* resolution of the conflict between man and nature. (Marx 1844/1975, pp327, 348, italics in the original)

As I have argued more fully elsewhere (Mellor, 1992b, 1997b), Marx's theory does contain the basis for a deep materialist analysis, but for ecofeminism the more immediate and contemporary statement of hu(man)ity's relationship with the natural world has been developed by deep ecology.

Deep Materialism and Deep Ecology

Deep ecology contributes to deep materialism through its aim of re-evaluating the relationship between hu(man)ity and non-human nature. The problem is how is this to be achieved? What would motivate hu(man)ity (or those parts of it with the power to make fundamental decisions) to change its stance towards non-human nature? Obviously a changed ethic would achieve this aim, but I see this as the goal rather than the means. The weakness of ethical approaches is the question of political agency. Ethical approaches are by their nature idealist (and idealistic) and require a metatheory of the motor of social change, which Marx provides in his materialist challenge to idealism. Do ideas change social structures and relations or do changing structures produce new ideas? Obviously it is a bit of both, and the economic determinism that dogged Marxist theory underestimated the role of ideas in changing human consciousness/awareness. However, I would argue that a deep materialist analysis provides a firmer basis upon which to establish grounds for political agency than an idealist philosophical/ethical stance.

Deep materialism shares with deep ecology a view of nature as embracing hu(man)ity. As Eckersley expresses it (following Naess) the world is 'an intrinsically, dynamic, interconnected web of relations in which there are no absolutely discrete entities and no absolute dividing lines between the living and the nonliving, the animate and the inanimate, or the human and the nonhuman' (1992, p49).

The insight of deep, green thinkers has been the conception of the natural world as having its *own* ontological status. Non-human nature is not a social construction or a dead nature that transcendent humans can manipulate at will and without consequences. It is an alive nature that enfolds human beings. The radical ecological (and ecofeminist) criticism of Western culture is that its dualistic social structures and forms of knowledge ignore the fact that hu(man)ity is part of the natural world (Plumwood, 1993). Hu(man)ity is always immanent. Transcendence is socially constructed against 'nature'. The natural world is not dead or dumb or a product of the human mind, it is '*fundamentally material and subjective*' (Lahar, 1991, p37, italics in the original). It is real, dynamic, and always beyond human knowing in that imbedded hu(man)ity has no Archimedes point from which to assess the complex interrelations of all the forces of the natural world. Ecologically hu(man)ity exists in a condition of radical uncertainty.

The concept used by deep ecologists to express a nature-centred approach is ecocentrism as opposed to human-centredness or anthropocentrism. Despite the claims of deep ecologists to a holistic framework, nature-centredness (ecocentricity) in rejecting human-centredness (anthropocentrism) tends to see human society as out of step with 'nature'. This implies a dualist distinction between 'humanity' and 'nature', where nature is 'right' and hu(man)ity is 'wrong'. Ecocentrism is often expressed in a way that sees hu(man)ity as outside of 'nature', particularly in the emphasis on wilderness. 'Untouched' nature is more 'natural' than when peopled by human beings. From a deep materialist perspective I would argue that human beings are inside, not outside of the processes of life. They have evolved out of the physical materials of this planet and their intelligence and destructiveness is part of that natural process. Nature does not have moral position on hu(man)ity. Hu(man)ity just is, as it is. It is for hu(man)ity itself to judge the ecological impact of its own existence. In this sense we cannot escape human-centredness. Nature is how we see it now. However, where the deep ecologists are right is to accuse modern humanism of arrogance in its attitude to the natural world. Human beings, no matter how powerful, cannot determine the ultimate conditions of their own existence. Nature will go on with or without hu(man)ity. The concept I would use to express the immanence of the human condition and the need to embrace a more nature-aware ontology is ecological holism. Ecological holism sees hu(man)ity as part of a dynamic interactive ecological process where the whole is always more than the sum of its parts (Mellor, 1997b, p185).

Ecological Holism and the Limits of Deep Ecology

In denying the moral worth of human agency, deep ecologists have a problem in making the jump from an ontological assertion of human interconnectedness with the natural world to the philosophical grounds for political action that goes beyond moral extensionism (Devall and Sessions, 1985; Devall, 1990; Fox, 1990; Eckersley, 1992). Where a deep materialist analysis would look at the material relations of hu(man)ity's (mal) connectedness with its encompassing environment, deep ecology tends to adopt an idealist framework as in Devall's and Sessions's (1985) concept of 'ecological consciousness':

> Deep ecology goes beyond the so-called factual level to the level of self and earth wisdom … to articulate a comprehensive religious and philosophical worldview … the basic intuitions and experiencing of ourselves and Nature which comprise ecological consciousness (p65).

A similar idea is expressed in Fox's (1989) transpersonal ecology with its notion of a transpersonal Self that represents the cosmos:

> deep ecologists emphasise identification within a cosmological context – that is, within the context of an awareness that all entities in the universe are part of a single, unfolding process (p11).

Following Naess, Fox (1990) argues that humans will understand nature's cosmology through an expanded sense of the Self. This is not the 'egoic, biographical sense of self', nor one that humans attain individually or collectively through ethical or political development, rather it is a Self that comes in from the outside:

> a transpersonal approach to ecology is concerned precisely with *opening* to ecological awareness: with realising one's ecological, wider, or big Self (p199, italics in the original).

Transpersonal ecology's cosmology requires a new way of looking at the world. For Fox this is the image of the cosmos as an unfolding 'tree of life'. We are all leaves on that tree. Adopting this new worldview through Self-realization and attaining ecological awareness, links hu(man)ity with the spontaneous unfolding of the cosmos. This is both teleological and idealist, reaching for the 'cosmic mind' of nature, a timeless essence revealing itself. The Naess/Fox/Devall/Eckersley approach to deep ecology claims that if true ecological consciousness were achieved, then moral injunctions would not be necessary:

> The cultivation of this expansive sense of self means that compassion and empathy naturally flow as part of an individual's way of being in the world rather than as a duty or obligation that must be performed regardless of one's personal inclination (Fox quoted in Eckersley 1992, p62).

The idealism of this perspective means that human–nature relations are not realized through the materiality of human connectedness to the natural world per se but by an individual appreciation of the *Idea* of connectedness. If such a cosmology is 'naturally' available, why does hu(man)ity not exhibit ecological awareness already? Ecofeminists argue that deep ecology fails because its concept of the self/Self is androcentric and therefore does not recognize the importance of the gendered nature of human–nature relations (Salleh, 1992; Plumwood, 1994; Mellor, 1997b).

Ecological Holism and Immanent Realism

In contrast to the idealist approach taken by most deep ecologists, I would see human envelopment in 'nature' as a material relation, an immanent materialism, that is the historical unfolding of the material reality of human embodiment and embeddedness within its ecological and biological context. However, I would not see this as having any particular direction in the sense of a determined outcome (which is implicit in both deep ecology and Marxism although in very different terms), although plainly some constructions of human–nature relations are more sustainable for hu(man)ity and current ecological conditions than others. Establishing a sustainable relationship for itself within its natural framework requires hu(man)ity to make political and moral choices. Human-centredness and the need for human appraisal of the social and ecological situation cannot be avoided. Nature has agency and history, but no mind or goal. Throughout my work I have argued for a politics of social and environmental justice based on feminist, green socialism (Mellor, 1992a, 1992b, 1993, 1997b). This inevitably means a struggle around ideas, but those ideas are grounded in a material analysis of the social and ecological context.

Materialist ecofeminism has strong links with critical realism (Plumwood, 1993; Hayward, 1994; Dickens, 1996) and feminist epistemology (Haraway, 1991; Harding, 1993; Rose, 1994). Critical realism challenges Western culture's attachment to positivist, scientific knowledge in terms of the social relations that are contained within them. As Hayward argues, 'sound critical social theory is as important as natural knowledge and ecological goodwill' (1994, p86). To this I would add the need for an immanent critical realism that would check the tendency towards assumptions of human supremacy in some critical social theorists. Bookchin (1995), for example, in his argument for the re-enchantment of hu(man)ity tips the balance of his dialectical naturalism towards human rationality and creativity. His approach is also teleological in that he sees hu(man)ity as at the apex of an evolutionary process. Hu(man)ity's job now is to rationally redirect the natural world. I would agree, but without the assumption of human supremacy. From the perspective of ecological holism and radical uncertainty hu(man)ity is an accidental outcome of nature, a momentary flicker in planetary history. If it is to remain for more than a brief moment, rational direction of its own history in relation to its natural context is essential for hu(man)ity. For this reason critical realism, based on a purely social critical theory, will not provide a solution. A deep materialist analysis would want to give more agency to the ecological whole and emphasize the radical uncertainty of human existence.

Hu(man)ity's immanence will always mean that any knowledge about the natural world is always partial. Even if a knowledge of all the components of the natural world was assembled this would never reveal the dynamics of the whole. The interconnectedness of all existence means that the ultimate consequences of any particular act can never be known. Immanent realism demands first of all a profound awareness of the ecological whole. There are many ways in which immanence could be 'realized'. It may be possible to achieve this through a scientific understanding, but it could also be achieved through the 'spiritual' awareness that many people feel when confronted by natural forces. Equally, the physiological experience of embodiment, embracing the realities of life, love and death, could be another channel of awareness. In this sense there is a material basis for the claim that an ethic based on women's lives and experience is likely to be more relevant to ecological sustainability. Spiritual ecofeminists are also perfectly logical in saying that it is possible to think through the body or experience holism as a spiritual force. It may be that ecological holism can only be experienced as a 'revelation', which could be described as wisdom. However, I would argue against seeing spirit as a metaphysical or supernatural concept, but rather as a particular property of human consciousness (Mellor, 1997b, p187).

Awareness of the radical uncertainty of human immanence should be the starting point of all other knowledge. This requires recognition of the *essentially* dialectical nature of the relation between hu(man)ity and the dynamic ecological whole. It would also recognize the independent agency of the interconnected whole. This does not deny human agency, but human agency would always need to show ecological reflexivity and humility. Such an approach does not take moral or political agency or even scientific knowledge from hu(man)ity, in fact it makes them all more vital. The loss of the positivist scientific assumptions that the machinery of nature will be revealed cannot be replaced by an equivalent assumption of a revelation of the holistic 'meaning' of nature. If the dynamic whole is unknowable by traditional scientific methods, why should it be any more 'knowable' through an ecological metaphysics?

Ecofeminism and the Politics of Deep Materialism

As I have implied earlier, I see no reason why hu(man)ity should be in harmony with a holistic nature. What is special about hu(man)ity is that it can grasp the tenacious nature of its existence. However, a transcendent dominant elite mediated by sex/gender and other relations of exploitation are unlikely to be motivated to 'see' the vulnerability of human immanence. Even when this vulnerability is grasped, this does not mean that hu(man)ity can reclaim an original harmony that has been lost or a teleological harmony to come as many green thinkers imply. If anything, hu(man)ity is *essentially* in conflict with non-human nature in using human consciousness and reflexivity to create a special and privileged niche. In doing this hu(man)ity is neither natural or unnatural. Therefore, deep ecologists cannot say 'nature' would be better off without hu(man)ity. However, hu(man)ity cannot exist without 'nature' and as there is no 'natural' way for hu(man)ity to relate to it, human existence in nature becomes a political and moral question. How can we live? How ought we to live? This is human-centred in orientation and motivation but the political conclusions would need at least to recognize the ecological framework of human activity. This would not satisfy deep ecologists but it would go much further towards balancing human–nature relations than most current political theory and practice. If, as I have argued, there is no natural balance in 'nature' and as hu(man)ity cannot transcend its ecological connectedness, a sustainable connectedness for hu(man)ity would need to be created through human reason and political action. In short, a politics of human–nature relations (Mellor, 1997b, p188).

Such a politics would start from an analysis of the structures that have created the present pattern of malconnectedness between the dominant structures within hu(man)ity and non-human nature. For ecofeminism, the subordination of women, particularly as represented in Western dualist social structures and patterns of thought, is central to understanding the destructiveness of current human–nature relations. In bringing together ecology and feminism, ecofeminists see women and nature as subject to the destructive socioeconomic and technological systems of modern male-dominated society. Sex/gender is put at the heart of this analysis, but this is not to exclude other cross-cutting dimensions of oppression and exploitation. To start with one oppression is not to claim that it has precedence, but to see if elements of the analysis may be useful in looking at other oppressions.

The focus of materialist ecofeminism on sex/gender inequality in the construction of human–nature relations does not collapse the social into the biological/ecological, but it does not seek to radically separate them. Materialist ecofeminism sees all hu(man)ity as embodied and those bodies are sexed. Gender does not map directly on to sex and sex itself is heavily socially circumscribed. 'Man' and 'woman' are the product of the interaction of biological and social factors. There is no essential or universal type of man or woman, but 'men' and 'women' do exist with enough commonality to make such concepts practically and theoretically useful. For materialist ecofeminism, there are aspects of women's bodies and social experience that can usefully be explored to help understand the current imbalance in human–nature relations. This imbalance has occurred within the context of a global system that is male-dominated, specifically by men from economically dominant societies with a history of war, militarism and imperialism, nationalism, racism and colonialism. The problem for such a society is how political change can occur. Certainly, there is the case for a struggle around ideas and ethical frameworks, but this has to be combined with struggle around material relations. The dualism at the heart of Western patriarchy is both material and cultural/ideological. Capitalist patriarchy justifies its transcendence through the promise of (eventually) extending transcendence to all, including those who are now locked into the hierarchical mechanisms of mediation. Universal transcendence is a promise that in ecological terms capitalist patriarchy cannot achieve. If it attempts to extend the patterns of consumption already achieved in the most successful economies, capitalist patriarchy will at some point run up against ecological limits. If capitalist patriarchy does not continue to extend its economic reach, it will fall victim to the classic Marxian problem of failure to realize profits and the inability to ideologically control those it exploits, excludes and oppresses.

The limitation of Marxist theory is that it only takes account of one form of mediation, class exploitation. Materialist ecofeminism would extend historical materialist analysis to all mechanisms of mediation. Political agency would rest with any peoples or groups who are exploited, marginalized or excluded by transcendent structures of social and ecological exploitation: people who have lost their land, economic migrants, bonded labourers, underpaid or unemployed workers, those suffering from biological and ecological hazards, floods, drought, pollution, industrial injury, ill health, people subordinated, oppressed and exploited on the basis of ethnicity, 'race' or gender. I would not want to make the case that all or any of these groups hold the answer to ecological sustainability or that they are likely to be more ecologically benign given the chance. The point is that their chances are limited socially or ecologically to a greater or lesser extent and this unites all these struggles. This is why building coalitions and coordinated political action are essential. Collective power will come from networks of people and groups all over the world making these connections, building coalitions of struggle not just around ideas but material conditions. The rather comfortable green concerns of the middle class in Europe, the US or Australia are not so indulgent if they are connected and identify with the campaigns of indigenous peoples for their land and cultural heritage, the position of the landless and the workless, ecologically and economically threatened communities, as well as campaigns around species and habitat (Mellor, 1997b, p192).

An ethics for social and environmental justice will not be 'given' to hu(man)ity by nature, it will always be a construct of human reason, informed by a critical awareness of the dynamics of socioeconomic power. However, developing such an ethic must take place against the background of a nonanthropocentric ontology. Hu(man)ity is essentially limited and framed by the unknowable and uncertain agency of the natural world. Immanent and alive nature embraces hu(man)ity. Failure to comprehend the materiality and material consequences of the human condition occurs where dominant social groups use the labour and resources of others (human and non-human) to mediate between themselves and their biological/ecological conditions. This is the three-way relationship of the double-dialectic of human–human–nature relations. The constraints of human existence as natural beings are mediated through unequal human–human relations. The development of an environmental ethics and the claim for environmental justice must be based on an analysis of these relations.

Materialist ecofeminism argues that the gendered nature of the relation between hu(man)ity and nature means that dominant males (and the females who associate with them) can live in conditions of unsustainable transcendence. Appeal to an environmental ethic may undermine these dominant groups, but it is important to recognize that all human beings are to a greater or lesser degree caught up in the web of mediation. Within that web three points of agency can be identified that may enable change to occur. The most obvious is the planet's own response to human action. The ecological effects of human action such as ozone depletion and global warming, unlike desertification and localized pollution, affect the dominant as well as the subordinate. Another locus of struggle are the campaigns by those who are subject to social and environmental injustice. Desertification, commercialization of land, destruction of local habitat, all produce economic and social dislocation and political responses such as land claims which the so-called 'developed' world is finding increasingly difficult to ignore. Finally, I would not want to underestimate the power of ideas and the growth of personal awareness. We are all embodied, and even the richest person can feel the limits of biological time.

The centrality of women's experience is that the work associated with subordinated women can mask the demands of biological time and its connectedness to ecological time for dominant men (and women) who claim transcendence over natural boundaries and limits. Thus an ethics from the standpoint of women makes political sense. It is not an essential statement about the *nature* of women or something universally attributable to women. Not all women do women's work and much is done by subordinated men. Women's work represents the immanence of human existence, the non-negotiable needs of the body. Failure to recognize this can lead to the destructive arrogance of claims to transcendence. These dangers are well expressed by Patricia Gunn Allen (1990):

> Walking in balance, in harmony, and in a sacred manner requires staying in your body, accepting its discomforts, decayings, witherings and bloomings and respecting them … Walking in balance requires knowing that living and dying are twin beings, gifts of our mother, the Earth … In the end you can't cheat her successfully, but in the attempt to do so you can do great harm to the delicate and subtle balance of the vital process of planetary being (pp52–53).

Gender and Social Capital: The Importance of Gender Differences for the Maturity and Effectiveness of Natural Resource Management Groups

Olaf Westermann, Jacqueline Ashby and Jules Pretty

Introduction

It is increasingly well established that social capital is an important factor in building and maintaining collective action (Krishna and Uphoff, 1998; Pretty, 2003; Pretty and Ward, 2001; Putnam et al, 1993; Scoones, 1998; Woolcock, 1998), which is in turn fundamental to substantial and long-term changes in natural resource management (NRM) (Agrawal and Gibson, 1999; Baland and Platteau, 1996; Bromley, 1992; Korten, 1986; Ostrom, 1990; Pretty, 2002; Pretty and Smith, 2004; Reddy, 2000; Steins and Edwards, 1999; Wade, 1987). Analysis of causal relationships among improved resource management and collective action has hitherto centred on the existence or creation of appropriate institutional and property arrangements (Bromley, 1992; Leach et al, 1999; Olson, 1965; Ostrom, 1990), but there is an emerging recognition that relations of trust and common values are important to collective action (Harris and Renzo, 1997; Lyon, 2000; Pretty and Ward, 2001; Uphoff, 2000). Particular attention has been given to the concept of social capital, broadly understood as a social resource 'upon which people draw when pursuing different livelihood strategies requiring coordination and collective action' (Scoones, 1998, p8). However, as Krishna (2000) concludes in an analysis of the implications of differences in social capital, little is known about how to tailor programmes to building social capital based on such differences. In this chapter, we argue that the role of gender differences may be of particular importance to understand and create social capital in order to sustain NRM groups. Although the gender dimensions of NRM have been identified as key factors

shaping peoples access to and use of natural resources (Agrawal, 2000; Cleaver, 1998a; Poats, 2000), most discussion of social capital so far appears to have been almost gender blind (Molyneux, 2002) or even critical toward women's role in the formation and maintenance of social capital (Riddell et al, 2001). Consequently, analysis of gender biases of social capital, understood as collective action that (re)produces gender discrimination, that is, reinforces male dominated power structures and excludes women from participation and decision making, is also almost non-existent. Thus, the hypothesis that gender influences NRM through different, gender-related stocks and usages of social capital requires further examination and empirical testing.

Classifying social capital as 'institutional', based on transactions governed by roles, rules, procedures and organizations or as 'relational', and so governed by norms, values, attitudes and beliefs, suggests that different strategies are needed for building social capital to support collective action for NRM. Krishna (2000, p79) indicates that in situations where relational social capital is strong but institutional capital is weak, collective action interventions will need to introduce rules, procedures and skills to build institutional capital on a relational capital base. Conversely, where rules, procedures, roles and organizations are in place to support collective action, but mutual trust is low and little value is placed on collaboration, interventions will need to build trust and willingness to work together, and create relational social capital (Krishna, 2000, pp80–88). In this paper, we conclude that the distinction between relational and institutional social capital is highly pertinent to understanding the implications of gender differences. Thus, neglect of the gender dimensions of social capital might lead to misleading conclusions about optimal intervention strategies. We investigate the different processes and outcomes in 46 men's, mixed and women's groups in 33 rural programmes in 20 countries of Latin America, Africa and Asia.

Gender, Social Capital, and the Environment

Discussion on the gender aspects of development and environment has its origins in the theories of Women, Environment and Development (WED), which highlight women as having a special relationship with the environment due to their responsibilities for the family and concern for the well-being of future generations (Jackson, 1993; Manion, 2002; Martine and Villarreal, 1997). In this approach, women are seen as 'a transcultural and transhistorical category of humanity with an inherent closeness to nature' (Jackson, 1998, p314) and thus likely to be the principal managers of the environment at local level (Green et al, 1998).

A number of alternative perspectives have also emerged that are less biologically determinist about women's roles in development and environmental management. These include gender analysis (Jackson, 1993), feminist political ecology (Rocheleau, 1995), feminist environmentalist (Agrawal, 1992), and the micropolitical economy of gendered resource use (Leach, 1991). All support the argument that gender differences in NRM are not due to women's inherent closeness to nature but due to 'dynamic and complex gender identities in which men and women experience both shared and divided interests' (Jackson, 1998, p315). According to these authors, gender differences in environmental relations and management should be understood as, and equated with, social relations.

Gender differences in needs and endowments may be key determinants of ways in which men and women manage natural resources. The relationship between women and nature is frequently analysed in terms of the increasing dependency on natural resources poor rural women experience due to poverty. In what has been termed the feminization of poverty, women have been identified as often carrying the main burden of poverty due to the over-representation of female-headed households among the poor who depend more on common pool resources (Jackson, 1993; Martine and Villarreal, 1997). Simultaneously, it has been claimed that the household division of labour and women's responsibility for family provision of household resources such as water and fuelwood makes women both more dependent on common property or open access to natural resources and at the same time more vulnerable to the negative effects on rural livelihoods of resource degradation (Manion, 2002).

Despite the case for viewing gender differences and gender relations as influential in NRM decisions, gender has been largely absent from efforts made to define social capital (Molyneux, 2002; Riddell et al, 2001). However, several studies have found that men and women may have different kinds and qualities of social capital based on differences in their social networks, values of collaboration, levels of conflict and capacity for conflict management. With respect to social networks, a number of researchers have found that women often depend more on informal relations and so form stronger kinship and friendship relations than men, who tend to rely more on formal relationships (Agrawal, 2000; Molyneux, 2002; More, 1990; Riddell et al, 2001). However, structural variables (such as number of children, marital status, age, employment status, income and occupation) can be more important for explaining differences in their social networks than gender (More, 1990).

Molinas (1998) found that successful collective action is dependent on the degree of women's participation. This is consistent with the argument that women exhibit more cooperative behaviour than men due to greater interdependency and altruism (Folbre, 1994; Sharma, 1980; White, 1992). However, Jackson (1993) emphasizes that the assumption of women's greater altruism is evidence of a common failure to scrutinize the private interest of women adequately. Women cannot be seen as a uniform category but a diverse group of people who vary according to class and culture as well as resource endowments and decision making power both between and within households. Molyneux (2002) also criticizes the assumption that women are more altruistic for not questioning the power relations that limit women's participation in formal organizations and so cause women more to rely on informal networks. Hence, the 'naturalization' of women's cooperative behaviour could be abused by targeting women for voluntary 'unpaid' work.

Agrawal (2000, p292) on the other hand, without rejecting possible gender differences in informal relationships and altruism, finds that the key to understanding such gender-differentiated social capital has to be found in the dependency of social networks and value of collaboration as the gender division of labour often obliges women to work in groups. She suggests that

> women have a greater need to build up social capital through localized networks, since women's avenues for accumulating economic resources and their physical mobility is typically more restricted than men's. They also have a greater need to sustain these networks, given their fewer exit options and lesser intra-household bargaining power.

Gender differences in conflictiveness and capacity to resolve conflicts may also reflect power relations that make women more vulnerable than men to the negative effects of conflict. According to several authors (Agrawal, 2000; Cleaver, 1998a, 1998b; Moser and Mcllwaine, 1999), women are often more affected by conflict because they are more dependent on informal networks of collaboration. But Agrawal (2000) suggests that such interdependence helps to overcome social division and to facilitate conflict resolution.

In summary, gender relations have been identified as important determinants of the capacity for collective action for NRM. Gender differences in several aspects of social capital have also been identified or hypothesized, but these two strands of analysis in the literature have not been well integrated. Several important and unanswered questions have practical implications for policy and programme design. To what extent do women and men demonstrate different NRM outcomes based on collective action? Do women tend to build and use social capital more readily than men, and if so, is this associated with gender differences in NRM? Moreover, gender-differentiated social capital may not be inherently beneficial to NRM if social capital upholds or increases exclusion and discrimination. Thus, if gender-differentiated social capital exists, is this due to innate gender-related attributes, the poverty of most rural women, or the underlying differences between men and women in power, influence over decision making, and control over assets? Thus, do NRM interventions relying on collective action for success need to include gender-differentiated strategies for building and using social capital?

In this paper, we analyse the different and complementary roles of women and men in social capital formation and its use, and explore the potential consequences of gender differences for NRM. We bring empirical evidence to bear on some aspects of the questions posed above. The analysis focuses on three broad propositions about the characteristics of gender differences in social capital:

1 Women and men commonly depend on different kinds of social relations or networks (Agrawal, 2000; More, 1990; Neuhouser, 1995). Women are often more dependent on informal networks based on everyday forms of collaboration such as collecting water, fetching fuelwood and child rearing. Such informal networks provide solidarity and access to household resources like water and firewood. Men are often engaged in more formal networks, such as project groups and community councils that improve access to economic resources and decision making (or power) (Agrawal, 2000).

2 Women and men may value collaboration differently. Women often have more everyday experiences of informal collaboration based on reciprocal relationships and higher dependence on social relations for access to household resources (Agrawal, 2000; Cleaver, 1998b). At the same time, it is often assumed that women reveal more relational and altruistic behaviour due to their role and responsibility for reproduction (Folbre, 1994; Sharma, 1980; White, 1992), and are less motivated by selfish individualism (Molyneux, 2002), while men are more individualistic and more engaged in formal collaboration, decision making and organized power structures.
3 Women are better able to overcome social division and conflicts (Agrawal, 2000; Cleaver, 1998b; Moser and Mcllwaine, 1999), because of their greater interdependency and their everyday experiences of collaboration. As a consequence, women are expected to perform better in groups, and – also as a result of their greater dependency on natural resources due to the household division of labour – to achieve better outcomes from collective NRM (Agrawal, 2000).

Framework and Methodology

Examination of the complex causal relationships between gender and collective NRM through different gender-related stocks and usage of social capital requires an innovative three-dimensional framework that combines elements of gender analysis, collective NRM, and social capital based on previous frameworks developed for environmental collective action (Agrawal, 2000; Krishna, 2000; Pretty and Frank, 2000; Pretty and Ward, 2001): The three dimensions employed for our analysis comprise:

1 The effects of gender on social capital based on the three propositions on gendered social capital described above that refer to social relations in networks, collaboration and conflict management.
2 The impact of gender on the effectiveness of collective action measured in terms of the maturity of groups (Pretty and Ward, 2001).
3 The effects of gender on the results of NRM measured in terms of a group's learning approach to NRM (Pretty and Frank, 2000).

Combining these three dimensions of the relationship between gender, collective action and NRM, our analysis assesses five features of collective action in NRM groups: (1) collaboration; (2) social relations in networks; (3) conflict management; (4) group maturity; (5) impact on NRM. Each of these five variables is now defined in detail below.

1 *Collaboration* – defined here in terms of five dimensions: frequency, value, purpose, type and structure of collaboration. To examine the frequency by

which group members collaborate, we examined (i) how often the groups get together for meetings or specific activities and (ii) how often the group's members work together outside the group (by collaboration 'among group members outside the group' we refer to situations where two or more members of the group get together and collaborate on an informal basis on activities that are not necessarily related to the specific objectives of the group). To measure the value placed on collaboration, we analysed the dichotomy between altruism and working for the common good *vs* selfishness and participation for personal benefit. This was measured through respondents' assessment of whether group members participated for the purpose of individual gains (such as resources and higher personal status) and/or whether their main motive of participation was a desire to contribute to group or community benefit. Because such judgement is naturally prone to bias, we have sought to revise the analysis through triangulation of similar issues. These include level of solidarity among group members in situations of emergency or need, as well as group members' specific incentives or purposes of collaboration including access to monetary resources or credit, access to agricultural inputs or land, access to decision making, access to collaboration and mutual help and opportunities to socialize (i.e. psychological benefit of belonging to a group). Based on the three propositions about gender differences in social capital discussed above, we would expect to observe higher values related to collaboration, and higher frequency of collaboration in groups where women are present, and the highest levels of collaboration in women-only groups.

2 *Social relations or networks* – defined here as a set of people (or organizations or other social entities) connected by a set of social relationships (such as kinship, friendship, labour groups) that enable the flow of resources and information through them (Garton et al, 1997). We focus specifically on bonding connections (between individuals in the group) and less on bridging connections (horizontal between the group and other local groups) and linking connections (vertical connections between the group and external organizations). To examine bonding connections, we analysed in-group relationships among individuals dividing them into relational (family, friends and neighbours), functional (cooperatives, community councils and external projects), symbolic (ethnic, religious and political), and place-based relationships (historical and cultural attachment).

3 *Conflict management* – defined here according to the frequency of differences in groups that lead to conflict, and capacity to resolve disagreements. If gender differences influence capacity to manage conflict we should, according to the propositions on gender and social capital and women's capacity to overcome social division and conflict, expect to find fewer incidences of conflict and a higher capacity (from non-existing to very high) to resolve the existing ones among women's groups as compared to men's and mixed groups. This again should coincide with dependency on and values of collaboration previously measured in terms of frequency of collaboration as well as values of altruism and solidarity.

4 Group maturity, here defined as NRM groups' 'potential for self-defining and self-sustaining activity' (Pretty and Ward, 2001, p209), has been operationalized in previous research into a series of criteria which can be found at three levels of development termed reactive dependence, realization independence and awareness interdependence. We measure these stages of maturity on the basis of seven criteria: (i) group objectives in relation to NRM which reflect whether the group is reactive, regenerative or innovative; (ii) the group's views on change (whether avoiding change, adjusting to change, or creating new opportunities); (iii) whether the group monitors and evaluates its own progress; (iv) the degree of reliance on external facilitators to solve problems; (v) collective or individual planning and testing; (vi) the importance of external aid for the formation of the group; and (vii) resilience or likelihood of the group breaking up. Effectiveness or the potential for self-defining and self-sustaining activity is operationalized principally in terms of increasingly supportive values and attitudes toward self-organizing collective action. If there are gender differences in social capital that strengthens internal group relations, then we would expect group maturity to be positively related to the proportion of women in a group.
5 NRM impact is defined here in terms of the management and learning approach to NRM adopted by the groups. The three categories used are (i) reactive (focused on eco-efficiency by reducing cost and environmental harm); (ii) regenerative (adoption of regenerative technologies and some principles of sustainability); (iii) redesign (innovation according to ecological principles, no longer adopting new technologies to fit the old system, but innovating to develop entirely new systems of management). The three categories of NRM are indicators of the evolution of the capacity of a group to engage in a progressively more sophisticated learning process approach to NRM (Argyris and Schön, 1978), and is evinced by a progression along a continuum from remedial measures to changing current practice and ultimately to fundamental innovation (Pretty and Frank, 2000). NRM innovation in a collective action situation requires high levels of trust and networking to promote knowledge sharing and confidence in reciprocal support from the group in the face of risk. If there are gender differences in the stock and usage of social capital, and if these affect innovation in NRM, then we would expect to find that groups with a higher proportion of women have a higher probability of being at the innovation stage in the continuum of NRM.

We examined the NRM outcomes that groups achieved, providing respondents with 12 options from which they could select freely. These options were designed to show whether groups had adopted a reactive or regenerative learning approach to NRM. In this analysis, we could not include options for redesign, as these should be innovative beyond current knowledge. However, respondents had the possibility to describe such novelty in the 'others' category of the questionnaire.

In total, we examined 46 different randomly selected groups (responses received from questionnaires conveyed to more than 500 NRM programmes all over the world) related to 33 programmes working on NRM in 20 countries of Latin America, Africa and Asia (see Appendix A). All groups had at least three years of working experience, and the majority were small groups with less than 50 participants. The programmes were drawn from databases on NRM from the Consultative Group on International Agricultural Research (CGIAR) system wide programme on PRGA, the IDRC MINGA programme, the World Bank, and the University of Essex (Pretty et al, 2003). The groups were concerned with a variety of NRM issues, including agrobiodiversity, agroforestry, coastal resources, food crop production, Integrated Pest Management, irrigation, soil management, and watershed and catchment management besides a number of programmes that work on a variety of multi-purpose activities with the objective to alleviate poverty through sustainable NRM. The groups represent all of the major categories of NRM groups identified by Pretty and Ward (2001) from eight countries in Asia, eight in South America and four in Africa.

The membership of six programmes' groups was solely men, eight were solely women and 32 were mixed. We recognize the difficulties of working with a category like 'mixed groups', in which women's and men's respective degree of participation may vary considerably and in which the exact gender composition of the groups and position of the group members is not explicitly measured by the questionnaire. Thus the 'mixed group' should be seen as a distinct category of group formation, creating different dynamics and providing unique opportunities for participation that are different from purely men's and women's groups. When compared with men-only and women-only groups, these mixed groups represent a phenomenon that allows us to investigate relationships between the presence of women (or men) in groups and overall group behaviour/performance.

In all, the groups in the sample contained some 1015 families, representing an average of 22 members per group. Despite the constraints of sample size, we were able to identify significant differences between some categories (maturity of groups, NRM achievements/approach and homogeneity of groups) and trends in others (frequency of collaboration, solidarity and capacity to manage conflicts).

These groups were surveyed using a questionnaire instrument containing 31 questions divided into the five themes mentioned above. These included (1) collaboration (characterization of the organization of the group, values of collaboration and experience of collaboration outside the group); (2) social capital in networks (local, local–local and local–external connections); (3) capacity to overcome social division and conflict; (4) indicators of the maturity of the group; and (5) NRM achievements and approaches. The questionnaire was prepared for response by key informants who were external programme facilitators (programme directors or workers with email access), and the answers are based on their assessment of types and levels of social capital in the groups and not on evidence of specific actions and relations as experienced by group members themselves. Reliance on a key informant assessment rather than a direct assessment by the people directly involved, that is, in our case, the members of the NRM groups, is a limitation of the data in particular when a subjective and qualitative assessment is involved. To moderate potential biases, we have put emphasis in the analysis on more tangible issues of social capital like frequency of collaboration and number of connections that can easily and objectively be reported by external observers. At the same time, we have avoided going into some of the more intangible aspects of social capital, such as trust and reciprocity that would require an insider perspective.

Another limitation of the study is the relatively small size and varied composition of the sample, which required careful selection of the statistical methods applied and triangulation of different measures. To analyse the data, we used three different statistical methods to determine differences between the groups: (1) frequency distributions of response for women's, men's and mixed groups; (2) Fisher's exact test of association between responses and type of groups; and (3) least significant difference test (LSD test) for women's, men's and mixed groups' averages in cluster of responses.

In order to compare the frequency of response for women's, men's and mixed groups, we have calculated and compared how often women's, men's or mixed groups have chosen a given option on the average. This analysis was conducted for all responses. We used Fisher's exact test to calculate whether the differences in frequency of response for women's, men's and mixed groups are significant. In our case, Fisher's exact test shows significant association when the value $Pr <= P$ is equal or less than 0.05 (95 per cent level of confidence) or when the $Pr <= P$ is equal or less than 0.10 (90 per cent level of confidence). To determine the difference among averages for cluster of responses, we use the least significant difference test, as it is useful for the comparison of five groups or less (we have three). To interpret the results of the LSD test, the LSD value is compared with the observed average differences. Means with the same t grouping letter are not significantly different because their differences are less than the LSD value. The LSD test was used to analyse clusters related to maturity of groups, local connections, types of collaboration outside the group and NRM achievements. Cluster analysis was carried out to analyse the relationship between group composition (women only, men only or mixed) and group maturity. First, multiple correspondence analysis was conducted of the seven variables used to define group maturity to generate scores for each group on dimensions that represent a combination of the proportion of the shared variance, and then cluster analysis of these scores was conducted using Ward's method (SPSS, 1994).

Results from NRM Groups

Similarities between men's, mixed and women's groups

Despite the clear differences in these programmes and their geographic locations, there were many similarities among the groups. With respect to motives for collaboration (altruistic *vs* selfish), no significant differences were detected among men's, women's or mixed groups – a key aspect of relational social capital and of the argument used by some early ecofeminists (Folbre, 1994; Sharma, 1980; White, 1992). We found that in around half of the groups, group members came together for common good and community purpose mainly (50 per cent of the women's groups, 66.7 per cent of the men's groups and 46.9 per cent of the mixed groups), while in approximately one-third of the groups, the majority of group members were collaborating because of the individual benefits such as resources and status they could gain from this. Moreover, 25 per cent of the mixed groups and 12.5 per cent of the women's groups had other reasons for collaboration, emphasizing participation for both selfish and altruistic reasons. This includes sharing of ideas and more sustainable management of natural resources.

More surprisingly, we did not find any evidence that women had stronger informal relations as indicated by kinship, friendship and neighbourhood relations (20 per cent for men's groups, 22.5 per cent for women's groups and 24.4 per cent for mixed groups), despite the well-documented research on social networks that suggests the fact that women have more informal and kinship related networks than men (Agrawal, 2000; More, 1990; Neuhouser, 1995). In general, the LSD test on group member's relationships did not reveal any significant differences among women, men and mixed groups' local connections (relational, functional, symbolic and place-based relations) except for the functional category where men had a significantly higher score than both the women's and mixed groups. However, it is worth noting that the principal relationship for all three groups is place based, which is consistent with the relatively high level of altruism and orientation toward the community by the majority of the groups. At the same time, all groups reported a very high level of cohesion with little likelihood of breakdown even after initial objectives had been fulfilled.

Gender differences in collaboration and solidarity

Although we found no gender differences in the value placed on altruism, the analysis of collaboration identified some gender differences in collaborative behaviour. Comparing frequency of collaboration, women's groups tend to meet more often than men's and mixed groups (Figure 12.1). Half of the women's groups meet on an average 1–2 times a week, much more frequently than the others: 83.3 per cent of the men's groups and 71.9 per cent of the mixed groups meet at most bimonthly. Women's groups also collaborate more frequently outside the group (Figure 12.2). Members of half of the women's groups collaborate on an everyday basis or 1–2 times a week, where only 16.7 per cent do so in men's and 31.3 per cent in mixed groups. Members of half of the men's groups collaborate outside the group only 1–2 times a year.

One explanation for the greater frequency of interaction by the women's NRM groups is revealed by analysis of group members' principal activities for collaboration outside the group (Table 12.1). Women's groups collaborate more on everyday household activities like cooking and child rearing than both men and mixed

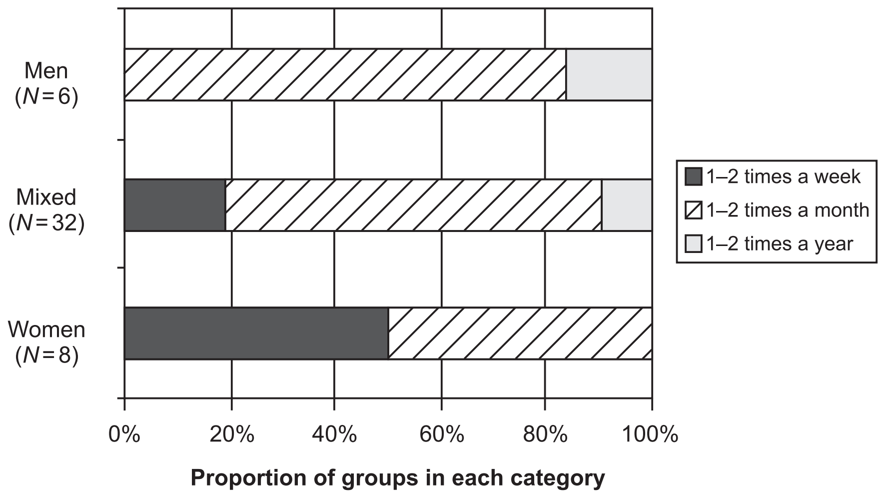

Figure 12.1 *Meeting rate for men's, mixed and women's groups*

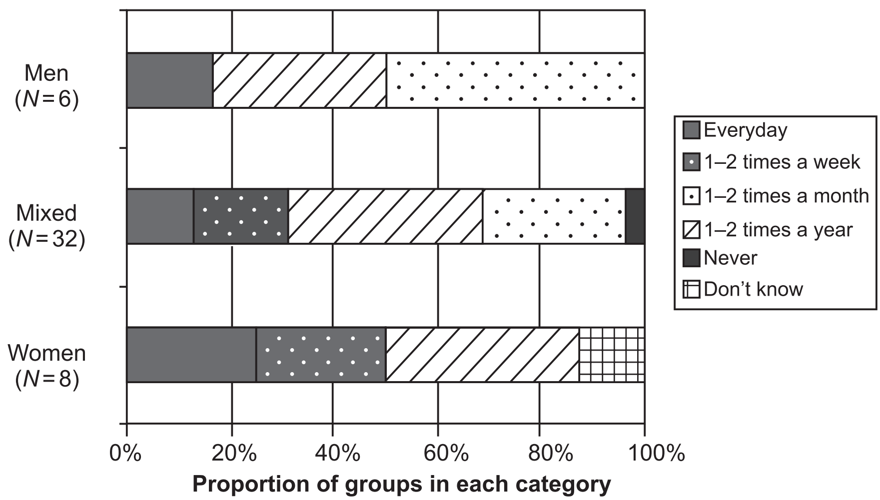

Figure 12.2 *Frequency of collaboration outside the group*

groups. In contrast, men's groups work together on less frequent activities like community infrastructure projects as well as in community boards and in externally facilitated projects. There is no significant difference among the group members' collaboration outside the group over agricultural activities (sowing, weeding and harvesting) and NRM (fetching fuelwood and collecting water). The main purpose of the group for collaboration is to also provide some insight into why women's groups meet more frequently. Access to monetary inputs or credit is the main purpose for meeting for the women groups and tends to be more important

Table 12.1 *Types of collaboration beyond specific group activities*[a]

Type of external collaboration	*Men's (N = 6)*	*Mixed (N = 32)*	*Women's (N = 8)*
Natural resource management (%)	8.3	9.4	0
Household (%)	0	0	31.3
Agriculture (%)	11.1	25.0	20.8
Community infrastructure (%)	33.3	18.7	8.3
Community organization (%)	9.8	7.0	3.1

[a] Least significant differences test for cluster of responses.

to women's groups than to men's groups only or mixed groups (31.3 per cent compared with 16.7 per cent for men's groups and 15.3 per cent for mixed groups) compared with other motivations for collaboration. Credit tends to require a high level of monitoring and turnaround.

Finally, solidarity tends to increase in groups where women are present. A majority of all types of groups report that they always or usually help fellow members in case of emergency, but mixed and women's groups report more solidarity compared to the men's groups: 90.7 per cent of mixed groups and 87.5 per cent of women's groups say they always or usually help fellow group members in case of emergency or need, while 66.7 per cent of men's groups indicate that they do this.

In summary, frequency of collaboration inside and outside the NRM group as well as solidarity is higher in groups including women, and this is mainly associated with collaboration in gender-specific tasks, responsibilities and needs. Our findings do not suggest that collaboration among women is related to the special value they place on altruism.

Gender differences and conflict

Fisher's exact test of the differences among the group shows a significantly higher homogeneity among members of women's groups than men's and mixed groups (37.5 per cent of the women's groups claim not to have significant differences among group members, while the figures for the men's groups and mixed groups are respectively, 0 per cent and 6.3 per cent). On the other hand, our results show no gender differences in the incidence of conflict (50 per cent of both men's and women's groups have no experience of serious conflict), but reported that the capacity to manage conflict tends to be higher in women's groups. Overall, 73.9 per cent of all groups report having demonstrated capacity (medium to very high) to overcome differences and conflict, but where women are present, groups tend to be better at managing conflict (50 per cent of the women's groups have high or very high capacity to manage differences and conflict, while only 33.3 per cent of men's groups and 40.6 per cent of mixed groups do so) (Figure 12.3). However, these results may be biased by the fact that the term conflict and the severity of

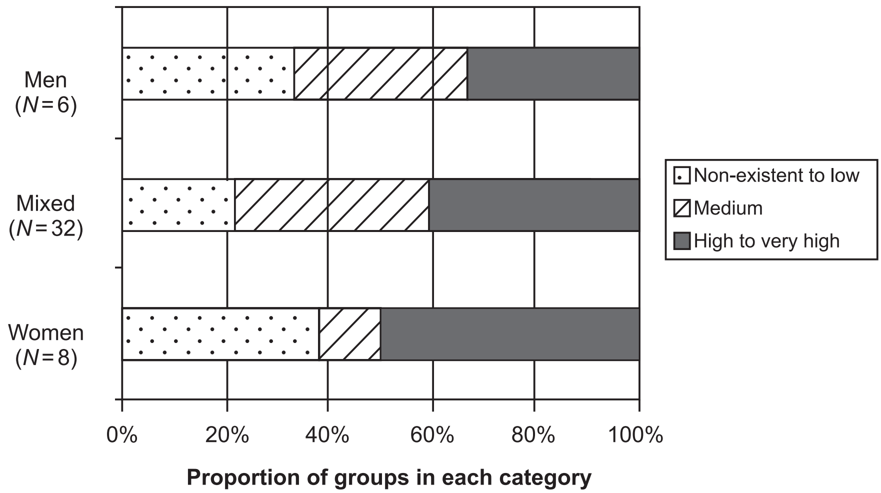

Figure 12.3 *Group capacity to manage conflict*

these could have been interpreted in different ways in the questionnaire. Consequently, respondents may have given their answers based on different understandings of the term 'conflict'.

Gender differences in group maturity

Group maturity refers to the effectiveness of groups to sustain collective action, measured according to seven criteria. Table 12.2 presents the frequencies for men-only, mixed and women-only groups on each of the seven criteria. Overall, men's groups are at an early, realization-independence stage of group maturity. Women's groups, by contrast, have a strong capacity for sustained collective action indicated by the stage of awareness interdependence in group maturity. It is important to note that maturity in this context does not refer to or correlate with age or duration of the group: our analysis also found that women's groups have fewer years of experience (3.9 years) than both the men's (5.3 years) and the mixed (5.7 years) groups. Table 12.2 shows that women's groups are more forward looking in terms of NRM and appear to have less fear of change. Women's groups also conduct self-analysis more regularly, which is consistent with their generally more frequent rate of meetings and collaborative actions. And finally, women's groups more often organize on their own behalf and with less external assistance than both the men and the mixed groups.

The conclusion that the presence of women in groups is likely to increase maturity or capacity for self-defined and self-sustaining collective activity on a long-term basis is supported by the results of the cluster analysis shown in Figure 12.4. Multiple correspondence analysis was carried out with two dimensions that are composites of group type and the criteria in Table 12.2. Dimension 1

Table 12.2 *Proportion of men's, mixed and women's groups measured according to seven criteria in each of three stages of maturity (stage 1: reactive dependent; stage 2: realization independent; stage 3: awareness interdependent)*

Seven criteria measured	*Group type*					
	Men		*Mixed*		*Women*	
	%	*N*	%	*N*	%	*N*
Group objective						
Stage 1: To conserve or restore a natural resource or resources to a previous status (the goal of the group is to restore what once was)	0	0	12.5	4	12.5	1
Stage 2: To adapt to a change in the status of a natural resource or resources (the goal of the group is to adjust to new realities)	66.7	4	46.9	15	12.5	1
Stage 3: To create new opportunities in managing a natural resource or resources (the goal of the group is to introduce something completely new)	33.3	2	40.6	13	75.0	6
Views of change						
Stage 1: The group is fearful of change, it is defensive	0	0	3.1	1	0	0
Stage 2: The group is adjusting to change, it is reactive	50.0	3	46.9	15	12.5	1
Stage 3: The group is creating new opportunities, it is proactive	50.0	3	50.0	16	87.5	7
Self-analysis						
Stage 1: The group has never evaluated its progress in meeting its objectives	16.7	1	0	0	0	0
Stage 2: The group sometimes evaluates its progress in meeting its objectives	66.7	4	59.4	19	25.0	2
Stage 3: The group regularly evaluates its progress in meeting its objectives	16.7	1	40.6	13	75.0	6
Problem solving						
Stage 1: Usually relies on help from outsiders to solve a problem	33.3	2	21.9	7	25.0	2
Stage 2: First tries to solve a problem itself before seeking help from outsiders	33.3	2	71.9	23	75.0	6
Stage 3: The group does not need outside facilitators to solve its problems	33.3	2	6.3	2	0	0
Planning and testing						
Stage 1: Individual planning and testing	16.7	1	12.5	4	0	0
Stage 2: Group planning and then individual testing	66.7	4	40.6	13	62.5	5
Stage 3: Group planning and group testing	16.7	1	46.9	15	37.5	3

Table 12.2 *(continued)*

Seven criteria measured	*Group type*

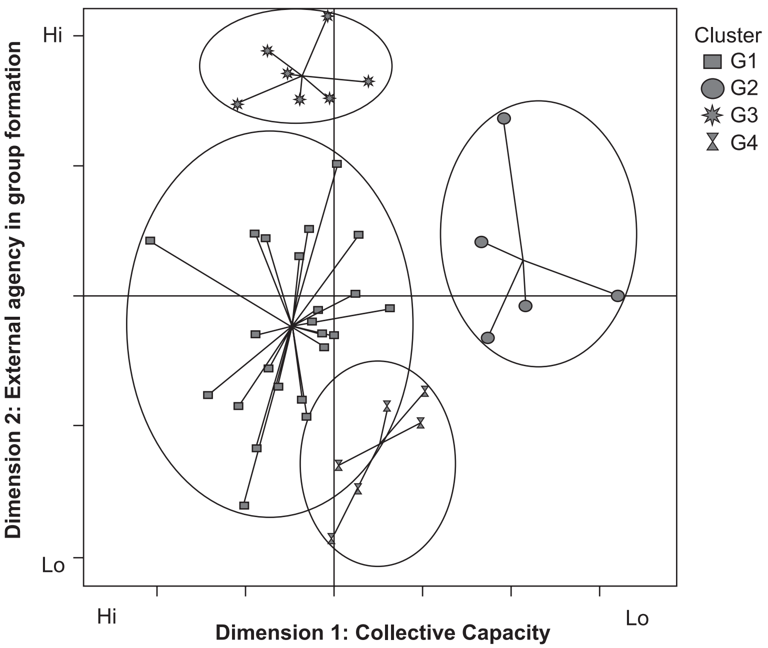

Figure 12.4 *Cluster analysis of group maturity*

represents 'collective capacity' as it is a composite of four variables: independence from external facilitators for problem solving, engagement in group planning and group testing, resilience, and women's presence in group composition. Collective capacity goes down reading from left to right in Figure 12.4. Dimension 2 is predominantly characterized by the variable 'group formation': thus, groups formed because an external agency asked them to do so cluster at the top as shown in Figure 12.4; groups formed without external agency cluster at the bottom. The most important cluster identified is Cluster G1, which is associated with groups formed without external agency. Groups in this cluster have women members; independence from external facilitators; group planning as well as group testing; and are considered unlikely to break down. This cluster is characterized by the presence of women in the groups: it includes all except one of the women-only groups and includes only one of the men-only groups. Cluster G3 differs from G1 in that its groups have been formed by external agency, and includes the one remaining women-only group. Cluster G2 and Cluster G4 consist of most of the men-only groups and are located mainly on the right-hand side of Figure 12.4, showing that collective capacity is lower in these clusters which are characterized by reliance on outsiders to solve problems as well as individual planning or testing.

Gender differences and NRM achievements

Gender differences were identified in the type of NRM achievements reported by the groups. Actual NRM achievements of the groups were classified in terms of their relation to different learning approaches – reactive and regenerative. Women's groups report a significantly higher proportion of regenerative outcomes than men's groups. There is no significant difference among groups in their reactive achievements. This difference among women's and men's groups is consistent with their responses to the survey question designed to elicit which NRM approach the group applies. These findings support the assumption of Pretty and Ward (2001) that NRM learning approach is related to group maturity. We show that the more mature women's groups apply more regenerative measures of NRM compared with the less mature men's groups.

Conclusions and Policy Implications

The analysis of different and complementary roles of women and men in social capital formation and the potential consequences of such differences for collective NRM in this study were guided by the proposition that women tend to build more relational social capital than men, that is, informal social relations and networks based on norms of collaboration and conflict management. The reason for this, it is argued, is that women supposedly value collaboration, altruism and conflict resolution more highly. Gender differences in stocks and use of relational social capital may translate into different NRM outcomes because norms of reciprocity facilitate collective management of natural resources by providing trust. Trust and reciprocity among actors at a personal and generalized level facilitate information exchange (and thus limit transaction costs) and so collaboration needed for collective action is enhanced. Collaboration which values solidarity and generosity may allow access to resources and discourage stakeholders from applying certain management practices that would affect others negatively. Women's relational social capital and values which support solidarity with other women may enable them to organize more effective collective action than men.

Our analysis reveals mixed results in relation to these propositions. On the one hand, propositions about the tendency of women to have altruistic values and informal relationships that endow them with higher social capital than men are not supported by this study. In groups formed for collective action in NRM, we did not find significant gender differences in relational social capital in terms of the reported value placed on altruism and the extent of informal kin relationships. On the other hand, we did find gender differences in the frequency of collaboration, solidarity and capacity to manage conflict where the data reveal an effect on group behaviour of the presence of women in groups. We found that collaboration, solidarity and conflict resolution all increase with women's presence in the groups, which is congruent with Molinas' (1998) and Odame's (2002) finding that women's participation increased cooperation. Our findings suggest that norms of reciprocity are more likely to operate in groups where women are present and that this may be the result of women's work responsibilities that rely on frequent collaboration.

Similarly, the capacity for self-sustaining collective action increased with women's presence and was significantly higher in the women's groups. The analysis demonstrated a significant relationship between (1) maturity of groups and gender and (2) NRM approaches/achievements and gender characteristics of groups. This result supports the finding from another study that maturity of groups is positively related to performance and management of natural resources (Pretty, 2003; Pretty and Ward, 2001). At the same time, we would be cautious about concluding that a more regenerative approach to NRM found in women's groups compared with men's more reactive approach is a direct result of higher awareness of ecological principles. This situation more likely reflects women's potentially higher dependency on common property resources and their limited access to external inputs.

The analysis provides clear evidence of the vital role of gender analysis for collective NRM and points to the importance of diagnosing gender differences in social capital in a community or a group before intervention in order to match the existing level of social capital with the need to organize for specific collective activities. It does not make sense to assume that women will automatically possess a higher stock of social capital than men. It will be important to examine how different gender-related needs, responsibilities and endowments, and in particular the gender division of labour, affect commitment to norms of reciprocity and collaboration.

However, we recommend careful analysis of the potentials for the spillover effect of gender-differentiated social capital in order to identify ways of taking advantage of the existing levels of social capital to strengthen the organization of collective NRM. Such an analysis must pay ample attention to the private interest of women and should consider whether and how collective action represents a resource from which different types of classes of women will benefit in different ways. Specifically, it will be important not to exploit women's potential for collective action to implement NRM projects that are not in their direct interest and to avoid reinforcing the 'dark side' of gender-specific social capital, which may be exclusionary and discriminatory. Women may depend more on some forms of relational social capital simply because they are excluded from male-dominated formal networks and organized power structures where institutional social capital is built and exercised.

Moreover, informal networks are needed to cope with multiple responsibilities for household provisioning, reproduction, child-care and risk management. Women's capacity for organizing effective collective action may not be related to, or depend on gender differences in the values, attitudes and informal relations that constitute relational social capital but on their opportunity for participation and even the sheer pressure of their workload. Based on the finding that mixed groups are an important type of organization where women's presence has an effect on group performance, we would rather suggest that attention should be exercised in forming and supporting mixed groups to ensure that women are given both a clear voice and decision making power. In mixed groups, women and men are likely to have different needs, capabilities and preferences, and to the extent that these differences are respected the presence of women in mixed groups is likely to raise the level of maturity and solidarity in the groups and so improve NRM outcomes. This would imply that an important focus of gender-sensitive capacity building and interventions to promote collective action would be to ensure that there is appropriate opportunity for women to participate.

Consequently, we recommend that interventions to promote collective action for NRM directly address the gender composition of group organization, and in particular the groups' relational and institutional social capital, and any norms, rules or networks that exclude women from participation and decision making. Such a recommendation necessarily implies readiness to challenge the structural positions from which women participate. To do so, it is critical to diagnose the power relations among men and women and comprehend their patterns of interdependence to be able to influence and facilitate gender relations and dynamics in collective action groups. Likewise, it is essential to assess the meaning of participation to women and men and understand better the dynamics and processes of how they draw on collective action resources in gender-differentiated groups.

Further research could usefully examine these issues to flesh out the dynamics underlying our finding that the presence of women in NRM groups tends to increase their effectiveness. Based on our results, we suggest that understanding gender relations is important for the sustainability of groups and how they may improve NRM. Krishna's question about how to tailor programmes to build collective action based on recognition of gender differences in social capital remains unanswered by our analysis. However, one implication of our findings is that in cases where women are high on relational social capital as our analysis revealed, but weak on institutional social capital, and where men have strong institutional social capital but are short of relational social capital, their capacity to organize effective group processes for collective action in NRM will vary. Gender differences in social capital imply that some form of intervention is required to construct institutional social capital in the form of enforceable rules, procedures and sanctions that can be used by women, or alternatively that relational capital is built in the form of enhanced trust, norms of collaboration and conflict management for men. Thus, we conclude that capacity building and interventions to promote collective action for NRM need to be gender differentiated.

Acknowledgements

We would like to thank all the people who have responded to the questionnaire survey, especially those who have dedicated time and energy to complete the questionnaires. We would also like to thank James Silva and James Garcia (CIAT) for their assistance with the statistical analysis and Christine Kolb (CIAT) for her assistance. We are also grateful to Rachel Hine (University of Essex), Sheri Arnott (IDRC), Helen Raij (IDRC-MINGA), Liliana Rojas (CIAT-REDECO), Peggy McKee (PRGA), and Ana Maria Ponce (CONDESAN – InfoAndina) for input regarding mailing lists and list servers and to Anna Knox (PRGA), Christine Okali, Gordon Prain and Helen Hambly for their comments on earlier versions of the paper. Finally we would like to thank the CGIAR Systemwide Program on Participatory Research and Gender Analysis for funding this research.

Social Capital and the Collective Management of Resources

Jules Pretty

From Malthus to Hardin and beyond, analysts and policy makers have widely come to accept that natural resources need to be protected from the destructive, yet apparently rational, actions of people. The compelling logic is that people inevitably harm natural resources as they use them, and more people therefore do more harm. The likelihood of this damage being greater where natural resources are commonly owned is further increased by suspicions that people tend to free-ride, both by overusing and underinvesting in maintaining resources. As our global numbers have increased, and as incontrovertible evidence of harm to water, land and atmospheric resources has emerged, so the choices seem to be starker. Either we regulate to prevent further harm, in Hardin's words (Hardin, 1968), to engage in mutual coercion mutually agreed upon, or we press ahead with enclosure and privatization to increase the likelihood that resources will be more carefully managed.

These concepts have influenced many policy makers and practitioners. They have led, for example, to the popular wilderness myth (Nash, 1973) – that many ecosystems are pristine and have emerged independent of the actions of local people, whether positive or negative. Empty, idle and 'natural' environments need protection – both from harmful large-scale developers, loggers and ranchers, as well as from farmers, hunters and gatherers (Callicott and Nelson, 1998). Since the first national park was set up at Yellowstone in 1872, some 12,750 protected areas of greater than 1000 hectares have been established worldwide. Of the 7322 protected areas in developing countries, where many people rely on wild resources for food, fuel, medicine and feed, 30 per cent covering 6 million km^2 are strictly protected, permitting no use of resources (Pretty, 2002).

The removal of people, often the poorest and the indigenous (Posey, 1999), from the very resources on which they most rely has a long and troubling history, and has framed much natural resource policy in both developing and industrialized countries (Gadgil and Guha, 1992). Yet common property resources remain

immensely valuable for many people, and exclusion can be costly for them. In India, for example, common resources have been estimated to contribute some US$5 billion yr^{-1} to the income of the rural poor (Beck and Naismith, 2001).

An important question is: could local people play a positive role in conservation and management of resources? And if so, how best can unfettered private actions be mediated in favour of the common good? Though some communities have long been known to manage common resources such as forests and grazing lands effectively over long periods without external help (Ostrom, 1990), recent years have seen the emergence of local groups as an effective option instead of strict regulation or enclosure. This 'third way' has been shaped by theoretical developments both on governance of the commons and on social capital (Ostrom et al, 2002; Singleton and Taylor, 1992). These groups are indicating that, given good knowledge about local resources, appropriate institutional, social and economic conditions (O'Riordan and Stoll-Kleeman, 2002), and processes that encourage careful deliberation (Dryzek, 2000), then communities can work together collectively to use natural resources sustainably over the long term (Uphoff, 2002).

Social Capital and Local Resource Management Groups

The term social capital captures the idea that social bonds and norms are important for people and communities (Coleman, 1988). It emerged as a term following detailed analyses of the effects of social cohesion on regional incomes, civil society and life expectancy (Putnam, 1993, 2000; Wilkinson, 1999). As social capital lowers the transaction costs of working together, it facilitates cooperation. People have the confidence to invest in collective activities, knowing that others will also do so. They are also less likely to engage in unfettered private actions with negative outcomes, such as resource degradation (Pretty and Ward, 2001; Agrawal, 2002). Four features are important: relations of trust; reciprocity and exchanges; common rules, norms and sanctions; connectedness in networks and groups.

Relations of trust lubricate cooperation, and so reduce transaction costs between people. Instead of having to invest in monitoring others, individuals are able to trust them to act as expected, thus saving money and time. But trust takes time to build, and is easily broken. When a society is pervaded by distrust or conflict, cooperative arrangements are unlikely to emerge (Wade, 1994). Reciprocity increases trust, and refers to simultaneous exchanges of goods and knowledge of roughly equal value, or continuing relationships over time (Coleman, 1988; Putnam, 1993). Reciprocity contributes to the development of long-term obligations between people, which helps in achieving positive environmental outcomes.

Common rules, norms, and sanctions are the mutually agreed upon or handed-down drivers of behaviour that ensure group interests are complementary with those of individuals. These are sometimes called the rules of the game (Taylor, 1982), and give individuals the confidence to invest in the collective good. Sanctions ensure that those who break the rules know they will be punished. Three types of connectedness (bonding, bridging and linking) have been identified as important for the networks within, between and beyond communities (Woolcock, 2001). Bonding social capital describes the links between people with similar objectives and is manifested in local groups, such as guilds, mutual-aid societies, sports clubs and mothers' groups. Bridging describes the capacity of such groups to make links with others that may have different views, and linking describes the ability of groups to engage with external agencies, either to influence their policies or to draw on useful resources.

But do these ideas work in practice? First, there is evidence that high social capital is associated with improved economic and social well-being. Households with greater connectedness tend to have higher incomes, better health, higher educational achievements, and more constructive links with government (Pretty, 2002; Ostrom et al, 2002; Putnam, 1993; Wilkinson, 1999; Krishna, 2002). What, then, can be done to develop appropriate forms of social organization that structurally suit natural resource management?

Collective resource management programmes that seek to build trust, develop new norms and help form groups have become increasingly common, and are variously described by the terms community-, participatory-, joint-, decentralized- and co-management. They have been effective in several sectors, including watershed, forest, irrigation, pest, wildlife, fishery, farmers' research and micro-finance management (Table 13.1). Since the early 1990s, some 400,000–500,000 new local groups were established in varying environmental and social contexts (Pretty and Ward, 2001), mostly evolving to be of similar small size, typically with 20–30 active members, putting total involvement at some 8–15 million households. The majority continue to be successful, and show the inclusive characteristics identified as vital for improving community well-being (Flora and Flora, 1993), and evaluations have confirmed that there are positive ecological and economic outcomes, including for watersheds (Krishna, 2002), forests (Murali et al, n.d.) and pest management (Pontius et al, 2001).[1]

Further Challenges

The formation, persistence and effects of new groups suggests that new configurations of social and human relationships could be prerequisites for long-term improvements in natural resources. Regulations and economic incentives play an important role in encouraging changes in behaviour, but although these may change practices, there is no guaranteed positive effect on personal attitudes (Gardner and Stern, 1996). Without changes in social norms, people often revert to old ways when incentives end or regulations are no longer enforced, and so long-term protection may be compromised.

However, there remains a danger of appearing too optimistic about local groups and their capacity to deliver economic and environmental benefits, as divisions within and between communities can result in environmental damage. Moreover not all forms of social relations are necessarily good for everyone. A society may have

Table 13.1 *Social capital formation in selected agricultural and rural resource management sectors (since the early 1990s)*

Countries and programmes	*Numbers of local groups (thousand)*
Watershed and catchment groups	
Australia (4500 Landcare groups containing about one-third of all farmers), Brazil (15,000–17,000 microbacias groups), Guatemala and Honduras (700–1100 groups), India (30,000 groups in both state government and NGO programmes), Kenya (3000–4500 Ministry of Agriculture catchment committees), US (1000 farmer-led watershed initiatives)	54–58
Irrigation water users' groups	
Sri Lanka, Nepal, India, Philippines, Pakistan (water users groups as part of government irrigation programs)	58
Microfinance institutions	
Bangladesh (Grameen Bank and Proshika), Nepal, India, Sri Lanka, Vietnam, China, Philippines, Fiji, Tonga, Solomon Islands, Papua New Guinea, Indonesia and Malaysia	252–295
Joint and participatory forest management	
India and Nepal (joint forest management and forest protection committees)	35
Integrated pest management	
Indonesia, Vietnam, Bangladesh, Sri Lanka, China, Philippines, India (farmers trained in farmer field schools)	18–36

Note: This table suggests that 417,000–482,000 groups have been formed. Additional groups have been formed in farmers' research, fishery and wildlife programmes in a wide variety of countries.

Source: See Pretty and Ward, 2001

strong institutions and embedded reciprocal mechanisms yet be based on fear and power, such as feudal, hierarchical and unjust societies. Formal rules and norms can also trap people within harmful social arrangements, and the role of men may be enhanced at the expense of women. Some associations may act as obstacles to the emergence of sustainability, encouraging conformity, perpetuating inequity, and allowing certain individuals to shape their institutions to suit only themselves, and so social capital can also have its 'dark side' (Portes and Landolt, 1996).

Social capital can help to ensure compliance with rules and keep down monitoring costs, provided networks are dense, there is frequent communication and reciprocal arrangements, small group size and lack of easy exit options for members. However, factors relating to the natural resources themselves, particularly whether they are stationary, have high storage capacity (potential for biological growth), and clear boundaries, will also play a critical role in affecting whether social groups can succeed in keeping the costs of enforcement down and ensuring positive resource outcomes.

Communities, also, do not always have the knowledge to appreciate that what they are doing may be harmful. For instance, it is common for fishing communities to believe that fish stocks are not being eroded, even though the scientific evidence indicates otherwise. Local groups may have the support of higher-level authorities, for example with legal structures that give communities clear entitlement to land and other resources, and insulation from the pressures of global markets (Ostrom, 1990; Ostrom et al, 2002). For global environmental problems, such as climate change, governments may need to regulate, partly because no community feels it can have a perceptible impact on a global problem. Thus effective international institutions are needed to complement local ones (Keohane et al, 1993).

Nonetheless, the ideas of social capital and governance of the commons, combined with the recent successes of local groups, offer routes for constructive and sustainable outcomes for natural resources in many of the world's ecosystems. To date, however, the triumphs of the commons have been largely at local to regional level, where resources can be closed access, and where institutional conditions and market pressures are supportive. The greater challenge will centre on applying some of these principles to open access commons and worldwide environmental threats, and creating the conditions by which social capital can work under growing economic globalization.

Still Going: Recent Debates on the Goldschmidt Hypothesis

Linda M. Lobao, Michael D. Schulman and Louis E. Swanson

Goldschmidt's (1978a) 1940s study of two California communities generated the hypothesis that large-scale farming has detrimental impacts while family-operated farms enhance community well-being. Research on the Goldschmidt hypothesis has gone through phases corresponding to transformations in the sociology of agriculture and broader rural sociology. This article discusses the present status of the Goldschmidt literature with a focus on a recent article by Barnes and Blevins (1992), which ignored the body of literature generated in the latter phase of the Goldschmidt debate. The result is that their article is premised upon discovering solutions to problems addressed even a decade earlier. However, as Barnes and Blevins (1992) once again raise interest in the Goldschmidt hypothesis, they provide a reason for stepping back and assessing what has been accomplished. Because all of us have participated in the discussion of the Goldschmidt debate, our commentary will draw particularly from our own research.

Goldschmidt's (1978a) *As You Sow* has become a requisite citation for research on rural well-being and economic structure. Early literature reflected numerous quantitative attempts to replicate and test the original hypothesis. By the mid-1980s, however, both the spatial and temporal generalizability of the Goldschmidt thesis were seen as limited. A new generation of researchers recast the Goldschmidt debate in light of post-war transformations of the farm and broader non-farm rural economy (Buttel et al, 1988; Flora and Flora, 1988; Gilles and Dalecki, 1988; Lobao, 1990; Lobao and Schulman, 1991; MacCannell, 1988; Skees and Swanson, 1988; Swanson, 1982; van Es et al, 1988). Theoretical extensions and methodological inroads were made as well. Barnes and Blevins (1992) point to the need to take stock of the new generation of research. In ignoring much of this body of literature, Barnes and Blevins (1992) repeat earlier critiques, discount methodo-

logical and conceptual issues raised by current researchers, and recover old ground regarding the Goldschmidt thesis.

The Goldschmidt Hypothesis

During the Depression, social scientists observed a new round of farm restructuring that differed from previous eras. This was manifest in the transformation and general decline of simple commodity production, the exodus of poor and tenant farmers from the South, and growth in the West of large-scale, hired-labour-dependent farming. The effects of this latter type of farming and the fear that it would replace traditional family farming were of particular concern to Goldschmidt (1978a) and others (Tetreau, 1938, 1940) who left less notable accounts. As Bertrand (Wimberley, 1991, p24) noted:

> We have sort of overlooked the studies that were done in the '30s as a result of the … disasters in Oklahoma and some of the dust bowl states. There was a lot of work that was sponsored at that time … [Paul] Taylor over in California made studies of the workers on the big fields and the social power mustered by the big owners, you know, put rural sociology completely out of the California university system.

Though others investigated similar issues, Goldschmidt's hypothesis that a trend towards large-scale farming and a concomitant decline of family farming jeopardize community well-being would become the paramount statement of the problem.

Because of the profound political implications of the topic and partly because of Goldschmidt's own lack of clarity, the notoriety of Goldschmidt's (1978a) study has persisted. For supporters, it represents a compelling defence of traditional family farming and assailment of corporate farming (Rodefeld, 1974; Strange, 1988; see also Goldschmidt's subsequent study, 1978b). Critics charge that it provides theoretical justification for neo-populist stances in rural sociology (Friedland, 1989). Economists have challenged its methodology, subjecting it to standards beyond those of the typical case study (Hayes and Olmstead, 1984). Goldschmidt's own lack of clarity as to the causal mechanisms by which farming affected communities undoubtedly contributed to the debate and numerous attempts to replicate this study. As has been long noted, whether Goldschmidt viewed scale or class position or both as central causal elements remains unclear (Goss and Rodefeld, 1979; Green, 1985). Swanson (1990) pointed out, however, that the concordance between scale and position is an empirical question: there is no reason why a growth in large-scale farming must be accompanied by a change in class structure. While this relationship has been observed in California, it has not been confirmed in the Midwest.

Looking Backward

Barnes and Blevins (1992) neglect much of what has been accomplished in the Goldschmidt debate. As a consequence, dated arguments are repeated and the analysis is subject to conceptual and methodological problems found in older studies. A brief review of the early Goldschmidt literature, its documented limitations, and the resulting new generation of studies provides a context to understand our critique of Barnes and Blevins.

The 1970s to early-1980s period

The 1970s through the mid-1980s represents an essentially knowledge-building and largely empirical phase in the Goldschmidt literature. In general, studies focus on replicating and testing Goldschmidt's hypothesis (Leistritz and Ekstrom, 1986). Different methodologies, regional contexts, and dependent variables or indicators of well-being are used to test essentially the same relationship: the effects of large-scale, hired-labour-dependent farming on communities and rural people. Specific studies and salient characteristics of this are summarized elsewhere and noted briefly here (Lobao, 1990; Swanson, 1990).

The purpose of most studies is to examine indicators of one or both farm concepts – scale (sales or acreage) and organization. The latter taps off-farm or non-family dependence on production factors and includes concepts such as land tenure, extent of hired labour use, managerial control and capital use. The studies conceptualize relationships in a generally linear manner, contrasting the effects of large as opposed to small farms. For example, they hypothesize that the larger the farm and/or the greater use of hired labour, the more negative the impact on well-being. Most research is limited to particular regional contexts. Findings are not directly comparable because of the different geographic settings, time periods and methodologies. Studies are mainly empirically driven, aimed at testing the effects of large-scale farming but not at drawing out conceptually why such effects may be expected. Conclusions are framed in simple defence or support of Goldschmidt rather than in recognizing the complexity of relationships that determine community well-being.

On balance, studies of this period tend to support Goldschmidt but few do so unequivocally. One of the first deviations recognized was that results depended upon the indicator of farm structure: larger-scale farming was not found to be related to poorer conditions in several studies (Flora et al, 1977; Harris and Gilbert, 1982; Swanson, 1982). Findings also diverged for other reasons, including the time period, whether well-being outcomes were measured by economic or non-economic indicators, regional location, unit of analysis and the modelling or shape of relationships (Lobao, 1990).

The mid-1980s to present: Critique and response

By the late 1980s, analysts recognized a series of problems with earlier studies that prevented closure on the Goldschmidt debate. A summary of these, with citations if previously made by other authors, is provided in Lobao (1990). 'The first problem concerns the conceptualization and measurement of farm structure. Researchers are often unclear about what aspects of farm structure (scale or organization) are relevant for assessing socioeconomic impacts' (Lobao, 1990, p67). Another issue is the adequacy of control variables for 'agricultural dependency, urbanization, or industrial activity … studies that delineate and control for nonfarm factors are needed to more rigorously test the impact of farm structure' (Lobao, 1990, p66). 'A further methodological criticism … involves the scope of the studies. Most have been confined to areas with specific types of agriculture which limits generalizability of findings. Only a few studies have examined the effects of farm structure for the entire United States' (Lobao, 1990, pp66–67).

Two years later, Barnes and Blevins (1992, p333) reached the same conclusions. They stated:

> First, there are problems with the conceptualization of farm structure. Second, most researchers fail to incorporate indicators of nonfarm structure into their studies. Third, most researchers lump together all nonmetropolitan counties. Finally, almost all existing research is restricted to selected states or regions.

Barnes and Blevins (1992), however, provide no citations as to the sources of these critiques, apparently believing that they are original.

By the late 1980s, other critiques that bear upon the Barnes and Blevins (1992) article had emerged, including those by Swanson (1988b, 1990) and Lobao (1990). Most studies are cross-sectional rather than longitudinal and thus cannot offer direct causal evidence about the impacts of change, nor whether farm change creates short-term or permanent imbalances in a community. There is also a tendency to view the relationship between farm and non-farm variables linearly. Smaller farms are thus presumed to be most beneficial. Causality is mainly one-way. Changes in farm structure are examined as independent variables or causes rather than effects of non-farm community structure. Finally, there are conceptual and theoretical limitations (Lobao, 1990). Researchers neglect to go beyond the original relationships set forth by Goldschmidt. This inhibits the development of a theoretical explanation of how farm change and broader restructuring of the rural economy affect well-being.

By 1990, two volumes of research as well as a number of journal articles had addressed these critiques. The Office of Technology Assessment (OTA) of the US Congress commissioned a series of studies on the effects of farm structure on community well-being that were subsequently published in Swanson (1988a). The studies focus on five regions (North-east, South, Midwest, Great Plains, West) and the highly industrialized farming states of California, Arizona, Texas and Florida.

The authors describe changes in post-war farming patterns typical of each region, then examine the effects of these changes on indicators of county well-being generally for the 1970–1980 period (Buttel et al, 1988; Flora and Flora, 1988; MacCannell, 1988; Skees and Swanson, 1988; van Es et al, 1988).

Also by the mid-1980s, two US Department of Agriculture regional research projects (S-198, S-246) centred on the changing structure of agriculture and its effects on communities. As part of these projects, Wimberley (1986, 1987) developed indicators of agricultural structure from a factor analysis of census agriculture data. His purpose was to describe empirically the changes that had occurred in post-war agriculture but that could not be captured through the use of single indicators of farm structure. To describe national patterns of farming, he created indexes for all counties with census-reported farming, the criteria generally being ten or more farms. While the vast majority (more than three-quarters) of these counties are non-metropolitan, Wimberley (1986, 1987) purposefully did not exclude any metropolitan counties for which farming was reported. Such counties typically contain highly capitalized operations that reflect important present and future structural trends. Wimberley found three dimensions of farm structure that correspond to post-war dualistic tendencies noted empirically and theoretically in the literature – small, part-time farming; highly capitalized, family-labour farming; and commercial-scale, hired-labour-dependent farming. Lobao (1990) employed Wimberley's indicators in a national study of socioeconomic inequality across counties. She viewed differences in local well-being as a consequence of economic structure (farm and non-farm), the power of workers and their households vis-à-vis employers, and spatial or locational characteristics. She also examined the extent to which generalized, national patterns hold for various regions. As most of the sample counties are non-metropolitan, and as a subsequent study (Lobao and Schulman, 1991) showed that the relationships stay the same when the few metropolitan counties are excluded, the study has particular policy implications for rural areas.

With regard to the relationship between farm structure and well-being, the OTA (Swanson, 1988a) and Lobao (1990) studies stated that their aim was to address the limitations of earlier studies. As a consequence, they focused on developing empirical indicators in accordance with their conceptualization of farm structure, Lobao (1990) through the use of Wimberley's (1986, 1987) indicators and the OTA studies through attention to specific regional patterns. Both sets of studies examined non-linear relationships under the assumption that the effects of moderate-size, family-operated farms may vary from those of larger and smaller farms. Non-farm economic structure was controlled in the OTA studies by indicators such as the percentage of the population employed in services and manufacturing. Lobao (1990) used segmented economy theory to classify employment into high-wage, low-wage and state sectors and also included an enterprise-size variable. Other non-farm variables known to have important effects on well-being, such as educational levels and ethnicity, were controlled and the net effects of farming versus the non-farm economy were examined.

Farming dependency was employed as a control variable in all these studies. Four of the OTA studies controlled for this contextually by examining counties at different levels of farming dependency (Buttel et al, 1988; Flora and Flora, 1988; MacCannell, 1988; van Es et al, 1988). Lobao (1990) and Skees and Swanson (1988) insert control variables for farming dependency as well as for urban influences.

The studies were premised upon broadening the generalizability of earlier work, geographically and over time. The OTA studies examined the major US agricultural regions while Lobao's (1990) analysis focused on the continental US, major agricultural regions, and select subregions. Cross-sectional and longitudinal relationships were examined, the latter enabling the effects of farm change to be ascertained. Further, the studies recognized the reverse causal relationship – that community changes influence farming.

Finally, the studies go beyond simple empirical replication of the Goldschmidt hypothesis. Their conceptual frameworks build upon political economy and other perspectives in the sociology of agriculture and community development. Lobao's study (1990) addressed theoretically the reasons for inequality across different spatial settings, incorporating structural perspectives from industrial sociology, economic geography and regional science.

With regard to large-scale farming, the OTA studies found negative effects for the California, Arizona, Texas and Florida regions. Effects were mixed for the Great Plains, West and South, where there was some indication that moderate size farms were related to higher well-being. Farm changes had little relationship to well-being in the North-east and Midwest. Lobao's (1990) national findings were that larger, family-labour-dependent units are related to higher well-being over time and cross-sectionally. Smaller family farming was related to poorer conditions, although not necessarily over time. These effects generally held across regions. Nationally, industrialized farming had little effect on well-being cross-sectionally. This varied over time and by region.

In addition to these volumes, other recent studies addressed aspects of the farm well-being relationship. These studies adopted current methodologies, including the use of longitudinal analyses and controls for important non-farm variables (Albrecht, 1992; Gilles and Dalecki, 1988; Lobao and Schulman, 1991). They shared two major foci. Empirically, they were concerned with the context, particularly region, within which relationships occur. From a conceptual-theoretical standpoint, these studies attempted to develop frameworks to understand why farm structure and its effects might vary by geographic context.

The Barnes and Blevins study

This review is not meant to deny that modification and replication of the previous research are not needed. Rather, it is to show that the unique contributions that Barnes and Blevins (1992, p334) purport to make were made years earlier:

> This study examines the relationship between farm structure and well-being. We remedy problems in previous research by carefully selecting our farm structure variables, incorporating indicators of nonfarm sectors, taking into account the extent of each county's farm dependence, and using data on all nonmetropolitan counties.

If these contributions are not original, what does the Barnes and Blevins (1992) article add to the literature? First, they controlled for agricultural dependency in a somewhat different way than previous studies. They used national data and performed analyses for non-metropolitan counties grouped into three levels of dependency. A second difference is their choice of independent variables for non-farm economic structure; they used an earnings rather than an employment measure.

The contributions of the Barnes and Blevins (1992) article thus appear to be largely empirical. It is certainly useful to question the methodology and measures of previous studies – and if the article had been premised on these aims, we would likely have no qualms. However, overlooking the inroads made in the Goldschmidt literature makes the study vulnerable to other problems.

First, unlike other recent studies, Barnes and Blevins (1992) cannot test whether changes in farming are related to poorer well-being over time. Their analysis was cross-sectional rather than longitudinal. Since their focus seemed to be large-scale, hired-labour-dependent farming, this is particularly critical. There is some evidence that the negative effects of such farming, while small, are observable over time not cross-sectionally (Lobao, 1990; see also Gilles and Dalecki, 1988). Second, Barnes and Blevins (1992) failed to control for key non-farm variables, such as ethnicity, unemployment levels and education. These variables are well-known correlates of poverty and median family income and tend to be associated with economic structure (e.g. industrialized farming areas tend to have higher non-white populations). Relatedly, they do not control for the region of the country nor acknowledge how this fits into their findings. For example, Barnes and Blevins (1992) found that the percentage of the population hired as farm labour and large farms are inversely related to poverty for farming-dependent counties. Such counties, however, are located mainly in the Great Plains and Corn Belt (Reimund and Brooks, 1990) where analysts have found less detrimental and sometimes positive impacts of industrialized farming (Flora and Flora, 1988; Lobao and Schulman, 1991; van Es et al, 1988). Midwestern social structural attributes and the greater presence of resident owners (rather than absentee landlords) of large farms have been given as possible explanations for these findings, which conflict with the traditional Goldschmidt hypothesis (Lobao and Schulman, 1991; Swanson, 1990).

At face value, the methodology used by Barnes and Blevins' (1992) study is inadequate for assessing the relationship between farm structure and community well-being. Moreover, one would expect that the analysis would be tilted toward finding no negative impacts of large-scale or hired-labour-dependent farming, given its cross-sectional approach, regional bias, and lack of additional control variables. Now perhaps Barnes and Blevins did address these problems in an earlier but unreported analysis and perhaps their findings still stand. If this is the case, concern with such methodological issues has been so long-standing in the literature that the method for dealing with them should have been discussed.

The study also raises other questions about the analysis and the authors' intent. Barnes and Blevins (1992, p336) assert that they 'wanted to analyze the potentially different impact of farm structure on the well-being of counties with different levels of farm dependency'. If this is the intent, then interaction terms (for farm dependency by the farm structure independent variables) should have been inserted directly into the regression model. A related point concerns their statement that 'there is an important interaction effect between the farm and nonfarm variables' and that this effect can be discerned by examining the amount of variance explained (Barnes and Blevins, 1992, p345). However, interaction does not refer to the increase in an *R*-squared coefficient that one gets by adding additional variables. Interaction effects refer to the idea that the effect of independent variable A on the dependent variable is conditioned by the level of independent variable B. Interaction effects must be tested by adding an interaction term (A × B) and testing for its significance. If the authors believe that there are important interactions in their data, then these should have been tested for appropriately.

In addition to raising methodological questions, there is a more significant problem. The Barnes and Blevins (1992) article does not advance the literature conceptually but rather reflects the earlier, post-war period of research in which analysts simply replicated the Goldschmidt hypothesis. There is little attempt to explain from a theoretical standpoint why the effects of farm structure may vary in different geographic contexts or to extend the topic through adding new literature and insights. Arguments about the need to incorporate non-farm structure and to control for farming dependency are repeated from prior work. Thus, no new ground is covered and research slips back to an earlier era.

New Directions: Whither the Goldschmidt Hypothesis?

Goldschmidt's (1978a) work has achieved a status seldom accorded other research. The case study of Arvin and Dinuba has taken on mythic proportions and some studies treat the relationships as if set in stone. Over a decade of research has shown, however, that Goldschmidt's hypothesis cannot be applied unconditionally across different regional and historical settings. It is now also well-known that researchers must acknowledge how the structure of agriculture and the factors that shape well-being have changed over time. The literature in the Goldschmidt tradition appears to be exhausting itself, particularly if one looks at the proliferation of studies and regional research projects in the late 1970s–early 1980s as compared with the present. Rather than resurrecting old debates, researchers should focus on the more significant questions raised by the Goldschmidt (1978a) study. How are economy and society linked? What do changes in the economy mean for rural areas and people? What type of agricultural system best serves social needs? These questions cannot be answered by focusing on monolithic generalizations assumed to exist in all times and places.

There are a number of directions in which future studies concerned with the impacts of farming might proceed. Analysts have already carved out some of these directions more deeply than others. The first is the continued elaboration of the relationship between farming structure and community well-being. Case studies to delineate the routes by which farming affects communities are still needed. A thorough analysis of this issue is generally not possible through the use of conventional county-level secondary data. For example, large-scale farming may impact communities through the labour force it utilizes, owners' control of local politics, land and water rights, and environmental regulations. Focusing on the spatial context within which relationships occur and documenting theoretically the reasons for these are another route. Analysts have stressed both environment and social structure as explanations for regional and other geographic differences but further work remains.

A second direction would be to incorporate a focus on farm structure more fully into the general issue of rural and global restructuring (Marsden et al, 1990). This would involve the use of literature from industrial sociology, economic geography and regional science dealing with economic structure and geographic space. This literature covers topics such as the spatial division of labour or distribution of economic activity, labour-market and locality research, and industrial location theory. It could provide insights about the spatial patterns, dynamics, and impacts of farming and how farming articulates with the non-farm economy. Farming would be treated less as a unique case in community economic development, its analysis subject to the principles that govern other industries in the formal and informal economy.

Another direction is to continue to connect changes in farming to broader agricultural issues and to impacts beyond the locality, as others have argued (Friedland, 1982, 1989; Friedland et al, 1981). In the first instance, how farming is affected by and utilized in globalization processes shaping agriculture is a timely issue. While researchers have long pursued the environmental, food safety and health-related impacts of farm production, much of the literature remains dominated by non-social scientists.

Finally, the evolution of the Goldschmidt debate itself is still a largely unexplored topic, barely covered in this commentary. A more systematic review of the Goldschmidt literature, particularly from a historical and sociology of knowledge standpoint, would illuminate not only this particular genre of studies but rural sociology as a discipline.

Social Connectedness in Marginal Rural China: The Case of Farmer Innovation Circles in Zhidan, North Shaanxi

Wu Bin and Jules Pretty

Introduction

Despite remarkable recent achievements, rural poverty elimination still presents significant challenges in China (Khan, 1998; Piazza and Liang, 1998; Yao, 2000; World Bank, 2001). Poverty is particularly endemic in marginal areas characterized by problems of both poor asset stock (natural, physical and human capital) and the scarcity of capital inflows (e.g. financial, technology, information and talent) (Shen et al, 1992; Zhu and Jiang, 1996; Jalan and Ravallion, 1997; Rahman and Riskin, 1998; Rozelle et al, 1998; Yang, 2003). If there is to be a breakthrough for rural development in these marginal areas, then agricultural innovation is widely viewed as a necessary condition (CAS, 1991; Yao et al, 1996; Fan and Pardey, 1997; Yonggong, 1998; Zhuge and Tisdell, 1999). Yet technological innovation is constrained by the difficulties that formal agricultural extension finds in reaching remote and inaccessible areas (Delmen, 1991; Shi, 2001; Wu, 2003). This lack of communication and interaction between farmers and agricultural professionals constrains the fit between supply of new technologies and the pressing needs of the rural poor (Liu, 2000).

Hitherto, most attention has been paid to improvement of development assistance and agricultural extension, rather than assessing the development potential of marginal communities themselves. These are dynamic and diverse, with great potential for innovation in both technologies and self-organization (Pretty, 2002; Uphoff, 2002). This paper explores the implications of farmer innovation and local self-organization for government and agricultural professionals. The focus is

Reprinted from *Agriculture and Human Values* 21, 2004, 81–92, Social connectedness in marginal rural China: The case of farmer innovation circles in Zhidan, North Shaanxi, Wu B and Pretty J N.

on rural communities of north Shaanxi of China and the phenomenon of 'farmer innovation circles' (FIC). These are informal social systems used by the rural poor for their own technology development and cooperation. We explain the theoretical background and analytical framework, then summarize the features of Zhidan County and the methodology used. We then analyse the distribution of household innovative capacity, and then link this to wider innovation circles and household incomes. We then show how innovative capacity is accumulated in a case study, and conclude with reflections on the development and policy implications.

Social Connectedness and Farmer Innovation Circles: A Conceptual Framework

With constraints on local asset stock and access to external resources (finance, technology, information), rural communities in marginal areas face significant challenges to secure and sustain their livelihoods. It is now widely accepted that livelihoods derive goods and services from five assets (comprising natural, social, human, physical and financial capital), and such livelihoods can be said to be sustainable when they can cope with and recover from stresses and shocks and maintain or enhance assets and capabilities, whilst not undermining the natural resource base (Carney, 1998). In marginal areas, the shortage of other formal assets means that a key resource available for the poor is social capital – their capacity to work together to cope with common challenges (Coleman, 1988; Putnam et al, 1993; Flora, 1998; Krishna, 2002; Uphoff, 2002). Social capital can be identified as having four core aspects: (i) relations of trust, (ii) reciprocity and exchanges, (iii) common rules, norms and sanctions, and (iv) connectedness in networks and groups (Pretty and Ward, 2001).

The idea of social connectedness suggests a means to assess social capital and its effects on rural livelihoods (Chang and Feuchtwang, 1996; Putnam, 2001; Krishna, 2002). Social capital can be enhanced with increasing social connectedness, such as a growing frequency of communication and mutual support between households, or created, such as by the establishment of new cooperatives or groups. It may also be diminished through the expansion of individualism and conflict. Equally, it cannot be assumed that social capital is always good for all members of communities (Knight, 1992; Fine, 1998; Woolcock, 1998). An important, though often neglected, aspect of social capital is the way it relates to innovation. In many contexts, there is a need to focus on the types of social capital that enhance capacity to solve problems rather than just focus on overall quantitative increases or decreases in social capital (Flora and Flora, 1993; Pretty, 2002). In the face of high uncertainty, the capacity of people in marginal areas to innovate and adapt technologies and practices becomes vital for rural development. In vulnerable and marginal communities, this need for innovation is even stronger (Chambers et al, 1989). An important development question centres on whether forms of social capital can be accumulated to enhance such innovation (Cernea, 1987; Pretty, 1995; Röling and Wagemakers, 1997; Pretty, 2002; Uphoff, 2002).

The importance of social capital for the rural poor in marginal areas can be assessed by studying the relationship between social connectedness and household innovative capacity. The lack of external resources and support means that the poor have to learn and diffuse new technologies by themselves. Here we use the term 'farmer innovation circle' (FIC) to refer to the informal networks, groups or mechanisms used by farmers for their own technology development and sharing. We therefore pose three questions. Is there any evidence to indicate the existence and successful functioning of FICs? If so, how effective are they in marginal areas in increasing incomes for the rural poor? And finally, by what patterns and mechanisms do the rural poor establish, maintain and develop FICs to enhance their innovative capacity?

Zhidan County: Background and survey methodology

A rural survey was conducted in north Shaanxi in the summer of 1997. Located at the heart of the Loess Plateau, Zhidan is one the most ecologically fragile counties of north China. Of its 3781km^2 land, three-quarters are affected by serious soil erosion. In addition, Zhidan has the status of a 'nationally-assigned poor county', which means it shares many common features with other 'poor counties' in rural China. Table 15.1 highlights the several features of Zhidan's rural economy.

Zhidan is an 'agricultural county' where some 90 per cent of its population are dependent upon agricultural economy, which is similar to most of Shaanxi's 102 counties. Although Zhidan was one of 50 'nationally-assigned poor counties' within Shaanxi province, its rural income per capita and rural incidence are close to the provincial average. Regarding sustainable rural livelihoods, Zhidan has an advantage in grain production where the annual grain production per capita was 386kg/person, 54kg higher than the provincial average. But the average production per area of farmland in Zhidan was about one-fifth of the provincial average,

Table 15.1 *Secondary data on study area*

Indicators	*Zhidan County*	*Shaanxi Province*
Rural share of the total population (%)	88	86
Rural net income per capita (yuan/person)	816	850
Rural poverty incidence (% of households)	20	18.5
Annual grain production (kg/person)	386	332
Annual grain production (kg/mu)	23	93
Cultivation of steep slopes (% of farmland over 25^o to total farmland)	29	16
Inorganic fertilizer use (kg/person)	222	446
Power of farming machine (kw/person)	1.7	3.4

Source: National Bureau of Statistics (2000), Shaanxi's Agricultural Department (1996) Shaanxi's Agricultural Regionalization Office (1989). Data refer to various years in the 1990s mainly because of poor quality farmland, cultivation on steep slopes and the low use of external production factors (e.g. fertilizers, farm machinery).

Zhidan County can be divided into four main regions. Generally, the north is high in elevation (1300–1741m), with extensive gullies and poor vegetation. In the south, altitude (1093–1680m) and population density are lower, with dense woodland cover. Between them, middle Zhidan is relatively gentle in topography, with dense population and good agricultural facilities. The eastern part is the county's political and economic centre with good transport, an emerging local oil industry and expanding urban markets. By contrast, the western part shares similar agricultural resource conditions but has few non-farm economic opportunities. One township in each of the north, west and east regions was selected for investigation. The south was not sampled for two reasons – it is part of a national forest zone in the Loess Plateau, with a quite different landscape from the rest of Zhidan, and a state-owned company manages forestry and grazing resources.

Table 15.2 gives the secondary data for the three selected townships. Zhidan is heterogeneous in terms of resource endowment and development opportunities. Among three sample townships, for instance, the length of road in Zhonghe is longer than the sum of other two townships, indicating an uneven distribution of rural infrastructure. Whilst the average value of Zhidan's rural net income was close to the provincial average, Zhifang, the poorest township of Zhidan, has only two-thirds of the county's average. It is not surprising that according to the Zhidan Poverty Reduction Office, the majority of the rural poor in Zhidan are concentrated in its north and west zones, and in particular these remote and high-mountain villages are characterized by long distances to main roads and markets, poor vehicle access and a high rate of inattendance at school. Unlike other 'poor areas' in Shaanxi, grain shortages are not significant for Zhidan at the aggregate level.

The field survey consisted of three elements: participatory observation and village comparison, household questionnaire survey, and mini case studies. All administrative villages in each sampled township were divided into three groups according to rural net income in the previous year, and one of each group was selected as a sample administrative village. All sub-villages (or natural village or

Grain production (kg/person)	465	311	395	393

Sources: Zhidan Planning and Statistical Office (1996), Zhidan Agricultural Survey Office 'villager group' in official terms, village hereafter) were included in the survey. In order to overcome standard geographic biases, a 'barefoot' strategy (eating and living with local people, walking on foot instead of taking vehicles) was adopted by the survey team, which comprised the first author, two local assistants, and 1–2 farmers. A standard format, 'village information sheet' was employed for the purposes of participatory observation and village comparison, which covers the baseline information of each village, including: geographical location and topographic features, population and demographic information, distribution and utilization of land resources, village history and social structure. During the period of on-foot movement from one village to another, the survey team cross-checked official statistical data, and developed hypotheses and questions for later village discussions. On arrival in the village, a group meeting was held to complete the 'village information sheet', to examine and improve research hypotheses, and to explore key issues raised by local people. In total, 50 villages within nine administrative villages were visited and village information sheets completed for each.

Whilst village surveys were concentrated on the environment and resource management issues, the household questionnaire survey provided a means to collect the information on rural livelihood systems, to measure the inputs and outputs of household production systems, and also to quantify the scale and structure of social networks. Besides the detailed information on household revenues and expenditure, special attention in the household questionnaire surveys was placed on understanding links between kinship, relatives and village residents, the closeness of households and the relations of trust and the capacity for people to ask for help without worrying about refusal. It also focused on production and technology issues, and who households usually consult – with a focus on channels or sources for households to learn about technology information and who influences family decisions on adoption. Following a standard process, one in five village households was selected by a systematic random method.

Mini case studies were also used during or after the period of village surveys to develop a more detailed picture of farmer innovation and organization practices. As a result, a total of ten case studies were analysed, covering a range of themes from the adoption of greenhouses for vegetables, the invention of rainfall collecting system, reform in rural property system to links with agricultural extension systems.

Local Conditions and Household Innovative Capacity

All 50 sample villages have been allocated to one of three categories (valley, middle and remote) according to a variety of geographic and resource endowment characteristics (Table 15.3). This shows that regional divisions based upon administrative hierarchy underestimates the complexity of rural environments because the differences between the valley and remote villages is large. Some administrative villages contain all three types of village (valley, middle and remote),

Table 15.3 *Division of sample villages and resource endowments*

Village category	*Valley*	*Middle*	*Remote*
Average altitude (m)	1260	1370	1500
Farmland per household (mu)	5mu, irrigated	3mu, terraces	2mu, terraces
Road access	main road	simple vehicle road	No road likely
Electricity power connection	Yes	Ready soon	None
Drinking water source	Within village	Nearby village	Distance (>1.5km)
Distance to main road (km)	0	4	8
Distance to local market (km)	5	8	18
Village size (household)	29	20	14
Net income per capita (yuan/person)	1318	740	578

Source: Data are derived from survey of 50 villages (5 valley, 18 middle, 27 remote)

whilst others have only middle and remote villages. Thus comparisons at township or administrative village levels may not accurately reflect the particular issues facing these remote villages.

Our survey showed that valley villages had more opportunities to access inward investment (e.g. the re-establishment of irrigation systems in recent years) than remote and middle villages. Households in valley villages were predominated by cash crops and non-farming activities, whilst the main sources of household income in the remote villages were from the traditional grains and small livestock. As the middle villages are closer to remote villages in terms of resource conditions and development patterns, we combined their data to compare with the distinctly different context of valley villages.

The questionnaire survey was used to measure three aspects of household innovative capacity in terms of production technologies: the use of production inputs, the structure of household production revenues and level of household net income per capita. By contrast to traditional farming system (no or low production inputs, heavily dependency on grain and sheep, and low economic returns), these criteria provide a set of the objective indicators to recognize the different capacity of household technology learning and adoption. Giving a range of scores from 1 (low), 2 (medium) to 3 (high) to assess household use of production inputs and structure (which refers to the share of new products in household cash revenues) respectively, each household was allocated a total score for innovative capacity. As a result, Table 15.4 shows a range of the total scores in the left column from the minimum of 2 to a maximum of 6. Combining total scores vertically with net income levels horizontally, all sample households can be divided into three groups from bottom left to top right, resulting in three levels of household innovation capacity (HIC). Adopting an assessment panel shown in Table 15.4, all households were graded into three groups for HIC: high, medium and low.

Table 15.4 *Division of household innovative capacity by score and income (number of households)*

Total HIC score	*Income (yuan per person)*				*Households in each HIC class*
	<300	*300–699*	*700–999*	*>=1000*	
6	0	*3*	**9**	**15**	**27**
5	0	*9*	*3*	**4**	**16**
4	**10**	*11*	*9*	**13**	**43**
3	**8**	**17**	*3*	*4*	**32**
2	**10**	**19**	*1*	*1*	**31**

Households with high innovative capacity are those with the capacity to seek, adopt or develop a new production technology or practice by themselves. By contrast, those with low innovative capacity are unlikely to adopt innovations unless major barriers (e.g. information, credit or selling risk) are removed. Not surprisingly, over three-quarters of households in valley villages fell into the category of high HIC, whilst 60 per cent of those in remote villages were in the low category. Some 30 per cent of households in the middle villages were high and 42 per cent low in the HIC assessment.

To examine the features of the HIC and the impacts of the local resource environments, all households in middle and remote villages were compared based upon the division of their HIC. Samples in valley villages are taken out from the comparison in order to reduce the impacts from predominant resource factors (access to main roads, irrigated land, electricity and TV connection). Table 15.5 highlights

Table 15.5 *Features of the levels of HIC and relevant factors in marginal areas of Zhidan*

Category	*Low HIC*	*Medium HIC*	*High HIC*
No. households	64	39	24
Net income (yuan/person)	336	762	1357
Product inputs (yuan/person)	104	180	193
Proportion of income from new cash crops and non-farm income (%)	18	40	69
Distance to central village (km)	2.0	2.8	1.9
Distance to main road (km)	5.6	7.5	3.9
Education: <=1 ys (%)	42.2	35.9	29.2
2–5 ys (%)	39.1	33.3	20.8
>=6 ys (%)	18.8	30.8	50.0

Note: New cash crops include hybrid seed plantation, greenhouse for vegetables, fruit and herb plantation, and non-farming is derived from wool, blacksmith, bricklayer, tiler, carpenter and various other labour services.

major features and relevant factors influencing the distribution of the HIC in the marginal areas of Zhidan, with households with high HIC having 78 per cent higher income than medium HIC, and 400 per cent higher than low HIC households. In addition, it shows the significant difference of both production input and output structures amongst various groups.

Household Innovation Circles

Despite great variation, we found that all rural households have their own communication networks which comprised village kinship (male line, usually in the same village or distribution in nearby villages), close relatives (mainly extended family in-laws in outside villages), and friends (including close neighbours within villages and friends beyond) (Wu et al, 2002). The components, scale and utility of one household communication network are as follows.

In a remote mountain village (20km from Zhidan county town), with 18 household residents and three extended families, Mr Zhang (37 years old) is head of a household of five persons (his wife, two daughters and one son). He reported that he had four kin in his village including one parent (separated from his household), two married brothers, and his father's brother's son (married as well), which are important for his family in terms of security, emergency aid (borrowing grain and cash) and farming experience (his father). Of the other 13 non-family residents in his village, five were identified by him as close neighbours because they often joined together for labour exchange. In addition, he had six friends living in neighbouring villages, whom he met frequently either on his hill plots or in the township market, in order to discuss a range of issues concerned with production, technology, economy and other topics. In addition, his family benefits from frequent interaction (at least 2–3 times per year) with ten of his 'close relatives' (e.g. parents-in-law, two brothers-in-law, three married sisters) in terms of not only a wide source of outside information but also a potential pool of labour, farming tools and sometimes cash. Beside these close relatives, he had three kin living in the county town, his father's brother and his two sons, one of whom is close to him. As a result, a total of 28 households are members of his household communication network for the purposes of information and technology exchange, together with social support and security.

There were several findings on the relationship between household communication networks (HCN) and their innovation capacity. First, there was no difference between valley, middle and remote villages in terms of the total size of the HCN. This seems to suggest that the HCN itself is not merely owned by marginal people but shared by all rural residents. Second, the number of household kin is not related to the variation of the HIC, which is supported by local opinion that kinship at present is little help for household production and technology learning, but may be useful for livelihood security, particularly in borrowing grain or cash to cope with unexpected events. Finally, in addition to kin living in the same or nearby villages, distant close relatives deliberately also facilitate household technology learning and innovation. The role of these close relatives for household innovation is shown by the case of the wide-furrow plough (*Da Long Gou*)

This is a new sowing technology introduced by the government in the early 1990s for the purpose of increasing grain production in mountainous areas. Compared with local traditional sowing methods, the plough can increase grain productivity per unit of land, but requires specific conditions, including good quality land (on terraces, plains or gently sloping land), access to labour and draft animals, and intensive use of external inputs (fertilizers and plastic sheets). Although the government has employed many measures, including administrative intervention and financial subsidies (low-interest loans) to encourage adoption, we found that by 1997 only 62 per cent of households had adopted the new technology, and that the adoption rate in the low mountain villages was higher (73 per cent) than in the high mountains (57 per cent). The difference in adoption rate can be explained by several factors, particularly access to the innovation because of the typically limited provision of demonstration plots and extension staff in the mountainous villages. HCNs appear to have played a positive role in technology adoption, as evidenced by the following statement from a housewife in a remote village: 'The wide furrow programme has interested this village for many years, but we were uncertain of the technical details and cost–benefits until a relative of mine from a low mountain area came to my plots to put on a demonstration last year. Seeing the good results, all the residents in the village have adopted it this spring.' Farmers do not like to adopt new technologies without the opportunity to subject it to close and personal scrutiny, and so the views of close relatives were critical in encouraging her family and neighbours to adopt.

Compared with traditional kinship and relatives, neighbourhood mutual aid and cooperation appear more important for household technology learning and adoption. One of the important factors driving villagers' interactions is that most households suffer from labour shortages in the busy farming seasons (e.g. at sowing). On average, each household had 2.4 workers and 60mu (4ha) farmland, so it is not easy for them to complete sowing alone in a short period (typically 1–2 weeks, and possibly less given that frequent spring droughts often reduce the window of opportunity to only a few days). To overcome these problems, a common strategy is for several households to exchange labour for collaborative sowing. However, not all households in a village are prepared to exchange their labour (or farm tools) with others. While many households benefit from neighbourly mutual aid, others can find it difficult to complete sowing without their relatives' help.

According to the survey, only 20 per cent of households had sowing machinery whilst 25 per cent either did not have draught cattle or experienced a cattle shortage. Neighbourly mutual aid was thus an important precondition for adopting the new level plough, first extended in Zhidan in the 1980s to replace traditional methods. One of the common strategies popularized in the Loess Plateau is that several neighbours cooperate to complete sowing based upon the principle of 'equal exchange' of labour or between labour and cattle or seeding machines.

Table 15.6 *Average size of household communication network by innovative capacity*

HIC level	*No. of HCN*	*Friendly villagers*	*Close relatives*
Low	25	7	11
Medium	31	10	13
High	34	13	14
Significance	0.016	0.003	0.268

Note: This table is derived from a one-way ANOVA analysis on the household questionnaire survey, with households in valley villages again excluded ($N = 127$).

However, not all households are able to exchange their labour or tools with neighbours. For those with tense relations with neighbours, it was difficult for them to join in cooperative arrangements. Instead, they had to depend on assistance from kin or relatives.

Household communication networks also help to spread ideas and technologies. Apple plantations as a new technology, for example, often spread in those villages where more than two households join together for tree management, mainly to avoid sheep damage and theft of fruit. Of those villages with apple orchards, we found that 36 per cent had two orchards (i.e. two households collaborating) in each village, whilst 41 per cent had more than three households involved.

Table 15.6 shows that there is a relationship between the connectivity of households and their innovation capacity. While the scale and style of rural social communication varies household by household, the results from the analysis of variance indicate that there is a significant relation between household innovative capacity (HIC level in the first column) and the average size of household communication network (second column). As we have indicated, household communication networks comprise many components (kin, close relatives and friendly villagers). Table 15.6 indicates a correlation between the number of friendly villagers and household innovative capacity: the larger the number of the friendly villagers (the third column), the higher the household's HIC. The contribution from close relatives (the right column) to the HIC is weaker. Kinship, another component of the household communication network, is not shown as there was no statistical correlation with household innovative capacity.

These findings are supported by a popular local statement: 'Able men are those who have more social links' (local is called *menlu*). Due to the constraints arising from remoteness and weak formal extension networks, more social connectedness means more opportunities to access scarce resources such as information, technology, financial capital and consultation. The HCNs, however, remain loose networks of social connectedness because many are held together by individual households, and there may not be any linkages between different HCNs.

In addition to these loose HCNs that are shared by all rural households at various scales, a variety of focused technology learning groups also appear important in these marginal areas. Compared with the HCN, those groups are characterized by closer social connectedness, because participants have a clear innovation objective, and tend to share production tools and managerial responsibilities. Many phenomena are addressed by these groups, including collaborative buying, group orchards, tobacco and herb plantations, and joint investment for machinery. Such focused group learning is often driven by a central household who takes charge of innovation initiatives, organization and harmony.

One example is Wang's vegetable production group, which now accounts for about half of the village's vegetable production for the county market. This is one of three informal groups within the village. They are the most successful because Mr Wang was a pioneer in adopting and improving greenhouse techniques for vegetable production, as well as promoting a volunteer organization for innovation diffusion. As a result, his greenhouse has become both a free 'training school' and an 'experimental plot' for new technology, which attracted a large number of his neighbours and outside farmers. During the long and very cold winters, more than 20 people regularly assemble in Mr Wang's house for discussions and celebratory meals. As a result, a stable cooperative relationship has emerged among participants, which Mr. Wang oversees as 'leader', while his greenhouse is referred to as '*xiao tian di*', meaning a small but very convenient place like a warm family.

Not limited to greenhouse or vegetable production, innovation groups are very common for cash cropping which relies on frequent communication, intensive labour and management inputs. However, it would be wrong to assume that all groups are similar to Wang's group. Some innovation groups are dominated by kinship, in which non-family neighbours are absorbed but are distant from group decision making. The next case indicates an important fact: technology diffusion in the marginal areas is not always determined by the factor of 'physical distance' but sometimes by 'social distance', in which social connectedness again plays a key role.

Two remote villages are close to each other (only 3km apart). Village A has a strong advantage in apple orchards, as all residents have established their own orchard to share knowledge from an expert living in the same village. By contrast, the neighbouring village B had just begun to develop orchards (three households only). Surprisingly, the technical sources in village B were not from nearby village A, but from a distant village C in another township (10km away). This inefficient technology transfer was mainly because of two factors: (i) the scale demand for services from villagers – seldom would a graft technician go to a village if the scale of the orchard was too small (less than 5mu); (ii) the price of the graft service – the normal price of 6 *yuan* per tree was too expensive for most of the farmers in Village B. Village B might not have adopted apples had not a farmer's relative (brother-in-law) resident in village C offered a cheap service (only 2 *yuan* per tree).

Several conclusions can be drawn from the field findings. First, the physical environment influences but is not the sole determinant of household innovation capacity. Beyond the conventional extension system, there are many types of farmer innovation circles existing in marginal areas, through which the poor join together to learn, diffuse and share new technologies. However, the role of such social connectedness should not be idealized nor overstated. Second, social connectedness is not abstract but has roots in the daily life of farmers. Despite great variations in terms of 'organizational' formats, it can be identified and measured through farmer communication networks comprising kinship and neighbourhoods within villages, and close relatives and friendship outside of village. It is these networks that provide a fundamental rationale for farmer innovation and self-organization in marginal areas of Zhidan county. The larger the network, the greater the innovation.

The Case Study of Taoliwa – an 'Evergreen' Village

Farmer innovation circles (FIC) as a form of social capital span a spectrum from loose and general-purposive social communication to more focused and specialized groups. By accumulating and enhancing social connectedness, there is a possibility of 'organizational innovation' leading to a scaling-up of the innovative group or emergence of new higher-level organizations. Deforestation is a serious challenge for the Loess Plateau. Amongst the bare mountains, there are, however, some 'green islands' of villages surrounded by meadows and trees. In these villages, the high income levels and positive mental attitudes are evident. In order to address why these 'green islands' emerge, we used case studies to provide further insights into how the social connectedness can be accumulated and upgraded, leading to further enhancement of household innovative capacity. This section focuses on one of the ten case studies conducted during the field survey.

Taoliwa (meaning a convenient place producing pear and peach), is a remote mountainous village on the border of north-west Zhidan. Of 17 households, all belong to descendants (11–13th generation) of the eighth Liu's generation, since their ancestor moved into the village from a neighbouring province some 400 years ago. Despite many periods of social upheaval in the 20th century, the Liu's clan still kept a comprehensive record of their clan history. Among 69 close kin and relatives listed in their clan book, the majority are distant urban residents, some of whom live in the cities of Beijing, Xian and Lanzhou. They are proud that a famous Kuomintang general in the 1920–1930s, the tenth generation of the Liu clan, was born and buried in this village.

Similar to elsewhere in Zhidan, some two-thirds of the village land had been covered by forest, until the middle of the 1930s, when large-scale deforestation began. Deforestation was further exacerbated during the period of collectivization, the 'Great Leap Forward' in the late 1950s, and the 'cultural revolution' (1966–1976) in particular, when the village was identified as an 'object of dictatorship' due to General Liu's Kuomintang history. In addition, the continuous growth of population and cultivation was an important factor contributing to deforestation. In particular, the rural reforms of the early 1980s provided a strong stimulus for over-cultivation, when the area of cultivated land reached a peak of 1100mu in 1984, nearly 40 per cent more than that in 1980. By the middle of the 1980s, while the village food needs were met, forest resources in the Taoliwa had been exhausted and the shortage of firewood became a critical constraint.

To overcome this problem, a collaborative afforestation project was initiated. All residents shared a common idea: if the village were to survive and develop, all households should share responsibility for tree plantation and management. Without changing the nature of the household responsibility system, they reached an agreement on local rules and sanctions, which set out that there would be collective planning of tree plantations with all households participating in decision making; each household would be responsible for its own tree seed selection, plantation and management; responsibility for woodland protection would be shared by all residents; a security coordinator would be appointed to harmonize woodland management between households; and strict punishments would be enacted if livestock entered the woodland.

Close unity and cooperation among villagers is vital if young trees are to be protected from attack by sheep and goats. Indeed, if the village's own sheep could not be prevented from entering the afforested land, it soon follows that flocks of sheep from neighbouring villages would also enter. Due to strict management regulations, many sheep owners in the village have indeed been fined, which has increased the deterrent on outside free-riders. Successful management, in turn, encouraged villagers to make continuous efforts in afforestation year by year. By 1997, all four hills of the village were covered by trees, and the area of forest has expanded to 1000mu or nearly 60mu per household, more than 10 times the per capita county average. The benefits of tree planting go beyond firewood, as they have also become an important source of household income through construction timber and fruit trees.

Successful afforestation has provoked agricultural change too, including a transformation of more than 200mu of over-cultivated farmland to firewood land and fruit orchards; a 400mu planted grassland to secure fodder supply; and development planning of commercial pig, oxen and fish breeding for the purposes of both cash generation and organic manure supply. Indeed, the demand for agricultural innovation was so strong that the village representatives have visited the county town to seek new technologies (e.g. level plough and wide furrow, new seeds of grain crops and trees), which at first surprised government officers and professionals because this so seldom occurs. Cooperation has also extended to infrastructure, including the construction of a 4km local road connecting to the main road, access to the outside electricity network, and a central system of water supply for domestic use and animal breeding.

At first sight, it is surprising that so many achievements have been made by farmers themselves, in contrast with the typically short-life or expensive 'experimental', 'demonstration' and 'model' projects funded by governments in the poor areas. The success in Taoliwa would be difficult to understand without uncovering the organizational process. The idea of cooperative afforestation and sustainable development in Taoliwa was originated by an urban kin, the son of General Liu. As an engineer in a state oil company (about 200km away from the village), Mr Liu was persecuted and forced to return to the village during the period of the 'cultural revolution' (1966–1976), owing to his father's history. It provided a unique opportunity for him to gain an in-depth understanding of rural poverty and development. Although his political reputation and position recovered in 1979, he kept close contact with his village, visiting every year. He came to stress the following opinions to his rural kin and neighbours:

> The village's environmental and development issues [e.g. deforestation, inaccessibility to a road] will not be solved if we wait for the government. Rather than be dependent on external assistance, it would be better if all villagers were united and cooperated to open a 'green account' for afforestation and pasture plantation. The significance of cooperative afforestation is not only to provide a sustainable treasure for our descendants, but, if it succeeds, it will offer a novel path for our neighbouring villages and even Zhidan county as a whole – that is, close unity and cooperation rather than the current individualist development will lead to a sustainable future.

Gradually, this idea was shared and supported by all villagers, and the first plan for a firewood plantation emerged at a village meeting chaired by him. Based upon the success of afforestation, a long-term strategy of agricultural innovation and village development was discussed and approved by all villagers in the early 1990s, which then became the blueprint for village development and cooperation. Besides designing the plan, his particular contribution was the establishment and development of a cooperative mechanism, by which all issues related to inter-household relationships and village development are discussed and negotiated in public meetings among all households. Following Mr Liu's idea, a leading core group of three middle-aged farmers has taken charge of organizing, coordinating and harmonizing all households to implement the blueprint.

To improve rural infrastructure, Mr Liu returned to the village to design and initiate a 4km length of vehicle-suitable road, just after he retired in 1993. Without exogenous funding, he contributed 3000 *yuan* from his personal savings and wrote letters to all urban kin nationwide for further donations. Though he died in the period of road construction that winter, Mr Liu's death did not halt the progress of proposed projects, but encouraged villagers to strengthen their unity and cooperation. Learning from Mr. Liu, more urban kin (including his son) have participated in their home village reconstruction, and 'building an evergreen home village' (villagers' phrase) has become a common objective shared by both villagers and their urban kin.

Despite its uniqueness, this case does contain some common elements contributing to the establishment, maintenance and development of community innovations. The historic heritage of the Liu's clan was an advantage, as descendants in the village could reorganize themselves to address ecological degradation and firewood shortages. However, without the spark provided by Mr Liu, these ecological pressures might not have led to innovative organization. An 'opinion leader', or 'innovative core', is thus an important element to drive such collaborative action. Under the household responsibility system in rural China, cooperative consciousness as a core of social capital is particularly important, and provided a sound basis for Taoliwa's people to break through the constraints of narrow individual interests, and to form and maintain a new development dynamic instead. Without returning to the abandoned and formal 'collective system', Taoliwa has developed a new form of collective action. Finally, all these elements were integrated into an 'innovation network' comprising village residents, farmers in nearby villages and urban relatives, leading to an enhancement of village innovation capacity, with a spreading impact on nearby villages.

There are also important generalizable lessons from this specific case of social connectedness in Taoliwa. First, development in the village did not stop after Mr Liu died, which indicates that a more distributed network is driving sustainable development rather than just one person. Second, Taoliwa's experience was not limited within the village but had spread to a number of neighbouring villages. Reflecting the popularity of Taoliwa's experience, the head of Taoliwa was recommended and elected by the residents as director of the administrative village commission. Finally, Taoliwa's experience seems to suggests that as part of traditional culture, the natural links between urban residents and their rural relatives offer another route for rural economic development and technological innovation.

Enhancing Social Connectedness

Compared with other regions, social capital is more important to the marginal areas of China where unfavourable geographic and resource environments constrain the inflows of external capital and knowledge. The importance of social connectedness for the sustainable rural livelihoods in the marginal areas of China has been illustrated through the phenomenon of farmer innovation circles (FIC). Organizational patterns at various levels from household communication networks, inter-household technology learning groups and inter-village innovative links have a positive effect on agricultural and natural resource innovation, which in turn improves rural incomes.

However, it would be romantic to say that enhancing social connectedness by itself necessarily leads to sustainable rural livelihoods as social capital is merely one of many elements affecting local livelihoods. Nor is it true that the FIC alone can meet the needs of farmers entirely without external capital and assistance. Whilst the benefits of external intervention should not be underestimated, top-down development might be neither successful nor sustainable unless the innovative potential and intrinsic dynamics among the poor are fully recognized and developed. If there is to be sustainable development in the marginal areas of China, then there will clearly need to be closer communication and interaction between agricultural professionals and rural communities.

Ecological Design and Education

David W. Orr

Ask the animals, and they will teach you; the birds of the air, and they will tell you; ask the plants of the earth, and they will teach you; and the fish of the sea will declare to you.

Job: 7–9

When you build a thing you cannot merely build that thing in isolation, but must also repair the world around it, and within it so that the larger world at that one place becomes more coherent and more whole; and the thing which you make takes its place in the web of nature as you make it.

Christopher Alexander

Background

Imagine living in a random world without order in which no rules applied, and effects followed no discernible pattern of cause. Such a world would be alien to intelligence, morality and foresight, governed instead by caprice and whimsy, which is to say that it would be a kind of Hell. Design presumes, on the contrary, that matter is ordered and that order matters. But to the questions of exactly what is ordered and how there is no one answer. The more we know, the more mysterious the world appears to be. Beyond the regularities of changing seasons, birth and death, the world that we experience is often chaotic and violent governed as much by fate as by foresight. But even that awareness fuels the effort to discover larger patterns, mastery of which will permit us to establish safe haven or, for some, heaven on earth. For the builders of megalithic monuments like Stonehenge, the clues to order lay in the observed regularities of the night sky and the movements of the sun, moon, and stars. The Greeks, believers in the possibility of reason, discovered geometrical proportions and mathematical harmony in the world. Some believed that cultivation of reason might lead to societies in which reasonable men might collaborate to manage public affairs democratically, yet another level of harmony. For the ancient Jews, the basis of order was otherworldly, a moral order evident in the Laws God delivered to Moses. For the builders of the great cathedrals, that belief was extended into architectural form blending Greek geometry with Judeo-Christian theology in service to the idea that inspired humans could design so artfully as to create sacred spaces that were a portion of heaven on earth.

The fourth great design revolution, built on modern science, presumed a more remote God who had once created a clockwork universe and had the good sense thereafter not to meddle with it. Isaac Newton deciphered the scientific laws God had presumably used and rendered these into the metaphor of a cosmic machine. Adam Smith took that metaphor to describe our tendency to truck and barter as the working out of an invisible hand administering the laws of supply and demand in a mechanistic world. In the fourth revolution, the economy of Adam Smith is the ultimate machine, godlike in its ability to sift order from the chaos of individual self-interest. We continue to live in that faith, now extended to a further abstraction called the global economy.

Each of the design revolutions in some degree persists like geologic layers. Unlike the scientific revolutions described by Thomas Kuhn in which one paradigm overthrows another, less adequate, our sense of order is a kind of lamination in which earlier thinking persists whether in science, social structures, language or even commonplace superstitions. Each transformation in our understanding of how to make the human presence on Earth surrendered in due course to time, human frailty, and their particular flaws, but did not thereby disappear. The megalithic belief in a larger order evident in the rising and setting of the sun, lunar cycles, and movements of the stars survives in the belief that patterns of ecology represent a larger ordering applicable to human systems. So too, the belief that human reason might yet bring order from unreason and caprice. The Greek experiment in rationality survived and flourished in the Christian era as part of what Arthur O. Lovejoy once described as 'the great chain of being' (1936/1974). If humans had the capacity of reason, might they not also discern the very mind of God. The neo-platonism of the medieval world, in Lovejoy's words, 'rested at bottom upon a faith … that the universe is a rational order … a coherent, luminous, intellectually secure and dependable world, in which the mind of man could go about its business of seeking an understanding of things in full confidence' (Lovejoy, 1936, pp327–328). Faith in a rational order and the powers of rationality survives into our time, magnified by the Enlightenment of the 18th century into the creed of inevitable progress. The faith of the medieval churchmen survives not just in the millennarian assumptions of nearly every ideological movement, but in the belief that what we made on Earth ought to reflect higher obligations than those of self-interest. That, too, is an echo of the ancient belief in a divine order that would lead to a final triumph of right.

The increasingly homogeneous industrial civilization that now stretches around the Earth is the signature accomplishment of the fourth revolution, but its future is troubled for reasons that any moderately well-informed high school student could recite. Its prospects are clouded, first, because it is inflicting a rising level of ecological damage evident as impaired ecological functions, the loss of biological diversity, mutilated ecosystems, spreading blight, pollution and climate change. For the scientists who study Earth processes and ecology the facts are well-known. Due to the loss of habitat and pollution, the number of species on Earth will decline by a quarter to one-third in this century. The carbon content of the atmosphere has increased by more than a third from its pre-industrial level of 280ppm and is rising at a rate now of over 2ppm per year, a harbinger of worse to come. The human population has increased six-fold in the last two centuries and will grow to 8 or 9 billion. The number of large predatory fish in the oceans has decreased by 90 per cent. Worldwide soil loss is estimated to be 20–25 billion tonnes per year. Forests, roughly the size of Scotland, are disappearing each year. Within a few years or maybe in a decade or two, we will reach the peak of the era of cheap oil where supply and demand diverge and start down the backside of the curve. That transition could be the start of an era of bitter geopolitical conflicts. Harvard biologist, Edward O. Wilson refers to the decades ahead as a 'bottleneck', an uncertain passage through constraints caused by the loss of species, climatic change and population growth (Wilson, 2002). The scientific evidence documenting the decline of the vital signs of the Earth is overwhelming, so too the burden of pondering such complicated and dire things which may help to explain the growing popularity of escapism, religious zealotry, hyper-consumption and other modes of denial.

The industrial experiment is failing, too, because of growing inequities and violence. In spite of nearly a century of economic growth, a majority of people on Earth experience life close to the bone. Over 1 billion people live at the edge of starvation in absolute poverty. Their daily reality is hunger, insecurity and hopelessness. At the other end of the spectrum another billion live in affluence and suffer the consequences of having too much. Powered by cheap fossil energy, their world is one of traffic jams, suburban malls, satiation, fashion, fad diets, addiction, boredom, excitement and commercial entertainment. In spite of high rates of economic growth, the trend is toward greater and greater inequity that is leading to a world dominated by a handful of corporations and a few thousand super wealthy. These two worlds appear to be diverging, but in fact their destinies are colliding. Security, once a function of distance and military might, has been radically changed by terrorism and the diffusion of heinous weaponry. National borders no longer provide safety. The powerful and wealthy are vulnerable now precisely because their power and wealth makes them targets for terrorists and malcontents. And ethics, once a matter of individual behaviour, now includes the conduct of whole societies and entire generations whose choices about energy and resource use cast long shadows across the planet and into the far future.

The inability to solve ecological and social problems points to deeper flaws. Like the proverbial fish unaware of the water in which it swims, we, too, have difficulty perceiving fatal flaws in our ideas, paradigms and behaviour that we take for granted until it is too late. In Jared Diamond's words 'human societies and smaller groups may make disastrous decisions for a whole sequence of reasons: failure to anticipate a problem, failure to perceive it once it has arisen, failure to attempt to solve it after it has been perceived, and failure to succeed in attempts to solve it' (Diamond, 2005, p438). In our time the inability to perceive and to solve problems is often related to our faith in technology that leads some to believe that we are masters of nature and smart enough to manage it in perpetuity. That presumption, in turn, rests on an improbably rosy view of human capabilities and the faith, as Robert Sinsheimer (1978) once put it that nature sets no traps for unwary species.

Our optimism is, I think, a product of a particular era in human history shaped by the one-time drawdown of cheap fossil fuels, the 'age of exuberance' in William Catton's words. Our politics, economics, education as well as personal expectations were shaped by the assumption that we had at last solved the age-old problem of energy. Ancient sunlight fuelled rapid economic growth, vastly increased mobility and agricultural productivity, and a level of affluence that our ancestors could not imagine. But it also weakened social cohesion, encouraged over-consumption, polluted our air and water, contaminated our politics, while creating a fragile and temporary energetic basis for the most complex human civilization ever.

Unfortunately, complex societies are vulnerable to breakdown for many reasons. Anthropologist, Joseph Tainter, summarizes these by saying that:

> as stresses necessarily arise, new organizational and economic solutions must be developed, typically at increasing costs and declining marginal return. The marginal return on investment in complexity accordingly deteriorates slowly at first and then accelerates. At this point, a complex society reaches the phase where it becomes increasingly vulnerable to collapse (Tainter, 1988, p195).

In other words, even with foresight we fail to anticipate problems which outrun solutions thereby aggregating into crises, then into a system-wide crisis of crises, the sense of care, always a limited resource, falters, human ingenuity, however considerable, fails, and things come tumbling down (Homer-Dixon, 2000). The story is an old one – lack of vision, the intoxication of power, tragedy, arrogance, stupidity and angry gods.

Toward a Design Science

The fox, it is said, knows many things but the hedgehog knows one big thing. Ecological designers, like the hedgehog, know one big thing – that everything is hitched to everything else as systems within still larger systems and patterns that connect across species, space and time. Ecological design begins in the recognition that the whole is more than the sum of its parts, that unpredictable properties emerge at different scales, and as a result that we live in a world of surprise and mystery. Those who design with nature work in the recognition that the world is one and indivisible, that what goes round comes around, that life is more paradoxical than we can ever know, and that health, healing, wholeness and holy, too, are inseparable. Ecological design is the careful meshing of human purposes with the patterns and flows of the natural world and the study of those patterns to inform human intentions, leaving a margin for error, malfeasance and the unknown. Ecological design requires an efficiency revolution in the use of energy and materials, a transition to renewable energy, changes in land use and community design, the transition to economies that preserve natural capital, and a recalibration of political and legal systems with ecological realities.

The origins of ecological design can be traced back into our prehistoric ancestors' interest in natural regularities of seasons, sun, moon and stars, as well as in the Greek conviction that humans, by the application of reason, could discern the laws of nature. Ecological design also rests on the theological conviction that we are obliged, not merely constrained, to respect larger harmonies and patterns. The Latin root word for the word religion – bind together – and the Greek root for ecology – household management – suggest a deeper compatibility and connection to order. Ecological design, further, builds on the science and technology of the industrial age, but for the purpose of establishing a partnership with nature, not domination. The first models of ecological design can be found in vernacular architecture and the practical arts that are as old as recorded history. It is, accordingly, as much a recovery of old and established knowledge as discovery of anything new. The arts of building, agriculture, forestry, health care and economy were sometimes practised sustainably in cultures that we otherwise might dismiss as primitive. The art of applied wholeness was implicit in social customs such as the observance of the Sabbath and Holy days, and the Jubilee year or the practise of potlatch in which debts were forgiven and wealth was recirculated. It is evident still in all of those various ways by which communities and societies gracefully cultivate the arts of generosity, kindness, prudence, love, humility, compassion, gentleness, forgiveness, gratitude and ecological intelligence.

In its specifically modern form, ecological design has roots in the Romantic rebellion against the more extreme forms of modernism, particularly the belief that humans armed with science and a bit of technology were lords and masters of Creation. Francis Bacon, perhaps the most influential of the architects of modern science, proposed the kind of science that would reveal knowledge by putting nature on the rack and torturing her secrets from her, a view still congenial to some who have learned to say it more correctly. The science that grew from Bacon, Galileo and Descartes overthrew older forms of knowing based on the view that we are participants in the forming of knowledge and that nature is not dead (Merchant, 1982). The result was a science based on the assumptions that we stand apart from nature, that knowledge was to be judged by its usefulness in extending human mastery over nature, and that nature is best understood by reducing it into its components pieces. 'The natural world', in the words of philosopher E. A. Burtt, 'was portrayed as a vast, self-contained mathematical machine, consisting of motions of matter in space and time and man with his purposes, feelings, and secondary qualities was shoved apart as an unimportant spectator' (1954, p104). Our minds are so completely stamped by that particular kind of science that it is difficult to imagine another way to know in which comparably valid knowledge might be derived from different assumptions and something akin to sympathy and a 'feeling for the organism' (Keller, 1983).

Among the dissidents to the directions of modern science, Goethe, best known as the author of *Faust*, stands out among the first theorists and practitioners of the science of wholeness. In contrast to a purely intellectual empiricism, what physicist and philosopher Henri Bortoft calls the 'onlooker consciousness', Goethe stressed the importance of relying on observation beginning with intuition that allowed the object being investigated to speak to the observer. Descartes, in contrast, reportedly began his days in bed by withdrawing his attention from the contaminating influence of his own body and the cares of the world, to engage in deep thinking. He aimed, thereby, to establish the methodology for a science of quantity established by pure thought. Goethe, on the other hand, practised an applied science of wholeness in which 'the organizing idea in cognition comes from the phenomenon itself, instead of from the self-assertive thinking of the investigating scientist' (Bortoft, 1966, p240).

Instead of the intellectual inquisition proposed by Bacon and practised subsequently, Goethe proposed something like a dialogue with nature by which scientists 'offer their thinking to nature so that nature can think in them and the phenomenon disclose itself as idea' (1952, p242). Facilitation of that dialogue required 'training new cognitive capacities' so that Goethean scientists 'far from being onlookers, detached from the phenomenon, or at most manipulating it externally … are engaged with it in a way which entails their own development' (1952, p244). In Bortoft's words, 'the Goethean scientist does not project their thoughts onto nature, but offers their thinking to nature so that nature can think in them and the phenomenon disclose itself as idea', (1955, p242) which requires overcoming a deeply ingrained habit of seeing things as only isolated parts not in their wholeness. The mental leap, as Bortoft notes, is similar to that made by Helen Keller who, blind and deaf, was nonetheless able to wake to what she called the 'light of the world' without any preconceptions or prior metaphoric structure whatsoever. Goethe did not propose to dispense with conventional science, but rather to find another, and complementary, doorway to the realm of knowledge in the belief that Truth is plural, not the monopoly of one method, one approach, one time or one culture.

Implicit in Goethe's mode of science is the old view, still current among some native peoples, that the Earth and its creatures are kin and in some fashion sentient, able to communicate to us, that life comes to us as a gift, and that a spirit of trust, not fear, is essential to knowing anything worth knowing. That message, in Calvin Martin's words 'is riveting … offering a civilization strangled by fear, measuring everything in fear, the chance to love everything' and to rise above 'the armored chauvinism' inherent in a kind of insane quantification (Martin, 1999, pp107, 113). It is, I think, what Albert Einstein meant in saying that:

> A human being is part of a whole, called by us the universe, a part limited in time and space. He experiences himself, his thoughts and feelings, as something separated from the rest – a kind of optical delusion of his consciousness. This delusion is a kind of

> prison for us, restricting us to our personal desires and to affection for a few persons nearest us. Our task must be to free ourselves from this prison by widening our circles of compassion to embrace all living creatures and the whole of nature in its beauty.

Goethe proposed a kind of jailbreak from the prison of Cartesian anthropocentricism and from beliefs that animals and natural systems were fit objects to be manipulated at will. His intellectual heirs include all of those who believe that the whole is more than the sum of its parts, including systems thinkers as diverse as mathematician and philosopher, Alfred North Whitehead, politician and philosopher, Jan Smuts, biologist, Ludwig von Bertalanffy, economist, Kenneth Boulding, and ecologist, Eugene Odum. Goethe's approach continues in the study of non-linear systems in places like the Santa Fe Institute. Biologist, Brian Goodwin for one, calls for a 'science of qualities' that complements and extends existing science (1994, p198). Conventional science, in Goodwin's view, is incapable of describing:

> the rhythms and spatial patterns that emerge during the development of an organism and result in the morphology and behavior that identify it as a member of a particular species … or the emergent qualities that are expressed in biological form are directly linked to the nature of organisms as integrated wholes (1994, pp198–199).

Goodwin, like Goethe, calls for a 'new biology … with a new vision of our relationships with organisms and with nature in general … [one] that emphasizes the wholeness, health, and quality of life that emerge from a deep respect for other beings and their rights to full expression of their natures' (1994, p232). Goodwin, Goethe and other systems scientists aim for a more scientific science, predicated on a rigour commensurate with the fullness of life in its lived context.

While Goethe's scientific work focused on the morphology of plants and the physics of light, D'Arcy Thompson, one of the most unusual polymaths of the 20th century and one who 'stands as the most influential biologist ever left on the fringes of legitimate science' approached design by studying how and why certain forms appeared in nature (Gleick, 1988, p199). Of his *magnum opus On Growth and Form* (1917), Sir Peter Medawar said that it was 'beyond comparison the finest work of literature in all the annals of science that have been recorded in the English tongue' (Gleik, 1988, p200). Thompson seems to have measured everything he encountered, most notably natural forms and the structural features of plants, and animals. In so doing he discovered the patterns by which form arises from physical forces, not just by evolutionary tinkering as proposed by Darwin. Why, for example, does the honeycomb of the bee consist of hexagonal chambers similar to soap bubbles compressed between two glass plates? The answer Thompson discovered was found in the response of materials to physical forces, applicable as well to 'the cornea of the human eye, dry lake beds, and polygons of tundra and ice' (Willis, 1995, p72). Thompson challenged the Darwinian idea that heredity determined all by showing the physical and mechanical forces behind life forms at all levels. His work inspired subsequent work in biomechanics, evolutionary biology, architecture and biomimicry, including that by Paul Grillo, Karl von Frisch and Steven Vogel.

Frisch, for example, explored the ingenuity of animal architecture evolved by birds, mammals, fishes and insects. African termite mounds a dozen feet high, for example, maintain a constant temperature of ~78°F in tropical climates (Frisch, 1974, pp138–149). Nests are ventilated variously by permeable walls that exchange gases and by ventilation shafts opened and closed manually as needed with no other instructions than those given by instinct. Interior ducts move air and gases automatically by convection. The system is so ingeniously designed that chambers deep underground are fed a constant stream of cool, fresh air that rises as it warms before being ventilated to the outside. Termite nests are constructed of materials cemented together with their own excretions, eliminating the problem of waste disposal. Desert termites, with no engineering degrees as far as is known, bore holes to depths of 40 metres below their nests to find sources of water. Beavers construct large dams of 1000 feet or more in length; their houses are insulated to remain warm in sub-zero temperatures. Other animals, less studied, build with comparable skill (see Tsui, 1999, pp86–131). Human ingenuity, considerable as it is, pales before that of many animals that design and build remarkably strong, adaptable and resilient structures without toxic chemicals, machinery, fossil fuels and professional engineers.

The idea that nature is shaped by physical forces as much as by evolution is also evident in the work of Theodor Schwenk who explored the role of water as a shaper of Earth's surfaces and biological systems. Of water Schwenk wrote that:

> In the chemical realm, water lies exactly at the neutral point between acid and alkaline, and is therefore able to serve as the mediator of change in either direction. In fact, water is the instrument of chemical change wherever it occurs in life and nature… In the light-realm, too, water occupies the middle ground between light and darkness. The rainbow, that primal phenomenon of color, makes its shining appearance in and through the agency of water… In the realm of gravity, water counters heaviness with levity; thus, objects immersed in water take on buoyancy… In the heat-realm water takes a middle position between radiation and conduction. It is the greatest heat conveyer in the earth's organism, transporting inconceivable amounts of warmth from hot regions to cooler ones by means of the process known as heat-convection… In the morphological realm, water favors the spherical; we see this in the drop form. Pitting the round against the radial, it calls forth that primal form of life, the spiral… In every area, water assumes the role of mediator. Encompassing both life and death, it constantly wrests the former from the latter. (Schwenk, 1989, p24)

Moving water shapes landscapes. As ice it moulds entire continents. At a micro scale, its movement shapes organs and the tiniest organisms. But at any scale it flows, dissolves, purifies, condenses, floats, washes, conducts and some believe that it even remembers. Our language is brim full of water metaphors and we have streams of thought or dry spells. The brain literally floats on a water cushion. Water in its various metaphors is the heart of our language, religion and philosophy. We are much given to the poetry of water as mists, rain, flows, springs, light reflected, waterfalls, tides, waves, storms. Some of us have been baptized in it. But all of us stand before the mystery that D. H. Lawrence called 'the third thing', by which two atoms of H and one of O become water and no one knows what it is.

'Form patterns', Schwenk wrote, 'such as those appearing in waves with new water constantly flowing through them, picture on the one hand the creation of form and on the other the constant exchange of material in the organic world' (1996, p34). Water is a shaper, but the physics of its movement is also the elementary pattern of larger systems 'depicting in miniature the great starry universe' (1996, p45). Water is the medium by which and through which life is lived. Turbulence in air and water have the same forms and mechanics as vortices whether in the ocean, atmosphere or in space. Sound waves and waves in water operate similarly. Schwenk's great contribution to ecological design, in short, was to introduce water in its fullness as a geologic, biological, somatic and spiritual force, a reminder that we are creatures of water, all of us merely eddies in one great watershed.

The profession of design as a practical art probably begins with the great British and European landscapers such as Capability Brown (1716–1783) famous for developing pastoral vistas for the rich and famous of his day. In our own history the early beginnings of design as applied ecology are apparent in the work of the great landscape architect and creator of Central Park in New York, Frederick Law Olmsted and, later, in that of Jens Jensen, who pioneered the use of native plants in landscape designs in the Midwest. Ian McHarg, a brilliant revolutionary, merged the science of ecology with landscape architecture aiming to create human settlements in which 'man and nature are indivisible, and that survival and health are contingent upon an understanding of nature and her processes' (1969, p27) His students including Pliny Fisk, Carol Franklin and Ann Whiston Spirn continued that vision armed with sophisticated methodological tools of geographic information systems and ecological modelling applicable to broader problems of human ecology.

While the degree of influence varied, many early efforts toward ecological design were inspired by the arts and crafts movement in Britain, particularly the work of William Morris and John Ruskin. In US architecture, for example, Frank Lloyd Wright's attempt to define an 'organic architecture' has clear resonance with the work of Morris and Ruskin as well as the transcendentalism of Ralph Waldo Emerson. Speaking before the Royal Institute of British Architects in 1939, Wright described organic architecture as 'architecture of nature, for nature … something more integral and consistent with the laws of nature' (Wright, 1993, pp302, 306). In words Morris and Ruskin would have applauded, Wright argued that a building 'should love the ground on which it stands' reflecting the topography, materials and life of the place (1993, p307).

Organic architecture is 'human scale in all proportions', but is a blending of nature with human created space so that it would be difficult to 'say where the garden ends and where the house begins … for we are by nature ground-loving animals, and insofar as we court the ground, know the ground, and sympathize with what it has to give us' (1993, p309). Wright's vision extended beyond architecture to a vision of the larger settlement patterns that he called 'Broadacre City', arguing that organic architecture had to be more than an island in a society with other values. In his interest on harmonizing site, form and function, and using natural materials and solar energy, in Wright is a precursor to the green building movement and the larger endeavour of ecological design. And in his often random musings about an 'organic society' he foreshadowed the present dialogue about the sustainability of modern society.

Ecological design, however, is not just about calibrating human activities with natural systems. It is also an inward search to find patterns and the order of nature written in our senses, flesh and human proclivities. There is no line dividing nature outside from inside; we are permeable creatures inseparable from nature and natural processes in which we live, move and have our being. We are also sensual creatures with five senses that we know and others that we only suspect. At its best, ecological design is a calibration, not just of our sense of proportion that the Greeks understood mathematically, but a finer calibration of the full range of our sensuality with the built environment, landscapes and natural systems. Our buildings are thoughts, words, theories and entire philosophies crystallized for a brief time into physical form that reveal what's on our mind and what's not. When done right, they are a form of dialogue with nature and our own deeper, sensual nature. The sights, smells, textures and sounds of the built environment evoke memories, initiate streams of thought, engage, sooth, provoke, bind or block, open or close possibilities. When done badly, the result is spiritual emptiness characteristic of a great deal of modern design that reveals, in turn, a poverty of thought, perception and feeling.

More specifically, we are creatures shaped inordinately by the faculty of sight, but seeing is anything but simple. Oliver Sacks once described a man blind since early childhood whose sight once restored found it to be a terrible and confusing burden preferring to return to blindness and his own inner world of touch. 'When we open our eyes each morning,' Sacks writes, 'it is upon a world we have spent a lifetime *learning* to see' (Sacks, 1993, p64). And we can lose not only the faculty of sight, but the ability to see as well. Even with 20–20 vision, our perception is always selective because our eyes permit us to see only within certain ranges of the light spectrum and because personality, prejudice, interest and culture further filter what we are able to see. Sacks notes that individual people can choose not to see and I suspect the same is true for cultures as well. The affinity for nature, a kind of sight, is much diminished in modern cultures.

Collective vision cannot be easily restored by more clever thinking, but, as David Abram puts it only 'through a renewed attentiveness to this perceptual dimension that underlies all our logics, through a rejuvenation of our carnal, sensorial empathy with the living land that sustains us' (1996, p69). Drawing from the writings of Merleau-Ponty, Abram describes perception as interactive and participatory in which 'perceived things are encountered by the perceiving body as animate, living powers that actively draw us into relation … both engender(ing) and support(ing) our more conscious, linguistic reciprocity with others' (1996, p90). Further, sight as well as language and thought are experienced bodily as colours, vibrations, sensations and empathy, not simply as mental abstractions. The ideas that viewer and viewed are in a form of dialogue and that we experience perception bodily runs against the dominant strains of Western philosophy. Plato, for illustration, has Socrates say that 'I'm a lover of learning, and trees and open country won't teach me anything whereas men in the town do' (Phaedrus, 479). Plato's world of ideal forms existed only in the abstract. Similarly, the Christian heaven exists purely somewhere beyond earthly and bodily realities. Both reflected the shifting balance between the animated sacred, participatory world and the linear, abstract, intellectual world. Commenting on the rise of writing and the priority of the text, Abram says that 'the voices of the forest, and of the river began to fade … language loosen(ed) its ancient association with the invisible breath, the spirit sever(ed) itself from the wind, and psyche dissociate(d) itself form the environing air' (1996, p254). As a result, 'human awareness folds in upon itself and the senses – once the crucial site of our engagement with the wild and animate earth – become mere adjuncts of an isolate and abstract mind' (1996, p267).

Through the designed object we are invited to participate in seeing something else, a larger reality. The creators of Stonehenge, I think, intended worshippers to see not just circles of artfully arranged stone, but the cosmos above and maybe within. The Parthenon is a temple dedicated to the goddess Athena, but also a visible testimony to an ideal existing in mathematical harmonies, proportion and symmetry discoverable by human reason. The builders of Gothic cathedrals intended not just monumental architecture but a glimpse of heaven and a home for sacred presence. For all of the crass, utilitarian ugliness of the factories, slums and glittering office towers, the designers and builders of the fourth revolution intended to reveal a world of abundance and human potentials in a world they otherwise deemed uncertain and violent, ruled by the economic laws of the jungle.

Finally, the practice of ecological design is rooted in the emerging science of ecology and the specific natural characteristics of specific places. The fifth revolution is not merely a more efficient recalibration of energy, materials and economy in accord with ecological realities, but a deeper and more coherent vision of the human place in nature. Ecological design is, in effect, the specific terms of a declaration of peace with nature that begins in the science of ecology and the recognition of our dependence on the web of life (Capra, 1996). In contrast to the belief that nature is little more than a machine and its parts merely resources, for designers of the fifth revolution it is, as Aldo Leopold put it:

> A fountain of energy flowing through a circuit of soils, plants, and animals. Food chains are the living channels which conduct energy upward; death and decay return it to the soil. The circuit is not closed; some energy is dissipated in decay, some is added by absorption from the air, some is stored in soils, peats, and long-lived forests; but it is a sustained circuit, like a slowly augmented revolving fund of life. There is always a net loss by downhill wash, but this is normally small and offset by the decay of rocks. (Leopold, 1949, p216).

Energy flowing through the 'biotic stream' moves 'in long or short circuits, rapidly or slowly, uniformly or in spurts, in declining or ascending volume', what ecologists call food chains. For designers, the important point is that the internal processes of the biotic community, the ecological books in effect, must balance so that energy used or dissipated by various processes of growth must be replenished. Leopold proposed three basic ideas:

1 that land is not merely soil;
2 that the native plants and animals kept the energy circuit open; others may or may not;
3 that man-made changes are of a different order than evolutionary changes, and have effects more comprehensive than is intended or foreseen. (Leopold, 1949, p218)

Ecological design, as Leopold noted, begins in the recognition that nature is not simply dead material or simply a resource for the expression of human wants and needs, but rather 'a community of soils, waters, plants, and animals, or collectively: the land' of which we are a part (Leopold, 1949, p204). But Leopold did not stop at the boundary of science and ethics, he went on to draw out the larger implications. For reasons of both necessity and right, the recognition that we are members in the community of life 'changes the role of *Homo sapiens* from conqueror of the land-community to plain member and citizen of it' (1949, p204). The 'upshot' is Leopold's classic statement that 'a thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise' (1949, pp224–225). We will be a long time understanding the full implications of that creed, but Leopold, late in his life, was beginning to ponder the larger social, political and economic requisites of a fully functioning land ethic.

Like Leopold's land ethic, ecological design represents a practical marriage of ecologically enlightened self-interest with the recognition of the intrinsic values of natural systems. Once consummated, however, the marriage branches out into a family of possibilities. Economics rooted in the realities of ecology, for example, requires the preservation of natural capital of soils, forests and biological diversity; which is to say economies that operate within the limits of the earth's carrying capacity (Daly, 1996). An ecological politics requires the recalibration of the complexities and timescales of ecosystems with the conduct of the public business. An ecological view of health would begin with the recognition that the body exists within an environment, not as a kind of isolated machine (Kaptchuk, 2000). Religion grounded in the operational realities of ecology would build on the human role as stewards and the obligation to care for the Creation (Tucker, 2003). An ecological view of agriculture would begin with the realities of natural systems, aiming to mimic the way natural systems function (Jackson, 1980). An ecological view of business/industry would aim to create solar powered industrial and commercial ecologies so that every waste product cycles as an input in some other system (McDonough and Braungart, 2002).

In whatever manifestation, the goal of ecological design is to go 'from conqueror of the land community to plain member and citizen of it' (Leopold). But there is no larger theory of ecological design, nor is there a textbook formula that works for practitioners across many different fields and at varying scales. And neither should we presume agreement on what it means for humankind to become a 'plain member and citizen of the biotic community'. In other words, we have a compass but no map. Architect Samuel Mockbee, founder of the Rural Studio, enjoined his students working with the poor in Hale County, Alabama, only to make their work 'warm, dry, and noble'. Warm and dry are easy for the most part because they are felt somatically, noble is hard because it requires us to make judgements about what we ought to do relative to some standard higher than creature comfort. But in the best sense of the word it is synonymous with decent, worthy, generous, magnificent, proud and resilient. And it ought to be synonymous with ecological design as well.

Ecology, the 'subversive science', begins with the recognition of our practical connections to the physical world, but it does not stop there. The awareness of the many ways by which we are connected to the web of life would lead intelligent and scientifically literate people to protect nature and the conditions necessary to it for reasons of self-interest. But our knowledge, always incomplete and often wrong, is mostly inadequate to the task of knowing what's in our interest, whether we wish to define that as 'highest' or 'lowest', let alone discerning exactly what parts of nature we must accordingly protect and how to do it. Science notwithstanding, often we do not know what we are doing and why. More subversive still are questions concerning the interests and rights of lives and life across the boundaries of species and time. Since they cannot speak for themselves, their only advocates will be those willing to speak on their behalf.

There are many clever arguments used to explain why we should or should not be concerned about those whose lives and circumstances would be affected by our action or inaction. Like so many tin soldiers, arrayed across the battlefield of abstract intellectual combat, they assault frontally or by flank, retreat only to regroup, and charge again, each battle giving rise to yet another. But in the end, I think, such questions will not be decided by intellectual combat and argumentation, however smart, but rather more simply and profoundly by affection – all of those human emotions that we try to capture in words like compassion, sympathy and love. Love, in other words, neither requires nor hinges on intellectual argument. It is a claim that we recognize as valid but for reasons we could never describe satisfactorily. In the end it is a nameless feeling that we accept as both a limitation on what we do and a gift we offer. Pascal's observation that the heart has reasons that reason does not know sums the matter. Love is a gift but the giver expects no return on the investment and that defies logic, reason and even arguments about selfish genes.

So, after all of the intellectualization and clever arguments, whether we choose to design with nature or not will come down to a profoundly simple matter of whether we love deeply enough, artfully enough, and carefully enough to preserve the web on which all life now and in the future depends. Ecological design is simply an informed love applied to the dialogue between humankind and natural systems. The origins of the practice of ecological design can be traced far back in time, but there are deeper origins found in the recesses of the human heart.

Towards Design Education

The basic principles of ecological design are these (van der Ryn and Cowan, 1996; McDonough and Braungart, 2002):

- use sunshine and wind;
- preserve diversity;
- account for all costs;
- eliminate waste;
- solve for pattern;
- protect human dignity;
- leave wide margins for error, malfeasance and ignorance.

The basic principles of modern education appear to be these:

- the purpose of education is to extend human mastery of nature;
- learning is intellectual, not emotional;
- curriculum is organized by disciplines and divisions;
- analytical reasoning (reductionism) and quantification are superior to other modes of knowing;
- schools are best organized like factories to maximize efficiency;
- success is measured first by tests, later by careers in the industrial world;
- academic architecture is a function of cost and efficiency.

The recalibration of education with ecology, and specifically one aimed to inform our role as designers, has large implications for the substance and process of education and the expectations that we bring to it. But what follows is perhaps best regarded as notes for a seminar on design education, a scouting expedition, toward that end rather than a set of firm conclusions or a blueprint.

First, in contrast to assumptions of human mastery of nature, the starting point for ecological design education is a more humble and serious consideration of the 3.8 billion years of evolutionary history. Nature, for ecological designers, is not something just to be mastered, but a tutor and mentor for human actions. Janine Benyus author of *Biomimicry* points out, for example, that spiders make biodegradable materials stronger than steel and tougher than Kevlar without fossil fuels, toxic chemicals and the product is biodegradable (Benyus, 1998). From nothing more than substances in seawater, molluscs make ceramic-like materials that are stronger and more durable than anything we know how to make. These and thousands of other examples are models for manufacturing, the design of technologies, farming, machines and architecture that are orders of magnitude more efficient, elegant and durable than our best industrial capabilities. But the foundational pedagogy begins with nature as tutor and mentor.

Ecological design, further, is not simply a mimicking of nature toward a smarter kind of industrialization, but rather a deeper revolution in the place of humans in nature. In Wendell Berry's words, design begins with questions 'What's here? What will nature permit us to do here? What will nature help us do here?' The capacity to question presumes the humility to ask, the good sense to ask the right questions, and the wisdom to follow the answers to their logical conclusions. Ecological design is not a monologue of humans talking to nature, but a dialogue that requires the capacity to listen, discern and learn from nature. When we get it right, the results in John Todd's words are 'elegant solutions predicated on the uniqueness of place'. The industrial standard, in contrast, is based on the idea that nature can be tortured into revealing her secrets, as Francis Bacon so revealingly put it. Brute force and human cleverness, not co-evolution and cooperation are at the heart of the modern worldview. So, too, standardization and a one size fits all strategy making industrial design look the same and operate by the same narrow logic everywhere. But this is no great victory for humankind because the mastery of nature, in truth, represents the mastery of some men over other men using nature as the medium, as C. S. Lewis once put it (1947).

Second, pedagogy informed by an ecological perspective does not begin with the assumption that humans are infinitely plastic. On the contrary, our sense of order and affinity for design are bounded by our long evolutionary history and our dawning sensations of life. The first safe haven we sense is our mother's womb. Our first awareness of regularity is the rhythm of our mother's heartbeat. Our first passage way is her birth canal. Our first sign of benevolence is at her breast. Our first awareness of self and other comes from sounds made and reciprocated. Our first feelings of ecstasy come from bodily release. The first window through which we see is the eye. The first tool we master is our own hand. The world is first revealed to us through the senses of touch and taste. Our first worldview is formed within small places of childhood. Our ancestors' first inkling that they were not alone was the empathetic encounter with animals. The first music they heard were sounds made by birds, animals, wind and water. Their first source of wonder, perhaps, was the undimmed night sky. Their first models of shelter were those created by birds and animals. The first materials humans used for building were mud, grass, stone, wood and animal skins. Their first metaphors were likely formed from daily experiences of nature. The first models for worship found in what early humans perceived as cosmic harmony were those of the dwelling.

We are creatures shaped by the interplay between our senses and the world around us. We know of five senses and have reason to believe that there are others. For example, some evidence suggests that we have a rudimentary awareness of being watched and there are other possibilities. Aboriginal peoples can walk with unerring accuracy across trackless landscapes in the dark of night. Across all cultures and times, good design is a close calibration of our sensuality with inspiration, creativity, place, form and materials. Good design feels right and is a pleasure to behold and experience for reasons that we understand at an intuitive level, but have difficulty explaining.

Third, all design involves decisions about how society provides food, energy, shelter, materials, water and waste cycling, and distributes risks, costs and benefits and is thereby unavoidably political. Design education, by the same logic, is political having to do with decisions about energy, forests, land, water, biological diversity, resources and the distribution of wealth, risks and benefits. Often cast as 'liberal' or 'conservative', such decisions in our time are, in fact, often about how the present generation orients itself to the interests of its children and grandchildren. One can arrive at a decent regard for their prospects as either a conservative or as a liberal. These are not opposing positions so much as they are different sides of a single coin. The point is that harmonizing social and economic life with ecological realities will require choices about energy technologies, agriculture, land use, settlement patterns, materials, the handling of wastes and water that are inescapably political and will distribute risks and benefits in one way or another.

Further, as the Greeks understood, design entails choices that enhance or retard civic life and the prospects for citizenship. But in our time 'We are witnessing the destruction of the very idea of the inclusive city' and with it the arts of civility, citizenship and civilization (Rogers, 1997, p10). By including or excluding possibilities to engage each other in convivial dialogue the creators of urban spaces enhance or diminish civility, urbanity and the civic prospect. It is no accident, I think, that crime, loneliness and low participation became epidemic as spaces such as town squares, street markets, front porches, corner pubs and parks were sacrificed to the automobile, parking lots and urban sprawl. Better design alone cannot cure these problems, but they can help to engage people with their places as thoughtful and engaged citizens.

Fourth, ecological design implies a better and more robust economics. In an age much devoted to the theology of the market, disciples of the conventional wisdom believe it imprudent to design ecologically if the costs are even marginally more than conventional design. Based on incomplete and highly selective accounting, that view is almost always wrong because it overlooks the fact that we – or someone – sooner or later will pay the full costs of bad design, one way or another. In other words, society pays for ecological design whether it gets the benefits of it or not. Honest accounting, accordingly, requires that we keep the boundaries of consideration as wide as possible over the long term and have the wit to deduct the collateral benefits that come from doing things right. For example, ignoring the costs of wars fought for 'cheap' oil, or those of climate change, air pollution and the health effects of urban sprawl, an SUV is cheap enough. But price and cost should not be confused. It is the height of folly to believe that we can eliminate forests, pollute, squander resources, erode soils, destroy biological diversity, remodel the biogeochemical cycles of the Earth, and create ugliness, human and ecological, without consequence. The truth is that, sooner or later, the full costs will be paid one way or another. The problem, however, is that the costs of environmental dereliction are diffuse and often can be deferred to some other persons and to some later time, but they do not thereby disappear. The upshot is that much of our apparent prosperity is phony and so too the intellectual and ideological justifications for it.

The application of short-term economics to architecture, in particular, has been little short of disastrous. 'The rich complexity of human motivation that generated architecture', in Richard Rogers' words, 'is being stripped bare. Building is pursued almost exclusively for profit' (1997, p67). By such logic we cannot afford to design well and build for the distant future. The results have been evident for a long time. In the mid-19th century, John Ruskin noted that 'Ours has the look of a lazy compliance with low conditions' (1880/1989, p21). But even Ruskin could not have foreseen the blight of suburban sprawl, strip development, urban decay, driven by our near terminal love affair with the automobile and inability to plan sensibly. The true costs, however, are passed on to others as 'externalities' thereby privatizing the gains while socializing the costs. The truth is, as it has always been, that a phony prosperity is no good economy at all. False economic reckoning has caused us to lay waste to our countryside, abandon our inner cities and the poor, and build auto-dependent communities that are contributing mightily to climatic change and rendering us dependent on politically unstable regions for oil.

An economy judged by the narrow industrial standards of efficiency will destroy values that it cannot comprehend. Measured as the output for a given level of input, maximizing efficiency creates disorder, that is to say, inefficiency at higher levels. The reasons are complex but have a great deal to do with our tendency to confuse means with ends. As a result efficiency often becomes an end in itself while the original purposes (prosperity, security, benevolence, reputation, etc.) are forgotten. The assembly line was efficient for the manufacturing firm, but its larger effects on workers, communities and ecologies were often destructive and the problems for which mass production was a solution have been compounded many times over. Neighbourliness is certainly an inefficient use of time on any given day, but not when considered as a design principle for communities assessed over months and years. For engineers, freeways are efficient at moving people up to a point, but they destroy communities, promote pollution, cause congestion, create dependence on foreign oil and eliminate better alternatives including design for access that precludes the need for transportation. WalMart, similarly, is an efficient marketing enterprise, but eliminates its competitors and many things that make for good communities, including jobs that pay decent wages. Success on such terms will eventually destroy WalMart and a great deal more. And, of course, nuclear weapons are wonderfully efficient and quick devices as well. Ecological design, in contrast, implies a different standard of efficiency oriented toward ends, not means, the whole, not parts, and the long term not the short term.

Fifth, design education must be grounded in an honest assessment of human capabilities. Ecological design, like all human affairs, has to be carried out in the full recognition of human limitations, including the discomfiting possibility that we are incurably ignorant. T. S. Eliot put it this way:

> Human kind
> Cannot bear very much reality. (T. S. Eliot, 1971, p119)

In other words, we are inescapably ignorant and the reasons are many. We are ignorant because reality is infinite relative to our intellectual and perceptual capacities. We are ignorant because we individually and collectively forget things that we once knew. We are ignorant because every human action changes the very system we aim to understand. We are ignorant because of our own limited intelligence and because we cannot know in advance the unintended effects of our actions on complex systems. We are ignorant even about the proper ends to which knowledge might be put. Not the least, we are ignorant, as Eliot noted, because, sometimes, we choose to be.

Alas many seem to prefer it that way. From the publication of the *Global 2000 Report* in 1980 to the present there is a veritable mountain of scientific evidence about human impacts on ecosystems and the biosphere and ways to minimize or eliminate them. But our collective sleepwalk toward the edge of avoidable tragedy continues suggesting that we are not so much rational creatures as we are adept and creative rationalizers.

Similarly, designers must reckon with the uncomfortable probability that the amount of credulity in human societies remains constant. This is readily apparent by looking backward through the rearview mirror of history to see the foibles, fantasies and follies of people in previous ages (Tuchman, 1984). For all our pretensions to rationality, others at some later time will see us similarly. The fact is that humans, in all ages and times, are inclined to be as unsceptical and sometimes as gullible as those living in any other – only the sources of our befuddlement change. People of previous ages read chicken entrails, relied on shaman, consulted oracles. We, far more sophisticated but similarly limited, use computer models, believe experts and exhibit a touching faith in technology to fix virtually everything. But who among us really understands how computers or computer models work, or are aware of the many limits of expertise, or the ironic ways in which technology 'bites back'? Has gullibility declined as science has grown more powerful? No, if anything it is growing because science and technology are increasingly esoteric and specialized and hence removed from daily experience. Understanding less and less of either, we will believe almost anything. Gullibility feeds on mental laziness and is enforced by social factors of ostracism, social pressures for conformity, and the pathologies of groupthink that penalize deviance.

This line of thought raises the related and equally unflattering possibility that stupidity may be randomly distributed up and down the socioeconomic-educational ladder. As anecdotal evidence for the latter, I offer the observation that I have likely known as many brilliant people without much formal learning as those certified by a PhD. And there are likely as many thorough-going, fully degreed fools as there are un-degreed fools. I am a professional 'educator' and an admission of such gravity leads me to think that the gift of intelligence and intellectual clarity can be focused and sharpened a bit, but can neither be taught nor conjured. The numerous examples of the under-degreed or academic failures include Albert Einstein, Winston Churchill, Frank Lloyd Wright and Amory Lovins. One should not conclude, however, that formal schooling is useless, but that its effectiveness, for all of the puffery that adorns college catalogues and educational magazines, is considerably less than advertised. And there are those as lawyer John Berry once noted who have been 'educated beyond their comprehension', people made more errant by the belief that their ignorance has been erased by the possession of facts, theories and the adornment of weighty learnedness.

Nor does the outlook for intelligence necessarily brighten when we consider the limitations of large organizations. These, too, are infected with our debilities. Most of us live out our professional lives in organizations or work for them as clients and often discover to our dismay that the collective intelligence of organizations and bureaucracies is often considerably less than that of any one of its individual employees. We are baffled by the discrepancy between smart people within organizations exhibiting a collective IQ less than, say, kitty litter. We understand human stupidity and dysfunction because we encounter it at a scale commensurate with our own. But confronted with large-scale organizations whether corporations, governments or colleges and universities we tend to equate scale, prestige and power with perspicacity and infallibility. Nothing could be farther from the truth. The intelligence of a large-scale organization (if that is not altogether oxymoronic) is limited by the obligation to earn a profit, enlarge its domain, preserve entitlements or maintain a suitable stockpile of prestige.

Our human frailties infect the design professions as well. Buildings and bridges sometimes fall down (Levy and Salvadori, 1992). Clever designs can induce an astonishing level of illness and destruction. Beyond some scale and limits design becomes guesswork. British engineer, A. R. Dykes puts it this way: 'Engineering is the art of modeling materials we do not wholly understand, into shapes we cannot precisely analyze so as to withstand forces we cannot properly assess, in such a way that the public has no reason to suspect the extent of our ignorance' (www.ukcivilengineering.co.uk/quotes.html). In various ways the same is true in other design professions and virtually every other field of human endeavour.

The point is simply to say that human limitations will be evident in every design, project and system however otherwise clever. From this there are, I think, two conclusions to be drawn. The first is simply that design, whether of bridges, buildings, communities, factories, or farms and food systems, ought to maximize the capacity of a system to withstand disturbance without impairment, which is to say resilience. Ecological design does not assume the improbable: human infallibility, technological perfection or some *deus ex machina* that magically rescues us from folly. Rather ecological designers aim to work at a manageable scale, achieving flexibility, redundancy and multiple checks and balances while avoiding the thresholds of the irreversible and irrevocable (Lovins and Lovins, 1982, ch 13; Lovins, 2002).

Forewarned about human limitations, we might further conclude that a principal goal of designers ought to be the improvement of our collective intelligence by promoting mindfulness, transparency and ecological competence. Compared to people of any other time, the public is less aware of how it is provisioned with food, energy, water, materials, security and shelter, and how its wastes are handled. Industrial design cloaked the ecological fine print of what are often little better than Faustian bargains providing luxury and convenience now, while postponing ruin to some later time. Ecological design, on the contrary, ought to demystify the world, making us mindful of energy, food, materials, water and waste flows, which is to say the ecological fine print by which we live, move and have our being.

Design is always a powerful form of education. Only the terminally pedantic believe that learning happens just in schools and classrooms. The built environment in which we spend over 90 per cent of our lives is at least as powerful in shaping our ideas and views of the world as anything learned in a classroom. Suburbs, shopping malls, freeways, parking lots and derelict urban spaces have considerable impacts on how we think, what we think about and what we can think about. The practice of design as a form of public instruction is a jailbreak of sorts, liberating the ecological imagination from the tyranny of imposed forms and relationships characteristic of the fossil fuel powered industrial age. Architecture, landscape architecture and planning carried out as a form of public education aims to instruct about energy, materials, history, rhythms of time and seasons, and the ecology of the places in which we live. It would help us become mindful of ecological relationships and engage our places creatively.

Six, awareness of human limitations might cause us, perhaps, to look more favourably on past societies and vernacular design skills created by people at the periphery of power, money and influence. The truth is that practical adaptation to the ecologies of particular places over long periods of time has often resulted in spectacularly successful models of ecological design (Rudofsky, 1964). It may well be that the ecological design revolution will be driven, at least in part, by experience accumulated from the periphery not from the centre, and led by people skilled at solving the practical problems of living artfully by their wits and good sense in particular places. The success of vernacular design across all cultures and times underscores the possibility that design intelligence may be more accurately measured at the level of the community or culture, rather than at the individual level.

Seven, in modern pedagogy, a great deal of art and philosophy has been cut off from the world of nature. The aesthetic standard for ecological design, on the contrary, reconnects to the natural world so artfully as to cause no ugliness, human or ecological, somewhere else or at some later time. The standard, in other words, requires a more robust sense of aesthetics that rises above the belief that beauty is wholly synonymous with form alone. Every great designer from Vitruvius through Frank Lloyd Wright demonstrated that beauty in the large sense had to do with the effects of buildings on the human spirit and our sense of humanity, and their impacts on specific places. But the standards for beauty must be measured on a global scale and longer time horizon so that beauty includes the upstream physical effects at wells, mines and forests where materials originate as well as the downstream effects on climate, human health and ecological resilience. The things judged truly beautiful will in time be regarded as those that raised the human spirit without compromising human dignity or ecological functions elsewhere. Architecture and landscape architecture, in other words, are a means to higher ends.

Eight, the education of professional designers requires substantial changes. As much art as science, the design professions are not simply technical disciplines, having to do with the intersection of form, materials, technology and real estate. The design professions such as architecture, landscape architecture and urban planning are first and foremost practical liberal arts with technical aspects. Writing in the first century BC, Vitruvius proposed that architects:

> be educated, skilful with the pencil, instructed in geometry, know much history, have followed the philosophers with attention, understand music, have some knowledge of medicine, know the opinions of the jurists, and be acquainted with astronomy and the theory of the heavens (1960, pp5–6).

That is a start of a liberal and liberating education. Design education, therefore, ought to be a part of a broad conversation that includes all of the liberal arts. In George Steiner's words:

> Architecture takes us to the border. It has perennially busied the philosophic imagination, from Plato to Valery and Heidegger. More insistently than any other realization of form, architecture modifies the human environment, edifying alternative and counter-worlds in relationships at once concordant with and opposed to nature (Steiner, 2001, pp251–252)

In countless ways all design, even the best, damages the natural world. Extraction and processing of materials depletes landscapes and pollutes. Building construction, operation and demolition creates large amounts of debris. Agriculture inevitably simplifies ecosystems. A new breed of ecological designers, accordingly, must be even more intellectually agile and broader, capable of orchestrating a wide array of talents and fields of knowledge necessary to design outcomes that can be sustained within the ecological carrying capacity of particular places.

Nine, education is aimed in some fashion to heal us by the systematic cultivation of reason, thoughtfulness and memory from the more egregious problems inherent in the human condition. As a further step in this progression, the design professions ought to be regarded as healing arts, an ideal rooted in Vitruvius' advice that architects ought to pay close attention to sunlight, the purity of water, air movements and the effects of the building site on human health. The word 'healing' has a close affinity with other words such as holy and wholeness. A larger sense of the profession that architect Thomas Fisher (2001) deems a 'calling', would aim for the kind of wholeness that creates not just buildings but integral homes and communities.

Compare, for example, the idea that 'architecture applies only to buildings designed with a view to aesthetic appeal' (Pevsner, 1990, p15) with architecture defined as 'the art of place-making' and creation of 'healing places' (Day, 2002, pp10, 5). In the former, design changes with trends in fashionable forms and materials. It is often indifferent to place, people and time. The goal is to make monumental, novel and photogenic buildings and landscapes that express mostly the ego and power of the designer and owner. In contrast, the making of healing places signals a larger allegiance to place that means, in turn, a commitment to the health of other places. Place-making is an art and science disciplined by locality, culture and ecology requiring detailed knowledge of local materials, weather, topography and the nature of particular places and a creative dialogue between past, present and future possibilities. It is slow work in the same sense that caring and careful have a different clock speed than carelessness. Place-making uses local resources thereby buffering local communities from the ups and downs of the global economy, unemployment and resource shortages (Sutton, 2001, p200).

Practised as a healing art, architects, for example, would design buildings and communities that do not compromise the health of people and places, drawing on the accumulated wisdom of placed cultures and vernacular skills. They would aim to design buildings that heal what ails us at deeper levels. At larger scales the challenge is to extend healing to urban ecologies. Half of humankind now lives in urban areas, a number that will rise in coming decades to perhaps 80 per cent. Cities built in the industrial model and to accommodate the automobile are widely recognized as human, ecological and, increasingly, economic disasters. Given a choice, people leave such places in droves. But we have good examples of cities as diverse as Copenhagen, Chattanooga and Curitiba that have taken charge of their futures to create livable, vital and prosperous urban places – what Peter Hall and Colin Ward (1998) have called 'sociable cities'. In order to do that, however, designers must see their work as fitting in a larger human and ecological tapestry.

As a healing art, ecological design aims toward harmony which is the proper relation of parts to the whole. As health professionals is there a design equivalent to the Hippocratic Oath in medicine that has informed medical ethics for two millennia? Are there things that designers should not design? What would it mean for designers to 'do no harm'?

Looking ahead, the challenge to the design professions is to join ecology and design in order to create buildings, communities, cities, landscapes, farms, industries and entire economies that accrue natural capital and are powered by current sunlight – perhaps, one day, having no net ecological footprint. The standard is that of the healthy, regenerative ecosystem. In the years ahead we will discover a great deal that is new and rediscover the value of vernacular traditions such as front porches, village squares, urban parks, corner pubs, bicycles, pedestrian-scaled communities, small and winding streets, local stores, riparian corridors, urban farms and wild areas, and well-used landscapes.

Design practised as a healing art is not a panacea for the egregious sins of the industrial age. However well-designed, a world of 7 to 10 billion human beings with unlimited material aspirations will sooner than later overwhelm the carrying capacity of natural systems as well as our own management abilities. There is already considerable evidence that humans now exceed the carrying capacity of Earth. Further, ecological design is not synonymous with building; often the best design choices will require adaptive reuse or more intense and creative uses of existing infrastructure. Sometimes it will mean doing nothing at all, a choice that requires a clearer and wiser distinction between our needs and wants.

What ecological designers can do, and all they can do, is to help reduce our ecological impacts and buy us time to reckon with the deeper sources of our problems that have to do with age-old questions about how we relate to each other across the boundaries and sometimes chasms of gender, ethnicity, nationality, culture and time and how we fit into the larger community of life. Ecological design, as a healing art, is only a necessary, but insufficient part of a larger strategy of healing, health and wholeness which brings us to spirit.

Finally, design education is not purely secular. For designers it is no small thing that humans are inescapably spiritual beings, but only intermittently religious. Philosopher Erazim Kohak once noted, that 'Humans can bear an incredible degree of meaningful deprivation but only very little meaningless affluence' (Kohak, 1984, p170). In the former condition most of us tend to grow, harden and mature while being undone in the latter. This is not a case for deliberately incurring misery which tends to multiply on its own with little assistance, but rather to underscore our inevitable spiritual nature that is like water bubbling upward from an artesian spring. Our only choice is not whether we are spiritual or not but whether that energy is directed to authentic purposes or not.

Much of the modern world, however, has been assembled as if people were machines, lacking any deeper needs for order, pattern and roots. Modern designers filled the world with buildings, artifacts and systems divorced from their context and living nature, and telling no story of their origins or place in the larger order of things. They seem to exist as if parachuted down from some alien realm disconnected from ecology, history, culture and place. Ecological design, on the other hand, is a process by which we become more and more rooted in a particular place and citizens in the community of life in that place. It is a form of storytelling by which buildings and landscapes and the uses we make of them artfully reveal the larger story of which they are a part. Modern design seldom tells any story worth hearing and hence fails to connect us to the nature, history and evolution of the places in which we live and work. Designers as storytellers aim to speak to the human spirit and helps ground our lives and labours in the celebration and awareness of specific places and in the larger story of the human journey (Berry, 1988).

Multi-Function Agricultural Biodiversity: Pest Management and Other Benefits

Geoff M. Gurr, Stephen D. Wratten and John Michael Luna

Introduction

What good are all those species that man cannot eat or sell?

(Odum, 1971)

In structurally complex landscapes, parasitism was higher and crop damage was lower than in simple landscapes …

(Thies and Tscharntke, 1999)

The first quotation above emphasizes the potential value of species for indirect commercial production benefits (soil fertility maintenance, pollination, pest and disease suppression, etc). The second, which concerns the effect of non-crop vegetation on rape pollen beetle (*Meligethes aeneus* Fabricius) in oilseed rape (*Brassica napus* L.), neatly summarizes the type of outcome now often sought from agricultural biodiversity. In California, for example, no fewer than seven proprietary seed mixtures – with names like 'Good Bug Blend' and 'Insectary Blend' – are available to growers to increase vegetational biodiversity (Bugg and Waddington, 1994). A proprietary mixture of 'weed' species is also available in Switzerland (Nentwig et al, 1998). The consequence sought is pest suppression, ostensibly via an enhancement of the populations (or at least efficacy) of predators and parasitoids. Importantly, however, increasing biodiversity per se is no guarantee of pest suppression (van Emden and Williams, 1974; Andow, 1991; Gurr et al, 1998; Landis et al, 2000). An understanding of the mechanisms by which biodiversity may favour pest management is, therefore, important.

Vegetational diversification may be beneficial via a direct, bottom-up influence of the first trophic level on the pest. Resource concentration hypothesis effects

Reprinted from *Basic and Applied Ecology* vol 4, Gurr G M, Wratten S D and Luna J M, Multi-function agricultural biodiversity: Pest management and other benefits, 107–116, Copyright (2003), with permission from Elsevier.

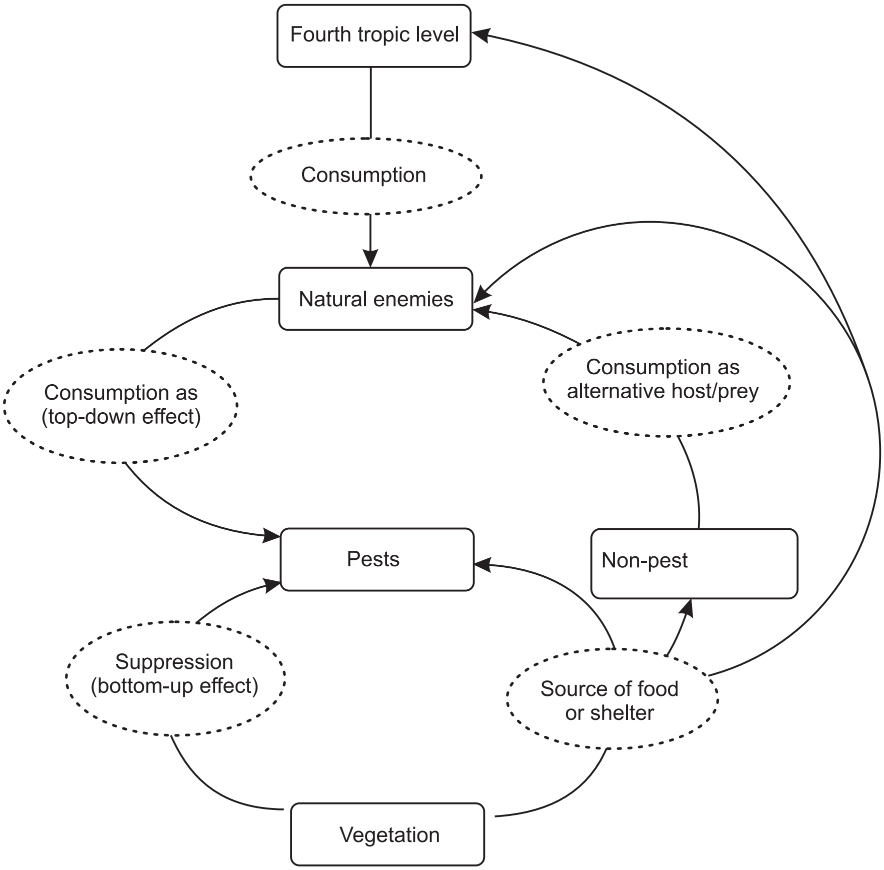

Figure 17.1 *The potential effects of vegetation on higher trophic levels and consequences for pest management*

(Root, 1973) and other mechanisms are responsible for this. Finch and Collier (2000) provide a concise review of six 'bottom-up' hypotheses, and propose a new one, the 'appropriate/inappropriate landings' hypothesis. Trap cropping (Smith and McSorley, 2000) is another potential mechanism. Pest suppression may result also from 'top-down' effects via enhancement of natural enemies (the third tropic level: Eber, 2001); conservation biological control; or Root's (1973) 'enemies hypothesis'.

In a detailed, quantitative review, Andow (1991) found that although natural enemy densities tended to be greater in polycultures than in monocultures, only slightly more than half of the 287 herbivore species were consistently less abundant in polycultures. One reason for this inconsistent effect of enhanced vegetational biodiversity is that the effects of different types of plants on natural enemies can vary markedly (Nentwig, 1992; Colley and Luna, 2000). There may also be effects on other trophic levels (Figure 17.1). For example, plants can provide resources that favour the pest (e.g. Baggen and Gurr, 1998) or members of the fourth trophic level that could then attack natural enemies of pests (e.g. Stephens et al, 1998). Despite such potential problems, there are many successful instances of biodiversity being used in agroecosystems to favour natural enemies, suppress pests and, in some cases at least, reduce crop damage (Barbosa, 1998; Gurr et al, 2000; Landis et al, 2000).

The focus of this review is the use of biodiversity to enhance pest management. We first present a concise overview of the ways in which this may be achieved. We then build on this to argue that there is a hierarchy of broader benefits to agriculture and society of enhancing biodiversity on farms. Full recognition of such multi-function agricultural biodiversity can serve only to encourage appropriate societal incentive schemes and consequent adoption by farmers.

Enhancing Biodiversity for Biological Control

The degree of complexity involved in increasing biodiversity to enhance pest management ranges from merely diversifying plant age structure within a monoculture to the opposite extreme of landscape level diversification including non-crop and perennial vegetation (Table 17.1).

Often, attempts to diversify agroecosystems remove or reduce the negative aspects of the features that typify modern, industrialized farming. These features include the removal or degradation of non-crop habitats such as hedgerows, woodland and riparian vegetation; use of monocultures; almost total weed removal from within and around crops; large field sizes; and tillage operations of varying degrees of intensity (see Jepson, 1989 and Dent, 1995 for more details).

Diversification within a monoculture

Monocultures dominate modern, industrialized agriculture. Farmers tend to be risk-averse (Norton, 1976, 1993). This has led to some attempts to enhance pest management by making only subtle changes to normal management. In a recent example, strip-cutting of lucerne (*Medicago sativa* L.) was tested as an alternative to the normal practice of harvesting entire fields at a time (Hossain et al, 2001). In this system, natural enemies migrated from harvested strips into adjacent, unharvested ones. When these refuges were cut some weeks later, natural enemies moved into the regrowing strips. Alternating harvests over the course of the haymaking season (spring–autumn) preserved within-field habitats favourable to natural enemies and contributed to the suppression of pests (*Helicoverpa* spp.: Lepidoptera).

‘Relaxing’ the monoculture

A slightly more complex form of diversification involves growing two or more varieties or closely related species of crop. This approach is well-known to plant

Table 17.1 *Examples, with increasing levels of complexity, of biodiversity enhancement benefiting pest management*

Level of complexity	*Nature of diversification*	*Example*
Diversification within a monoculture	Make crop itself structurally more diverse	Alternating harvests of lucerne strips to give structural diversity and preserve habitat for natural enemies of *Helicoverpa* spp. (Hossain et al, 2001)
'Relax' the monoculture	Grow a mix of varieties or closely related species	Willow beetle numbers and damage reduced in mixed plantings of willow (Peacock and Herrick, 2000)
Allow non-crop vegetation within the monoculture	Allow weed growth within areas of the crop	Weed strips increase natural enemy density (Lys et al, 1994)
Diversify vegetation bordering the monoculture	Sow non-crop vegetation in field margin	Phacelia strips beside wheat as pollen source for hoverfly, natural enemies of aphids (Hickman and Wratten, 1996)
Abandon monoculture	Grow two or more crops within the field	Lucerne strip within cotton act as decoy for mirids and habitat for natural enemies of cotton pests (Mensah and Kahn, 1997)
Diversify vegetation beyond the field margin	Sown or naturally generated vegetation in fallow fields adjacent to crops	'Complex, structurally rich … large old fallows' adjacent to rape increased parasitism of rape pollen beetle and reduced crop damage (Thies and Tscharntke, 1999)
Farm-wide diversification	Agroforestry integrated with cropping and livestock	Increasing arthropod densities by use of a 'silvoarable agroforestry system' (Peng et al, 1993)
Landscape level changes	Landscapes with areas of woodland	Parasitism rates of armyworm lower in crops within complex landscapes (Marino and Landis, 1996)

pathologists as a way of slowing the spread of diseases (e.g. in rice, Wolfe, 2000), but its potential impact on insect pests is illustrated by a recent study of the willow beetle (*Phratora vulgatissima* (L.)). Beetle density, oviposition and damage were lower in mixtures of up to five willow (*Salix* spp.) varieties and species than in monocultures (Peacock and Herrick, 2000). This example illustrates that enhancement of natural enemy density is not a prerequisite for effective pest management. Its findings are consistent with the resource concentration hypothesis.

Within-field non-crop vegetation

A second characteristic of industrialized agriculture is active weed control, generally through the use of herbicides. Removal of weeds can be antagonistic to arthropod pest management. Often these non-crop plants contribute towards the resource concentration hypothesis effect. They may also favour natural enemies by providing non-host foods such as pollen and nectar, support non-pest alternative hosts or prey, and provide shelter or a moderated microclimate. Reintroducing some weeds in ways that are agronomically acceptable to farmers can restore some of the 'ecosystem services' they provide to natural enemies (Nentwig et al, 1998). In the latter study, 1.5m-wide strips of weeds used at 24m intervals within cropped areas favoured natural enemies such as syrphids, chrysopids and coccinellids. An alternative approach is to withhold all or some herbicide application in part of the crop and allow growth of the existing weed community. The headland (the area of the field in which farm machinery turns and crop productivity is often lower because of the resulting soil compaction) has been used in this manner. In British work, such 'conservation headlands' provided pollen sources for adult syrphids, *Episyrphus balteatus* (Degeer) (Cowgill et al, 1993). This resulted in a significant positive relationship between number of syrphid eggs per aphid and the density of weeds.

Genetically modified herbicide resistant crops could increase within-crop botanical diversity and invertebrate biodiversity if farmers used the technology to apply herbicides after *crop* emergence and only if weed density justified spraying. This approach contrasts with the currently common practice of prophylactic application of pre-emergent herbicides, which is necessary because many weed species are impossible to kill selectively after crop emergence. There will, however, be a temptation to use herbicide resistant crops as an opportunity to exercise more stringent levels of weed control than in conventional crops. This would have a negative impact on biodiversity.

Diversification can apply also to perennial crop systems such as orchards and vineyards, where vegetational structure can include a distinct understorey. A considerable amount of work has taken place examining the effects of this relatively common form of diversification and it is particularly widely practised in China. The ground cover plant *Ageratum conyzoides* L. (Asteraceae) has been planted or conserved in 135,000ha of citrus where it is claimed to stabilize populations of *Amblyseius* spp., predators of the citrus red mite, *Panonychus citri* McGregor (Liang and Huang, 1994).

Plants other than 'weeds' may also be introduced as strips within the area of crops. 'Beetle banks', low ridges sown to perennial, tussock forming grasses have been used in British and mainland European arable crops for over a decade to provide overwintering habitat for natural enemies of aphid pests (Thomas et al, 1991; Thomas and Goulson, 2000). Migration of predatory beetles and spiders from these habitats into the crop in the spring supplements those from the field margin. Further, because beetle banks run through the centre of fields, predators migrating from them have immediate access to regions of the crop remote from the field boundary. Many important species are non-aerial so would otherwise be slow to colonize the entire area of the large fields that are now so common. Beetle banks generate high densities of polyphagous predators. Modelling and exclusion work has shown that such natural enemies can reduce aphid densities in cereals (Chiverton, 1986; Winder et al, 1988; Winder, 1990).

Field margin non-crop vegetation

An extension of this use of non-crop vegetation is its placement adjacent to the crop within the field margin. Most commonly, nectar- or pollen-rich plants are used with the former benefiting parasitoids (e.g. Baggen and Gurr, 1998) and the latter benefiting hoverflies (e.g. Hickman and Wratten, 1996). Importantly, however, tall boundary vegetation, such as trees, may impede hoverfly dispersal into nearby areas of crop (Wratten et al, in press). Thus, habitat structure may constrain the spatial extent of the benefits from adding floral resources to existing boundaries.

Abandoning monoculture

Greater levels of complexity in diversification may be seen when monoculture is abandoned and intercropping and similar practices, in which one or more additional crop species are grown within the field, are used. This may take a variety of forms ranging in complexity from the simple inclusion of a discrete area of a secondary crop to complex spatial or temporal patterns of polycultures.

An example of a simple departure from monoculture is the use of a lucerne strip within Australian cotton crops. The effects of this were two-fold. First, the lucerne is ‘preferred’ over cotton by the green crop mirid (*Creontiades dilutus* Stal) so it acts as a decoy or trap crop. Second, lucerne provides a habitat suitable for a diverse suite of natural enemies and movement of these into the cotton crop during a pest outbreak can be achieved by mowing the lucerne or applying an attractive food spray to the cotton (Mensah and Kahn, 1997).

Dramatic trap-crop results have been obtained by drilling white or black mustard (*Sinapis alba* (L.) and *Pisum sativum* (L.)) in the outer few metres of sweet corn (*Zea mays* L.) fields in New Zealand (Rea et al, in press). The green vegetable bug (*Nezara viridula* L.) normally invades the crop from surrounding vegetation. In this work, the bugs remained in the mustard, feeding on its developing pods, and this allowed the sweet corn to reach harvest stage with virtually no damage.

Another approach to conserve and enhance diversity of agroecosystems involves the use of conservation tillage. Cover crops or existing vegetation can be suppressed with herbicides and crops direct-seeded into the residue. This form of relay intercropping has increased diversity of generalist predators (Clark et al, 1993). The use of legume cover crops as living mulches in strip tillage or relay interplanted systems is another approach that increases biodiversity in agricultural ecosystems. Dempster and Coaker (1974) found that the maintenance of clover cover between rows of brassica crops reduced populations of three insect pests (*Brevicoryne brassicae* L., *Artogeia rapae* (L.) and *Erioischia brassicae* Bouché). In an experiment involving several living mulches interseeded into cabbage, Andow et al (1986) showed that living mulches reduced populations of the flea beetle (*Phyllotreta cruciferae* Goeze) and *B. brassicae* compared with monoculture plantings of cabbage. In Hawaii, Hooks and Johnson (2001) interplanted broccoli (*Brassica oleracea* L.) with chilli pepper (*Capsicum annuum* L.) or yellow sweetclover (*Melilotus officinalis* L.). The latter treatment led to fewer Lepidoptera larvae in the broccoli heads compared with the sweet pepper or control treatments and the broccoli heads did not differ in size. Undersowing with legumes such as clover to improve soil fertility, is a traditional practice. Its potential for maintaining invertebrate and bird biodiversity has only more recently been realized (Firbank et al, 1996).

Diversification beyond the field scale

At a greater level of complexity, changes may be made that apply beyond the field boundary. The work on the effects of adjacent vegetation on rape pollen beetle from which the opening quotation was taken provides an example (Thies and Tscharntke, 1999). Oilseed rape crops with simple and structurally poor adjacent vegetation were more severely damaged by this pest and it suffered lower rates of parasitism than those observed in crops adjacent to 'complex, structurally rich … large old fallows'.

At a still larger spatial scale, potentially extending beyond the farm boundary, features such as areas of woodland and hedgerow can have a long-range effect on rates of parasitism of crop pests. In a study that compared 139 fields in a 3.2km^2 area of 'complex' landscape with 61 fields in a similar area of 'simple' landscape, the lepidopteran armyworm, *Pseudaletia unipunctata* Haworth, was parasitized at a statistically higher rate in the crops located in the former (Marino and Landis, 1996).

Benefits of Biodiversity – a Hierarchy of Scales

As is clear from the foregoing examples, enhanced agricultural biodiversity can favour pest management *via* enhanced biological control or direct (resource concentration hypothesis) effects on pests. However, benefits beyond this 'pathosystem' scale are also possible and these may be viewed in a hierarchical fashion (Figure 17.2).

Clearly, the effects of biodiversity on pests and their natural enemies have the potential to benefit the crop. However, crop production may also benefit in other ways. These effects may extend both spatially to adjacent crops and temporally to subsequent crops, so increasing the sustainability of the farming system. Benefits may also influence other, non-crop habitats both on-farm and more extensively, so lessening the environmental impact of farming and bringing other benefits to

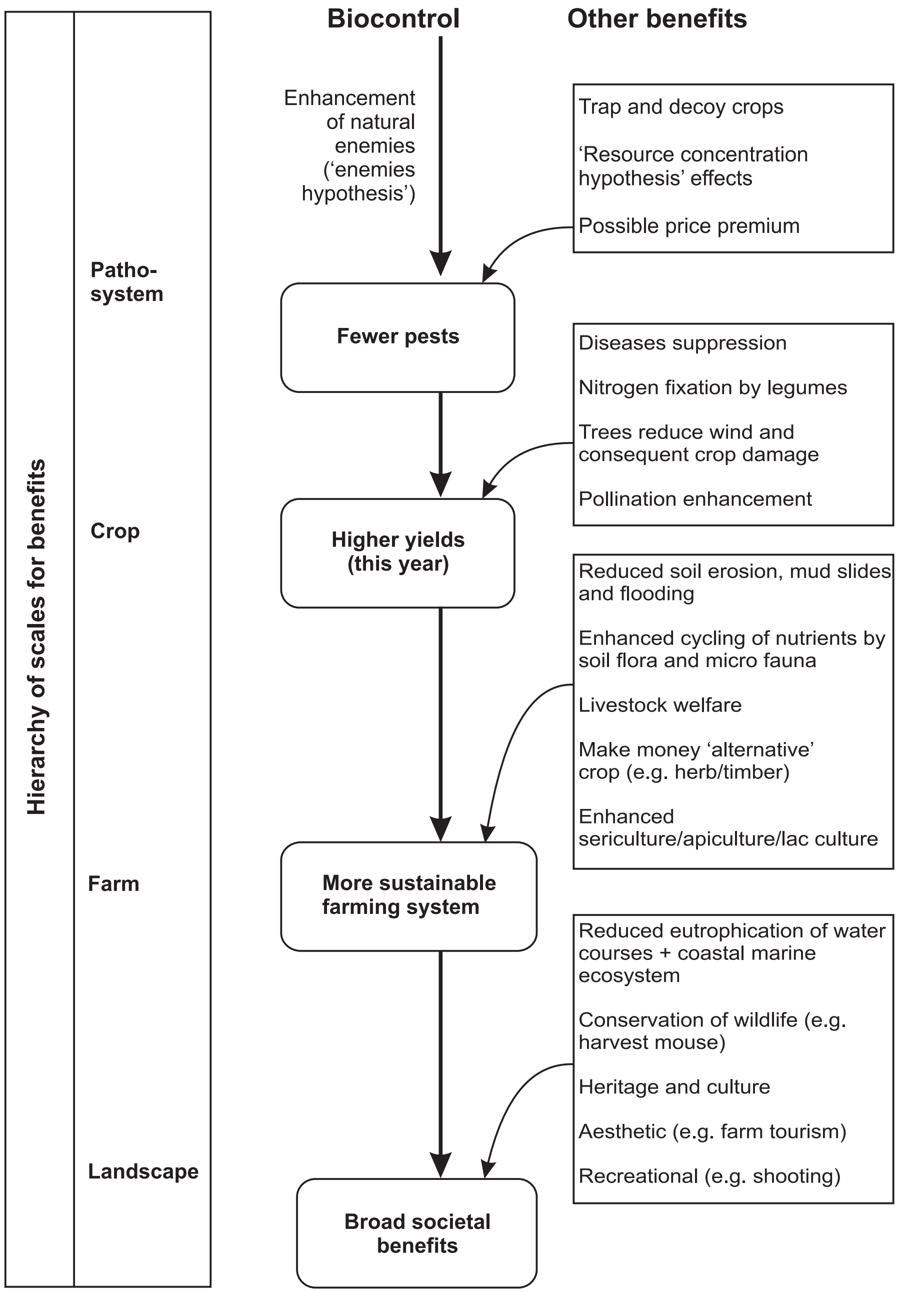

Figure 17.2 *The hierarchy of scale for potential benefits of multi-function agricultural biodiversity*

society. A detailed analysis of benefits at all these levels is beyond the scope of this paper. The argument that will be developed here is that when biodiversity is increased in an attempt to benefit pest management, there may also be a cascade of outcomes at these other hierarchical levels. The following examples develop this concept of multiple-function agricultural biodiversity.

Crop scale benefits

In instances where agricultural biodiversity has reduced pest densities, the need for pesticide inputs may be lessened although linking increased biodiversity to higher yields through pest suppression is very difficult to demonstrate (Gurr et al, 2000). This can have a spectrum of benefits, of which the most immediate is financial. Probably the most detailed financial analysis of the benefits and costs associated with introducing diversity for pest suppression is that by Thomas et al (1991). The cost of establishing a 'beetle bank' in a 20ha wheat field, combined with the value of yield lost through land taken out of production, was calculated to be US$130. However, the value of keeping aphid pest densities below the action threshold was estimated to be US$450, and the value of avoiding a 5 per cent aphid-induced yield loss was US$1000. Such figures illustrate the potential for significant economic benefits from increasing biodiversity. Potential additional advantages apply when pesticide inputs are reduced (in an Integrated Pest Management (IPM) scheme, for example) or almost completely removed (as in organic agriculture). Premium prices may be attracted for produce grown under such systems (Govindasamy and Italia, 1997) or market share can be increased because of the benefits perceived by the consumer.

Even in cases where there is no change in pesticide use, there is scope for economic benefits to the grower if crop quality and/or yield is improved. Theunissen et al (1995), for example, investigated the effects of intercropping cabbage (*Brassica campestris* L.) with white or subterranean clover (*Trifolium repens* L. and *T. subterraneum* L., respectively). In this work, the densities of various natural enemies were increased in interplanted treatments compared with the monoculture control. Densities of pests such as the cabbage moth (*Mamestra brassicae* L.) were lower in intercrop treatments and, although the total yields of the cabbage were lower in these crops as a result of plant competition, the quality of cabbages was greater as a result of lower pest damage. The effects of the diversification were, therefore, calculated to be economically favourable.

Aside from the direct effects on arthropods described above, diversification may benefit crop production in a variety of ways. The impact of bird pests and plant diseases can be reduced by aspects of vegetational diversity (Jones (1974) and Bridge (1996) respectively). Weed densities also may be reduced, as in a recent study of the effects of increased biodiversity in rice. When weeds were retained on the bunds surrounding paddies, this vegetation supported not only natural enemies of pests but also seed-collecting ants that had the effect of reducing numbers of weed seeds within paddies (Upawansa, 1999). More broadly, the vegetated bunds were more resistant to damage from floods and wild animals and were claimed to save labour and money.

In cases where biodiversity has been increased by the introduction of a leguminous plant (e.g. Theunissen et al, 1995) atmospheric nitrogen will be fixed. This important plant nutrient will be available to the diversified crop or the next crop in the rotation (Altieri, 1994). As well as directly benefiting plant growth, this effect may also be involved in the effects on host plant quality that were concluded to be important in accounting for reduced densities of *Thrips tabaci* Lindeman on leeks interplanted with clover (Belder et al, 2000). The structure and management of agricultural vegetation may also have effects on soil flora and benefit soil productivity (Hawksworth, 1991). Agroforestry, for example, supports a greater abundance of mycorrhizal fungi than does monoculture (Boddington and Dodd, 2000), and biological control of plant pathogens and nematodes can be enhanced by 'suppressive soils' – those with high microbiological activity (Whipps and Davies, 2000).

Another benefit of vegetational biodiversity is the conservation of pollinating insects that are important in many dicotyledonous crop species (Mineau and McLachlin, 1996). The occupancy rate of bumblebee domiciles was greatest in more diverse habitats (Barron et al, 2000). Overall, biodiversity can have a variety of benefits at this level of a specific diversified crop.

Farm scale benefits

The next level at which biodiversity may be beneficial is beyond the specific crop being manipulated. It considers other components of the farming system such as the intrinsic value of the introduced vegetation, impacts on adjacent but un-manipulated crops and effects on livestock within the farming system.

In instances where biodiversity is increased by adoption of some form of intercropping, the additional crops will have an added value, through their harvest being economically worthwhile. Examples include hay made from lucerne strips grown within cotton (Mensah and Kahn, 1997) or timber from agroforestry (Chitra and Solanki, 2000). There may also be complementary production benefits, such as supporting apiculture, sericulture or lac culture (Chitra and Solanki, 2000). At least some of these may apply even when the non-crop vegetation is not for harvest, for example in the case of hedges or woodland. It is also recognized that integrating trees into pastoral systems may have benefits for welfare of livestock animals via shelter from wind and provision of shade (Sinclair, 1999), as well as providing aesthetic (e.g. landscape), recreational, conservation and other advantages.

Landscape scale benefits

At this level, biodiversity may have a variety of benefits. Beetle banks and conservation headlands, both examples of vegetational diversity where increases in natural enemy density have been recorded (Thomas et al, 1991; Hassall et al, 1992; Cowgill et al, 1993) provide considerable conservation benefits. A variety of birds and small mammals use this habitat, as well as grassy field margins, and the invertebrate and plant foods it supports (Bence et al, 1999). Some animals, such as the hare (*Lepus europaeus* Pallas) and the grey partridge (*Perdix perdix* L.), are valued as game species, so provide a recreational benefit as well as additional revenue for the landholder (Boatman, 1999). Other species are of conservation significance and include the skylark (*Alauda arvensis* L.) and harvest mouse (*Micromys minutus* (Pallas)). Harvest mouse nest densities on 'beetle banks' were 47/km compared with only 5/km in field margins (Bence et al, 1999). Although some such species may be rarely encountered by members of the general public, there is considerable societal benefit in the knowledge that they do still exist ('existence value'). More tangible aesthetic benefits of biodiversity are evident in the preservation of an attractive farming landscape in which tourism and recreation can take place. Further, in countries such as Australia, New Zealand and the US, the heritage and culture of the aboriginal peoples has been threatened by land use practices introduced by European settlers. Under these circumstances, the introduction of biodiversity provides an opportunity to preserve plants of cultural significance. These may include plants of food, fibre, ceremonial and medicinal value (Patterson, 1992; Anon, 1994).

A contrasting, environmental benefit of enhanced vegetational biodiversity is the prevention of soil erosion by wind and water. The vegetationally diverse 'corridors' that Rodenhouse et al (1992) found to enhance natural enemies of soybean pests were considered to have the additional benefit of constituting a barrier to soil movement. Any such effect would, in turn, help reduce eutrophication of waterways by minimizing inputs of nutrients such as nitrogen and phosphorus and preserve sources of water for human use (Edwards and Abivardi, 1998).

At the ultimate spatial scale, biodiversity in agriculture can aid carbon sequestration (Nair, 1998). Annual carbon dioxide uptake of individual trees can be in the order of 150kg, a benefit valued at US$5 tree/year (McPherson et al, 1999).

Conclusion

The examples outlined above illustrate that when biodiversity is increased, several benefits may result at more than one hierarchical level, and thus multiple-function agricultural biodiversity is achieved. Importantly, however, because of the reductionist tendency in scientific research, many of the benefits will not have been quantified or even recognized.

Exploration of multi-function agricultural biodiversity is an important future research theme in sustainable agriculture because many farmers will be persuaded to conserve existing biodiversity and introduce additional biodiversity only if convinced to do so by a tangible package of economically rational as well as aesthetic benefits. Establishing the types and extents of these various benefits will demand a greater degree of collaboration between researchers from disciplines including pest management, soil science, wildlife ecology, economics, anthropology and social science. It is to be hoped that this special issue will spur such work.

Generating Community Change

Cornelia Butler Flora and Jan L. Flora

When Sue James and her husband Bart moved with their two teenage children to New Richland, Minnesota, from St. Louis, Missouri, they eagerly anticipated the prospect of the clean air and neighbourliness found in rural America. Big-city living had lost its lustre, and they were excited to live in the 'country'. However, a few months after their move, they realized they missed certain elements of living in a larger setting, particularly in terms of recreation. Furthermore, there were few summer jobs for teenagers in a small, rural area.

Bart and Sue often went to a small, locally owned diner for breakfast and coffee on Saturday mornings, and they met many farmers and businesspeople who lived in the town. Bart, being the new school superintendent, was a familiar face already. Bart mentioned his family's love of golf, and several other community members agreed that they wished there was a course in town. Word spread, and soon Bart and Sue decided to open the idea up for town consideration.

First, they placed a notice in the local paper announcing an open meeting to discuss construction of a community golf course; 40 people attended. Committees were set up to consider possible sites and organizational structures. At the next meeting, more than 100 people were present. Interest in the project proliferated, and it helped that all of the meetings were well covered in the local paper.

The site committee presented four potential sites, which in the following weeks were visited by most of the members of the town, even those who did not play golf. At the next community meeting, with several hundred people in attendance, the pros and cons of each site were presented. With all of this information in mind, the assembly voted on the site they wanted. The site that was chosen would be purchased from its owner, a farmer who agreed to sell at the market price for agricultural land. The local community development corporation, established in the early 1970s, was utilized to raise money for the project, and in just two months the purchase price was raised through donations and by selling local shares in the golf course to community members.

The layout of the golf course was designed, and local farmers donated time and equipment to help the city do the necessary construction, including building two wells, one for the clubhouse and one for the fairways and greens. A separate community golf course corporation was established, a manager–golf professional was hired, and the club was off and running! A local couple established a concession stand at the course, and the golf pro set up a pro shop. Students found work in the summers as groundskeepers and caddies, local people were now able to play (and many learned the game), and the course proved to be an attraction for out-of-town players, who found its riverside location attractive and the well-kept nine holes pleasurable to play.

Sue and Bart began to feel like an integral part of the community due to their participation in the creation of the golf course. The community has an additional asset in terms of investing in themselves, and the economic benefits to the community through the creation of new jobs and the attraction of outsiders to the community have proven to be unanticipated benefits of the project.

Community development occurred in New Richland because of the community's ability to identify its assets – including levels of bridging and bonding social capital – and to invest them in themselves. They were able to mobilize many sectors of the community to work together to make things happen. In New Richland, with its history of self-investment and community participation, such activities were relatively easy to undertake. Economic development was one of the results, but not the major motivation for the project.

In other communities, community change seems almost hopeless. New people move to town with great dreams for community improvement, but their dreams never materialize. Or local residents concerned about a declining economic base seek to attract industry, with ever-decreasing likelihood of success. What makes the difference between towns that develop and change in response to felt needs and those that seem unable to respond effectively to the current climate of economic deterioration in most rural areas? What are the components of community development, and what makes it happen?

This chapter centres on three models of community development. The assumptions behind them are followed by illustrations of how they can and have been implemented. The three models are then compared in terms of their linkages to the outside and their approaches to the planning process. Then two approaches to economic development are introduced and related to the three models of community development.

Community and Economic Development

The word 'community' comes from the Greek word for 'fellowship'. Fellowship involves interaction. Hence, *community development* implies that the quality of interaction among the people living in a locality improves over time. Such interaction both depends on and contributes to enhanced quality of life for each member of the community: better housing, better education, enhanced recreational and cultural opportunities and so on. Central to the concept of community development is the idea of *collective agency*. Collective agency is the ability of a group of people – in this case those living in the same community – to solve common problems together. For community development – and collective agency – to occur, people in a community must believe that working together can make a difference and organize to collectively address their shared needs.

Community development is much broader than economic development. Indeed, one could argue that economic development could be antithetical to community development for two reasons: economic development does not necessarily involve collective agency, and economic development may not result in an improvement of the quality of life. For instance, the high rates of economic growth in the 'boom towns' have a negative impact on community development. The incomes of some members of the community may increase, but as crime rates increase, schools become overcrowded, housing prices soar and neighbourliness declines, the quality of life for the majority of the residents may deteriorate. This is particularly true when economic growth in the community is triggered by an absentee firm, whether it is an oil or coal company, a national meatpacker, a recreational conglomerate or a transnational manufacturing company.

When we look at community development, we will focus on what local people do to improve the overall quality of life of the community. In the difficult economic times of the 1990s and 2000s, economic development was and is seen as the dominant means for community betterment. But bringing in jobs is not enough. And bringing the wrong type of jobs may decrease the community's quality of life. We will now examine approaches taken by community members and leaders to improve their collective well-being and how these approaches relate to collective agency.

Models of Community Development

Community problem solving does not take place automatically, even in a community like New Richland. Problems have to be identified, potential solutions considered, organizational means put in place and resources mobilized. There are a number of models of community development that can facilitate this happening. Let us look at alternative models of community organization to see which might serve in different types of communities.

Three major approaches to community development have been laid out by James Christenson (1989): the self-help, technical assistance and conflict models. Each of the different approaches identifies a different role for the change agent, a different orientation to task versus process, different clientele, a different image of the individual, a different conception of the basis of change, a different core problem to be addressed and a different action goal.

Self-help model

The *self-help* model emphasizes process: people within the community working together to arrive at group decisions and taking actions to improve their community. The process builds civic capacity for collective action to move toward a shared vision for the future of the community. In this model of community development, the aim is not so much to complete a particular project as to institutionalize a process of change based on building community institutions and strengthening community relationships to work toward desired future conditions. The New Richland golf course contains major elements of self-help community development because putting it into place involved reinforcing patterns of community interaction, cooperation and decision making. The change agents, the school superintendent and his wife, acted as facilitators for community input rather than sources of infinite knowledge about golf courses. People viewed the development of the golf course as something they had decided together rather than as the result of the best technical advice. The people involved in New Richland were definitely middle class. Both those who play golf and those who have the means to contribute equipment or invest in shares in a community corporation tend to be better off. And the community has developed new ways of working together to bring about an improved, shared future.

It took a while to instigate the golf course project due to the large number of meetings required to obtain everyone's input, form the appropriate committees and respond to each committee's reports and suggestions. Yet once the golf course was established, it easily became part of the public agenda in terms of local participation in running it and in convincing city government to participate in its maintenance.

However, if the New Richland project had been a purely self-help effort, the initiators would have begun with a more diffuse goal, such as increasing recreational opportunities in the community. The decision to build a golf course – or an alternative recreational facility, such as a lighted softball diamond – would have been part of the process rather than the reason for devising the process. There are a number of assumptions about the nature of rural communities behind the self-help model (discussed by Littrell and Hobbs, 1989). When these assumptions about the structure of the community are wrong, self-help as a strategy will be difficult to implement. These assumptions include these: (1) that communities' members have a similarity of interest and that community development involves building consensus, (2) that generalized participation and democratic decision making within the community are necessary and possible, and (3) that the community has a degree of autonomy such that community actors can in fact influence the community's destiny.

A central assumption in the self-help model of community development is that communities are homogeneous and based on consensus. In fact, despite the norm of 'we're all just folks' endorsed in many rural communities, most communities have increasing disparities in income and access to other resources. Thus, development efforts, which depend on existing local leaders as a basis for community organizing, may systematically bias development efforts away from the problems of the least-advantaged citizens. That bias, in turn, can give rise to increased inequalities and increasing poverty or to conflict-based community development activities. In fact, interests within communities can conflict.

Participation and democratic decision making are essential to the self-help model of development. The self-help approach assumes that it is indeed possible to motivate a broad-based band of community members to participate in community affairs. However, if community residents are uninterested and unmotivated and do not want to become involved, participation will not take place. Some groups of local residents will not see the community as relevant to their welfare, as happens, for example, with some farmers who feel their well-being depends almost entirely on government programmes. Thus, these farmers may simply bypass the community and be actively involved only in their commodity organizations, which focus on the national and not on the community level. If in a particular community no farmers are active participants in efforts to solve community problems, broad-based community participation can be said not to exist, for one important segment of the community is uninvolved.

The time commitment mandated by the self-help approach may cause many to drop out, which threatens the processual aspects of this approach. Even if the stated objectives of the community development effort are reached, the effort cannot be said to have been successful if participation in the process was minimal. The approach cannot be used to solve another community problem because no new means of interaction and quality of interaction were enhanced. In a word, the process was not institutionalized, and, from the self-help point of view, the effort was not successful. One obstacle to effective use of the self-help approach in small towns is the fact that people know each other in too many roles. Thus, the risk of taking a public stance, which is sometimes necessary for effective discussion, may result in public disagreement with a boss, a customer or a colleague. This risk is seen as too great in many small towns.

Furthermore, different segments of the community have different levels of participatory skills. Higher education and professional employment give a disproportionate voice to the more privileged segment of any community, in part because they have experience with participation. And middle-class youth are raised with verbal and discussion skills, whereas obedience – until a situation involving confrontation arises – is part of working-class socialization patterns.

Finally, self-help models of development assume a significant degree of community autonomy. Yet as we have shown in earlier chapters, rural communities are highly involved in regional, national and even international networks that have enormous impacts on them. Being dependent on the global economy, however, does not mean that it is useless for communities to undertake self-help activities. But it does make it important that the global economic trends are understood. Part of the process of the self-help model therefore includes community education on the community's place in the global economy and the current trends within it.

The case of Ivanhoe, Virginia, illustrates this point. The first effort of the Ivanhoe Civic League following its founding in the mid-1980s was to gain control of a shell building from the county government in the hope that the community would be able to attract an industry to occupy the building. Following major efforts to obtain an industry, the Civic League concluded that adult education and youth programmes would be more beneficial to the community. By the year 2003, the Ivanhoe Civic League continues to work to make Ivanhoe a better place for all of its citizens. The education programme consists of community-based Adult Basic Education/General Education Development (ABE/GED). The Ivanhoe Civic League's education programme offers college classes, youth tutorials that include guidance on college and careers, professional development workshops and computer and adult literacy classes. In 1993, a vocational component rehabilitated a historic structure in Ivanhoe to provide office and education facilities for the Ivanhoe Civic League.

The citizens of Ivanhoe decided that the assets of their community – their culture and the beautiful setting – should be shared by those who share their vision of a positive future for the community. In the mid-1990s, the Ivanhoe Civic League inaugurated the Volunteers for Communities, now a separate organization, which is currently training 17 communities throughout the region to host volunteers. Community service and celebration continue to play a major role for the Ivanhoe Civic League. They host an annual all-community Christmas party, a Thanksgiving Prayer Service and a week-long Jubilee festival, as well as many other community events. They built bonding social capital to help determine the vision and built bridging social capital to mobilize resources to be locally invested for an Ivanhoe where young people and elders prospered together.

Coaching: A new approach to self-help

Although self-help assumes that most of the assets for change will come from the inside and that the energy for change will be generated from within, a number of experiences show how coaches and facilitators can act as brokers to identify assets and passions within the community and link them with appropriate collaborators to achieve entrepreneurial visions (Sirolli, 1999) or community visions (Rubin, 2001, p497). Box 18.1 shows how coaching and a strategic visioning process helped a community college–community team move toward equitable economic development.

Technical assistance model

In contrast to the self-help model, the *technical assistance model* stresses the task that is to be performed. A few local leaders might decide that the community needs a golf course. After talking among themselves in private, they call in technical experts to assess the local situation and to find the most efficient way to build and run a golf course. The construction of the course might require receiving

Box 18.1 *A holistic approach to positive community change: The Rural Community College Initiative (RCCI)*

Southeast Community College in Cumberland, Kentucky, illustrates what team building, strategic visioning and coaching can accomplish. Southeast's RCCI employed a vision-to-action (MDC Inc, 2000) team to generate and spin off community development and education initiatives. The team includes the college president and selected faculty and staff members, business owners, a banker, a former coal miner, elected officials, grassroots leaders, K–12 teachers and administrators, and human service agency staff members. This diverse, yeasty mix of folks, who before RCCI had not worked together, has looked hard at community issues, come up with innovative ways of recombining community assets, and brought in the resources and partners needed to implement new projects.

Southeast Community College serves three counties in the heart of the Kentucky coalfields: Harlan, Bell and Letcher. Like much of Appalachia, the region suffers from the loss of mining employment, little business development and weak public schools with a low college attendance rate. A small group that has held control for years dominates local politics. The team decided to tackle these problems head-on with projects to (1) make more capital available for new business development, (2) help disadvantaged young people attend college, and (3) broaden the base of community leadership through leadership development programmes.

Southeast's work on business development finance illustrates how the college–community team provided the determination, the innovative ideas and the right mix of leadership to make things happen. The team began by holding a day-long community workshop where business and civic leaders discussed barriers to small business development in their counties and learned about development finance models from around the country. After the workshop, team member Ken Thomas, president of Harlan National Bank, and RCCI coordinator Paul Pratt talked with local banks about creating a community development corporation. Five banks signed on to form the Pine Mountain Community Development Corporation (CDC), creating a $105,000 loan fund for small businesses that could not qualify for conventional loans. The college provided a staff person (Paul Pratt) to screen loan applicants and provide technical assistance to borrowers.

The initial fund was lent out within a year, indicating a high unmet demand for microloans in the region. Building on the experience of the Pine Mountain CDC and with encouragement from the RCCI coach and team, Paul Pratt approached the numerous loan funds that serve eastern Kentucky and urged them to pay more attention to the southeastern corner of the state, an area that has been largely ignored. After two years, these conversations led to the creation of the Appalachian Development Alliance, eight development funds that will pool resources and access new sources of public and private capital for business development throughout eastern Kentucky.

Most importantly, that area of Kentucky is able to generate more income for the people who live there, as the college works to provide appropriate skills to individuals who had never thought they could finish high school, much less take college classes. By focusing on the assets of the local people rather than their deficiencies, new investments in the area began to pay off.

Source: Sarah Rubin. 2001. Rural Colleges as Catalysts for Community Change: The RCCI Experience. *Rural America* 16(2): 12–19. Also available online: http://www.ers.usda.gov/publications/ruralamerica/ra162/ra162d.pdf; accessed 16 April 2003.

government grants or finding a private investor. The consultant and the local leaders would determine the method of funding, and the site would be chosen based on objective criteria determined by experts in golf course construction. The success or failure of the project would be judged on the presence or absence of a golf course at the end of a prescribed period. The combination administrator–golf pro would be chosen on technical criteria. If a capable administrator was found, the project would continue. However, if the club pro proved inefficient or dishonest, it would be up to the town leaders (if publicly owned) or the board of directors (if privately owned), not to users of the golf course or its employees, to correct the situation. Limited oversight could then lead to limited success.

It is assumed in this approach that answers to community problems can be reached scientifically. The problems themselves are phrased in technical terms that require expert advice regarding choices among a variety of technically feasible options. This approach requires that local residents, if they desire to participate in decisions, assimilate and absorb a great deal of information concerning complex legal and scientific issues. This greatly decreases motivation to participate. A common response is to assume that there is only one technically appropriate choice and that the experts should thus be left alone to make it.

Another assumption of the technical assistance approach is that development should be evaluated based on the achievement of predetermined measurable goals. Not only is the achievement of the goal important, but so is the efficiency with which it is achieved. Cost–benefit analysis, a technical tool developed by economists to determine the ratio of costs to benefits to the public of projects, is a particularly appropriate tool for a technical assistance approach. Local citizens are defined as consumers of development, not participants in it.

Government bureaucracies are the most frequent employers of the technical assistance approach. This approach often works to the advantage of the power structure because of its agenda-setting ability. The power structure is frequently able to prevent a particular problem from reaching the level of public discussion or, in other cases, to prevent certain technically feasible solutions to a publicly defined problem from being considered as a realistic option.

An illustration of how politics and the technical assistance approach relate to one another is in industrial recruitment. Successful growth machines are able to define industrial recruitment as an essential economic development objective, especially in communities experiencing a loss of services or population. This is done by identifying industrial recruitment as the only technically feasible alternative for generating new employment through influential organizations such as the city's chamber of commerce or community development office. It may in fact be true, for example, that in a declining community where the elderly make up a high proportion of the population, transfer payments (including such things as Social Security, Medicare and Medicaid payments, as well as private pensions and health insurance payments) are a large portion of community income. A programme for the development of locally owned services used by retirees would keep that money circulating in the community and could perhaps generate more employment and greater employment stability and income than would a potential new factory. But in most cases, industrial recruitment wins out because the elderly income multiplier does not even get on the agenda. Furthermore, companies considering a move do not want it public until the decision is final. They also prefer to deal with a single person who represents the entire community. Both of these facts militate against broad community participation in efforts to recruit industry.

The conflict approach

A *conflict model* is similar to a self-help approach in that it brings people together to articulate their needs and problems, to develop indigenous leadership and to help organize viable action groups (Christenson, 1989, p37). It is different from a self-help approach in that it seeks to redistribute power. A major organizing tool is the confrontation of those seen blocking the agreed-upon solution to the problem. Using a conflict approach, a group of local people outside the local power structure would come together to discuss their problems and needs, which could include recreation and job creation. For example, as a golf course project was put forward by the elite of the town, the group seeking empowerment would mount a counter-proposal – a local swimming pool – that would also create jobs and would in addition provide recreation for the young people and poorer members of the community who could not afford golf clubs or lessons. Instead of either calling in outside experts or working in an informal fashion with local elites to mobilize local resources, the conflict-oriented group would identify a potential site and then approach the city council and the local landowner with the demand that the land be donated or purchased. The organizer would focus on building strong groups to make these demands, stressing as an important issue the lack of recreational facilities, particularly for the less-well-to-do members of the community who could not drive to other communities. Emphasis would be on the responsibility of those with power within the community – the city council and local landowners – to act responsibly in response to the needs of the community. In another conflict model scenario, once the golf course was established, the group would demand access to the course for youth, minorities and the elderly, with subsidized transportation and public equipment, so that the principle of community-wide access to collective resources would be enforced.

The conflict approach to community development has urban origins. The approach was codified by Saul Alinsky, who began as a community organizer in

Chicago in the 1930s in a Polish neighbourhood known as Back of the Yards. By working with the residents in the working-class community to identify their grievances, the organizers helped them make specific demands of the city government. This methodology has been expanded to black organizing in Chicago, Illinois; Rochester, New York; Boston, Massachusetts; Kansas City, Kansas; and Kansas City, Missouri. It has been the basis of organization of the United Farm Workers, since Cesar Chavez had trained with Alinsky's group. The Association of Community Organizations for Reform Now (ACORN), founded by Wade Rathke in 1970 based on Alinsky's organizing principles, has worked hard to implement and refine the conflict methodology. Many community organizers around the country continue to use and modify the approach, including the Land Stewardship Project that organizes farmers in Minnesota and the Industrial Areas Foundation in the colonias along the Mexican border.

Alinsky says that the world and hence any community is 'an arena of power politics moved primarily by perceived immediate self-interests' (1971, p12). Whereas the technical assistance approach views the existing power structure as having the interests of the community at heart, the conflict approach is deeply suspicious of those who have formal community power.

The conflict approach assumes that power is never given away; it always has to be taken: 'Change means movement. Movement means friction' (Alinsky 1971, p21). And friction causes heat. The goal of a conflict approach is to build a people's organization to allow those without power to gain it through direct action. Since organizations of the powerless do not have access to significant monetary resources, they must rely on their numbers. Their numerical strength is only realized through organizational strength.

Such organizations must be democratic and participatory. Alinsky believed that downtrodden people (whom he called the Have Nots, as opposed to the wealthy Haves and the Have Some, Want Mores, the middle class) acquire dignity through participation. Experiencing denial of participation is central to their being Have Nots. He saw democracy and participation instrumentally: as means, not ends. The overall ends of community organizing should be such things as equality, justice or freedom. But in an open society like that of the US, undemocratic organization by the Have Nots can negate those ends. He also placed emphasis on the learning process. Organizing should be accompanied by a conscious effort to broaden horizons. Such education then helps prevent the Have Nots, once they become Have Some, Want Mores, from acting in their immediate narrow self-interest.

Generating Community Change

Now that the basic assumptions and characteristics of each approach have been discussed, we turn to how the three approaches are implemented.

Self-help approach

The self-help approach can be implemented in many ways. One of the most common set of steps of implementation, stressed by such existing community development entities as cooperative extension services, is the social action process. The approach involves a number of steps – *visioning*, determining desired future conditions and long-term goals, using broad-based participation, determining the assets in the community, analysing alternative ways of using those assets to move toward the collective vision, choosing specific projects that move the community toward the desired future, generating community-wide commitment, planning the implementation phase, actually implementing the plan and finally evaluating. This process focuses on social capital and generally does not address political and cultural capitals. Thus, this approach often places heavy reliance on agenda setting by the existing power structure: the power structure has veto power over any proposal brought to it by the initiators.

Recognizing the cozy relationship with traditional community leaders, which this approach represents, and seeing the need for more rapid change as resource-based communities experience serious problems of out-migration, unemployment and decline of services, cooperative extension approaches have been modified so as to incorporate broad community participation in the problem-identification phase rather than waiting until the 'organizing to sell' phase. Strategic planning methodologies, *futuring* exercises, whereby a representative group from a community is asked to establish priorities based on a strategic plan and the community's mission, and 'empowerment' approaches all involve either a careful selection of representatives from a broad spectrum of organizations and occupations or an open town meeting approach to problem selection.

Technical assistance approach

In the pure technical assistance approach, a local entity, either a local government or a private entity such as a chamber of commerce, calls upon an outside expert either to develop and assess the effectiveness and efficiency of alternative solutions to a particular problem or to design the most efficient way to perform a certain task, that is, to implement a predetermined solution to a predetermined problem. In the latter instance, which represents the vast majority of technical assistance consultancies, the expert does not question the task assigned or how it was determined that the particular problem was important. The expert merely develops a plan to implement the solution.

At times, local experts, such as planners, can deliver technical assistance. They generally receive their orders from local or regional governmental officials and are involved in defining how to perform a particular task efficiently. Defining what the task should be is reserved for the politicians. Mark Lapping, Thomas Daniel and John Keller outline the steps planners should undertake for effective economic development. In the technical assistance approach, an individual with technical competence is called upon to complete each step in the process. Clearly, these steps can also contribute to the self-help approach, depending on who decides what organization or person carries out each step.

1 Gather information and data.
2 Identify the problem.
3 Analyse the problem.
4 Develop goals and objectives.
5 Identify alternative solutions.
6 Select a solution.
7 Implement the solution.
8 Enforce the plan.
9 Monitor the effort and give feedback.
10 Readjust the solution (from Lapping et al, 1989).

Conflict approach

Because of the control exercised by the existing power structure, an outside organizer going into the community generally catalyses the conflict approach. The following steps are generally followed to build a permanent, multi-issue community organization to achieve its local members' interests and link with other like-minded groups across the state and nation:

1 Community entry by outside organizer, usually at the request of local group wanting change
    1 Appraise the local leadership, looking at both formal and informal institutions in the community.
    2 Analyse the community power structure. Who has power and what are their vulnerabilities and strengths?
    3 Analyse the situation and the territory. In particular, what seem to the major objective problems, what conflicts would attempts at solution lead to and which conflicts are winnable?
2 Building a people's organization
    1 Stimulate those outside the power structure to voice their grievances. The creation of an organizing committee of community leaders and canvassing residents in their homes are both effective.
    2 Synthesize the grievances into a statement of the problem. An effective strategy for this has been neighbourhood house meetings. For the conflict approach to be effective, it must concentrate on a single issue at a time, although the organization cannot be a single-issue organization. Crucial in this process is that the issue picked for the organization to focus on be winnable.
    3 Link the problem to organizations – working with existing organizations of the disenfranchised, creating new ones and forming alliances with

potential sympathizers. The organizing process must provide opportunities to express anger and overcome fear.

3 Engage in direct action
   1 Demonstrate the value of the power of a large number of people working together to makes gains from the traditional power structure through direct action. In particular, to retain legitimacy, people's organizations need to produce a stable supply of what public administration expert Sherry Arnstein terms 'deliverables': wins that are quickly achieved and yield visible benefits wrested from political and economic institutions.
4 Formalize the people's organization
   1 Develop a permanent organizational structure, with dues and a structure that involves members in policy, financing and achievement of group goals and community improvements.

In rural areas, particularly in the Midwest, where conflict with one's neighbours is viewed as disruptive and unmannerly, the most effective use of conflict organizations appears to be in mobilizing against the outside, particularly in efforts to stop nuclear waste dumps, power lines, school consolidation, polluting industries and the like.

An example of such an organization is Save Our Cumberland Mountains (SOCM, pronounced 'sock 'em'). SOCM was established in 1972 as a dues-paying, membership-based group that employs professional organizers. The organization is centred in the Cumberland Plateau region of eastern Tennessee and in 2002 had a membership of 2000 individuals in chapters that are county or community based.

The SOCM chapter is the primary political unit of the organization. It is a non-profit Tennessee grassroots citizen's organization working on a local level for environmental, social and economic justice in areas such as forestry, strip mining, toxic issues, tax reform and dismantling racism. The various chapter groups send representatives to the larger SOCM Board or to various issue-driven steering committees, such as the legislative committee, which largely lobbies state legislators in Nashville. The SOCM Board and the various committees hold a great deal of power in the SOCM organization and plan many of the groups political activities. In order to qualify for staff assistance, the chapter groups have to show that they have been actively working on an issue that they have identified themselves, in response to some problem originating in their local community. The staff organizer works as a 'coach' for the local 'teams'. SOCM's recent successes include winning a ten-year battle to protect Fall Creek Falls State Park from devastation from acidic mine drainage by designating 61,000 acres as lands unsuitable for mining; they have also hosted their first workshop 'in house' to combat racism.

The Kentuckians for the Commonwealth (KFTC), an organization with a similar organizational structure, succeeded after many battles in stopping the strip mining of land without allowing the surface owner any rights or say in the matter, a practice springing from the *broadform mineral deed*, whereby land purchasers in the early 1900s were able to buy up hundreds of thousands of acres of mineral rights. KFTC was instrumental in getting legislation approved to set up Universal Service Funds as well as in getting the land around the historic Pine Mountain Settlement school declared off-limits to strip mining. In 2001, KFTC had its 20th anniversary.

All of these instances involved confronting an outside public or private entity in order to stop a project or policy deemed detrimental to the inhabitants of the local community. Organizers from outside the local community and support from the parent organization are important elements in the local chapter's success against such outside forces.

Factors in Effective Change

We will now examine two important factors in all three models in community development – linkages with the outside and the planning process – to see differences and similarities among the models.

Linkages for community change

None of the models of community development that we have presented deny the need to obtain outside resources in order for community development to take place. In the technical assistance and the conflict approaches, an outside person or group of people are central to the process. In both cases, an objective of the effort is often to obtain resources from the outside. The self-help approach would appear to be one that emphasizes reliance on local resources. However, as will be seen, the ability to mobilize local resources is often a proof to those who control outside resources that the self-help effort is serious. Thus, there is a complementarity between mobilizing local resources and the ability to obtain resources from outside the community. Creating strategic partnerships is necessary in all cases (Blakely and Bradshaw, 2002). This is particularly true under conditions of very limited outside resources because those who control such resources are especially keen to ensure that their funds are well spent. What better place to spend them than on a project that has shown it can obtain resources?

Financial capital from the outside is becoming more and more scarce as both federal and state governments deal with mammoth deficits by cutting funding for social programmes, including those that benefit rural communities. As the endowments of most foundations have declined with the stock market, so have possibilities of grants from both private and public sources have declined. There are a variety of state and regional venture capital funds being started by both private- and public-sector groups, which can be an important input into community development.

However, these linkages to the outside through investment can be risky in terms of the collective agency of a community. There is an old saying: 'He who pays the piper calls the tune.' This means that the source of funding, whether the federal government or a multinational corporation, can impose a large number of conditions on the delivery of capital resources. Sometimes those conditions actually cost the community more than they gain. For example, a number of studies have shown that the tax abatements, infrastructure construction and other financial incentives poured into attracting industry in the 1980s did not even pay back the local public investment, much less create wealth in the local community.

Another important type of outside linkage is less hierarchical and therefore less risky in terms of loss of collective agency: more and more communities are forming horizontal linkages with other communities that have faced and dealt with similar problems of their own. This type of lateral learning by community groups tends to foster rather than impede collective agency. Community groups analyse their own situation and consider alternative ways to confront it. Often a community member knows of another community that has faced a similar problem. Citizen-to-citizen exchanges take place as the group that has tried a solution explains both the process and the outcome to the other community.

For example, when Lexington, Nebraska, became the site of a large IBP meatpacking plant, it met with community leaders from Denison, Iowa, where IBP began as Iowa Beef Packers, and from Garden City, Kansas, where IBP's largest processing plant is located, to learn of the problems and discuss potential solutions. As part of the general move to consolidation in the food industry, IBP was purchased by Tyson Foods, Inc., in 2001. Because the communities already had links, they were better able to work together to understand the implications of the change in ownership. The acquisition by communities of information relevant to their needs through lateral learning and technical assistance can strengthen their ability to maintain collective agency when they enter into joint ventures or other means of obtaining capital from the outside in order to improve their own quality of life.

Planning as part of the change process

Increasingly, communities are recognizing that planning is a key part of development. Planning may serve any of the types of community development, but the approach to planning differs significantly according to the model of community development being pursued.

Planning is an integral part of the technical assistance model of community development. Under this model, the primary concern is with the final product, the plan, which can then be used as a map that displays the explicit tasks that must be performed. Professional planners charged with developing community planning documents may consult with the community when necessary either by talking to designated leaders, conducting surveys, or presenting results to community meetings. Community members are involved in the process not as active participants in the decision making process but as passive providers of information on which such decisions are made.

Planners then develop an overall strategy and plan of action. The plan usually consists of a baseline projection, a projection of the desired level of economic activity, and a description of ways of bringing the two projections closer together.

Once written, the plan and its implementing components can then be used to prioritize activities and eliminate options or tasks that are not included in it. In such circumstances, the plan can be used to reinforce the notion of calling on technical rather than political solutions to problems. For example, if the plan calls for a golf course, under the technical assistance model there is little need to get broad community input into the series of decisions that goes into its construction and operation.

The increasing complexity of the decisions communities are forced to make gives a great deal of power to the city engineers or administrators who are closest to the source of technical information. Their clear expertise in understanding the arcane language of, for example, zoning and taxing alternatives aids this process. Just as the city or county attorney in the past was able to dismiss a call for change by saying the proposed change was not legal (and thus forcing the person or group who wanted change to hire their own lawyer to get an alternate opinion, which they then had to take to a higher authority), now the city engineer can dismiss any change in community resource management by saying, 'It doesn't fit the plan.' At this point, the conflict model of community development becomes appropriate, for groups may mobilize to seek other experts to support an alternative action. But most often, the first 'technical' judgement goes unquestioned.

Practitioners of self-help community development favour a different version of the planning process. When conducted in a highly participatory way, planning not only allows for development of a collective vision of community but also provides mutually agreed upon signposts to help achieve it. For example, the commitment and incorporation phases of the social action approach are, respectively, the goal-setting and implementation-design phases of that planning process. But, unlike in the technical assistance model, they are imbedded within a participatory approach. Community members who participate in the social action or similar processes have some role in shaping the goals and means of implementing those goals (although as was discussed earlier, community opinion leaders may have already channelled the social action process towards certain problems and away from others). In most participatory approaches that use the self-help model, there is broad participation in determining the basic questions to be asked. The downside of the self-help approach to planning is that it is clearly more time-consuming than is the technical assistance approach.

The conflict model of community development involves a very different view of planning. Since, by definition, the conflict model is used by those who do not have power, the relationship between goals and means is less obvious than in either of the other two models. The tactical plan for implementation of goals is heavily dependent on the response of the powerful opposition to the prior actions of the group practising the conflict approach. Tactics may change from day to day. Alinsky emphasized the importance of the element of surprise in responding to those who are in power. This need for flexibility, quick response and surprise, coupled with the fact that initially the community organizer (who is usually from the outside) must be a catalyst for building an organization, are tendencies that militate toward a narrowing of decision making to a small group of people or sometimes to a single leader. However, the long-term survival and effectiveness of the organization in achieving its goals depend on broad and deep support from within the disadvantaged group. That support is best maintained through broad and active participation. So long as the organization commands few resources, participation, if not democratic decision making, is central to maintaining support for the organization. Numbers are a substitute for financial resources. Thus, there is a permanent tension in the organization or movement between democracy and centralization of control. As the organization becomes more successful in gaining resources, participation and democracy may decline unless democratic decision making processes were explicitly attended to in the organizational phase. Thus, in addition to goal setting, the strategy for organizing is a central part of the planning process for a group using the conflict approach.

Models of Economic Development

Different people have different ideas as to what is entailed by economic development. Some see economic development as identical with an increase in community income. Others view it in terms of an expansion in the number of jobs. Still others would say that economic development involves an increase in population. The relationship between community development and economic development depends on the kind of economic development that is pursued. There are a number of models for how economic development takes place. The model that members of a community adhere to influences the kind of action they undertake to bring about change. In short, there is a relationship between the kind of economic development model pursued and the kind of community development model pursued.

The firm recruitment model

One model of economic development is the firm recruitment model. It assumes that private-sector firms have considerable geographic mobility as they seek more-favourable locations. Early tactics aimed at firm recruitment during the growth years of the 1950s through the 1970s were very straightforward, involving such things as the construction of industrial sites and proactive industrial recruiting by more sophisticated cities. It was assumed that any particular locality had a series of advantages to offer and that firms would somehow find them, although by the

1970s it had become clear that despite the favourable climate for domestic industrial growth, a community had to develop a sophisticated approach to firm recruitment if it was to be successful. Planners and social scientists carried out studies to see where firms located and what they looked for when they chose new sites.

By the economic downturn of the 1980s, states and localities had begun to realize that only a few firms moved each year and that those that did usually went overseas for cheaper labour and laxer pollution controls. Competition for the few firms serious about relocating in the US became intense. States began instituting a wide variety of inducements for firms, including grants, loans, loan guarantees, tax incentives, targeted industrial revenue bond financing, tax increment financing and state enterprise zones. When one state or locality offered an incentive, others felt obliged to do so.

Less publicized but also prevalent during the 1980s were changes on the state and federal levels that weakened organized labour. Communities used low wages as a bargaining chip in attracting firms. In fact, in a number of high-growth areas where public infrastructural investments and favourable tax structures attracted industries, the jobs that were generated paid so poorly and the working conditions were so bad that immigrant workers had to be recruited to fill them. Meatpacking plants in Kansas and Nebraska are examples of this kind of industrial recruitment. Political scientist Peter Eisenger refers to these attempts to locally reduce the cost of land, labour, capital, infrastructure and taxes as 'supply side development'.

The firm recruitment model of economic development is most compatible with the technical assistance approach to community development. Local governments would hire economic development professionals to obtain grants for built capital, to develop local tax incentive packages and to recruit new firms. These activities required little grassroots participation. In fact, they are antithetical to broad-based community involvement. Getting grants requires technical knowledge of bureaucracies and procedures. Negotiations with firms that might move to the community are best carried out in secret. The firms insist on such secrecy so that communities competing for their branch plants can be played off against each other and so that their present workforce can be kept in the dark about the potential move. Firms considering a move prefer to deal with only one person who can speak for the entire community. Such approaches discourage broad community participation.

The self-development model

In contrast to this model of economic development is what Eisenger refers to as a 'demand-oriented' approach to economic development. These include the search for new markets and new products to fit those markets. Instead of simply offering incentives to any firm willing to move, public–private partnerships are formed that help determine what firms will be underwritten by the public as those with the most potential for success – and positive community impact.

One type of demand-side approach that has been effective in rural communities is the *self-development model* of economic development. This involves public-sector groups, usually a city or county government, working with private-sector groups of individuals within a community to establish a locally controlled enterprise. A national inventory of self-development projects by rural sociologists Jan Flora, Gary Green, Frederick Schmidt and Cornelia Flora identified a number of different types of self-development efforts and mechanisms through which they worked. Key to each of them was local investment of time and capital, coupled with a sound management structure and good links to outside resources of both capital and information. Although the short-term impact on the number of jobs created may not be as great as attracting a branch plant of a major multinational corporation, communities involved in self-development have found that the risk is lower and the gains more consistent than even successful industrial recruitment. Furthermore, self-development communities were more successful in attracting branch plants than were non-self-development communities. The choice to emphasize self-development did not preclude firm recruitment, although it did make the communities less likely to offer extreme tax benefits or public investments in infrastructure.

Self-development involves sustained local economic development activities. It encourages broad-based participation, involving newcomers, women and minorities. It depends on and encourages the development of community organizations. Self-development contributes to community development and it tends to encourage participation. It gives community members a feeling of control over the economic life of their communities. In short, it promotes collective agency. It is most consistent with the self-help form of community development although it can be compatible with the conflict approach.

Successful self-development models reorganize and mobilize local assets (Kretzmann and McKnight, 1993; Green and Haines, 2002; Feikema et al, 1997). Local communities and organizations that conduct asset-mapping exercises realize the power of local assets as a mobilizing tool to bring people together, as illustrated in Box 18.2.

Asset mapping is a process of discovery, of learning what is there. If carried out properly, this process will result in new patterns of interaction among community members. Discovery is most effective when it revolves around an issue.

Mapping assets, however, is not enough. There has to be commitment on the part of local people to figure out ways of recombining the assets to address the issue under discussion. The Heartland Center for Leadership Development, the Nebraska Community Foundation and the Nebraska Cooperative Extension have been engaged in important issue-oriented asset mapping as a basis for community action.

Asset mapping is important because it allows communities to move beyond a victim mentality and recognize that by working together locally, changes can be made. It means putting faith in local people to evolve a people's programme (Alinsky, 1946, p56). Asset mapping works best when communities begin by addressing pieces of issues that can be quickly alleviated. However, early success should be a learning experience on addressing the more complex aspects of the issue, such as

Box 18.2 *Holistic self-development*

In Blue Mound, Illinois, the notion of team effort is well understood. In the early 1980s, leaders in the community realized that they had to make some changes in order to better their economy. This would require extensive planning to implement all of the recommendations made for improving the community, which most towns would find difficult, if not impossible. In Blue Mound, the townspeople believed that revitalizing the town did not have to depend on financial assistance; it could be accomplished through cooperation and hard work.

In many small towns around the country, Main Street has deteriorated and in some cases disappeared. If Blue Mound did not make significant strides to bring new business into town, they would be facing a loss of their downtown. Leaders in Blue Mound soon realized that financial assistance would have to come from local residents; they could not rely on state and federal governments. Local leaders came together and devised a plan of action, sending out more than 60 letters to residents and businesses in the community to invite them to a town meeting to discuss the issues. Representatives from a local community college were also invited to participate in the discussion, which proved to be advantageous because the college had just started working with the University of Illinois–Champaign-Urbana on ways to help small communities improve their local economies.

The town meeting proved successful, and it led to several other meetings with the University of Illinois, which became interested in the project of revitalizing Blue Mound. The university provided a team of graduate students to help the village create a development programme that would extend through the year 2000. The village invested $1500, and the university absorbed the other costs. By 1983, the Blue Mound Development Corporation (BMDC) had been formed as part of the comprehensive plan that the university had designed for the community. A vision statement was formed, and numerous recommendations were laid out for the town to follow, including 'designing appropriate land use ordinances, expanding public services, improving local business and economic climate, upgrading the appearance of the downtown, improving housing and social services and strengthening the village financial condition' (Kline, 2000, p92). This farming community was able to support retail businesses and new housing, and the residents agreed that they needed to improve these elements of the town in order to attract new people to the community.

The BMDC, made up of seven people, had an annual budget of less than $1000; however, their vision did not include using money for community development. They wanted to invest people into the project so that all of the residents were part of the town's progress, and it worked. Some of their early attempts to improve businesses in the community backfired; for example, they helped the local metal-making company expand, but after it did, it moved to a bigger city. However, most ventures were a success. The local newspaper relocated to a new, larger building on Main Street after changing ownership in 1986, and after renovating its space, it had room for other businesses to move into the building. A barbershop, an attorney's office, and a golf pro shop moved into the extra space and set up their businesses. Soon after, several other businesses began moving into the downtown area, including entrepreneurs in the area.

Then BMDC began working on filling a void in the community. The residents wanted a dentist; they had had a physician in town for more than 30 years but no dentist. The board already had a connection with the University of Illinois, which made the search for a dentist a bit easier. The board knew they had to make the town look attractive and inviting to a newly graduated dentist. A young dentist who expressed interest in the town was invited to Blue Mound; the BMDC sponsored a potluck dinner, and members of the school district, local business owners, church representatives and local residents met him and invited him to come to their community. The dentist responded well to the invitation and decided to move to Blue Mound. The community wanted to help him set up his practice, and since the BMDC did not offer financial assistance, people volunteered to help. A local carpenter, plumber, electrician and other residents donated their time and skill instead of money. The dentist had a new practice in a refurbished building, and Blue Mound had completed another successful project.

Soon after the dentist moved into town, Blue Mound received a devastating blow. The local grocery store burned down, and the grocer decided to retire and not rebuild. The BMDC had to find a replacement, but none of the big grocery chains wanted to move into the small town. It became evident to the board that they would have to build the grocery store themselves, and after selling shares to local residents and leveraging those funds with a loan from a local lender, they opened the Blue Mound Store Corporation (BMSC) and hired an experienced grocer to run the business. The BMSC did so well that by the late 1990s, it had begun paying dividends to its community stockholders.

The community had several other accomplishments throughout the 1990s, including a plan for constructing senior housing, upgrading the village's water delivery system and forming a police department, which now employs a full-time police chief, two part-time officers and five auxiliary policemen. The Blue Mound police department, even though it is in a rural community, has become a state-of-the-art department and was featured in a 1992 issue of *Law and Order* magazine as a model for developing a programme entitled Dial-a-Cop. This system allows people to reach a police officer even when no one is at the station. Most of the improvement and development in the police department came from grants and resident volunteers. Because of the successful new police department, the town is now able to promote their community as being a 'safe and secure' environment, which helps attract new residents.

Blue Mound's success by the year 1998 was astounding, and it had come from a holistic effort to improve the community's economy. The key ingredients for success in Blue Mound were leadership, community support and involvement, sound planning, organization and a sense of accomplishment. Forming connections among many diverse groups of people, working toward common goals and seeing tangible results from planning efforts were all key components for successful community and economic development in Blue Mound.

unequal power within the community or long-term disinvestment in the community by public and private sectors.

Focusing on assets does not mean that a community is unaware of the impact of major social forces, including economic concentration, increasing competition, and changes in government programmes. Some see an *asset-based approach* as ignoring such issues. Although this can happen, mobilizing local resources in new ways is more likely to create a climate for successfully addressing more difficult structural issues by strengthening local social capital.

Do Communities Act?

Sociologists have long asked, ‘Do communities act?’ (Tilly, 1973). How much that happens in a community is determined by the outside and how much by the inside? Sociological research has begun to identify which communities act and under what circumstances (Logan and Molotch, 1987). These authors argue that more and more action for social change is occurring not where people work but where they live.

Summary

Community development is what people do to improve the overall quality of life in the community. Although community development often involves economic development, it implies far more. Central to the concept of community development is the concept of collective agency. Collective agency is the ability of a group of people to solve common problems together.

Contrasting three models of community development illustrates dramatically different approaches to community change. The self-help model focuses on the process by which people work together to arrive at group decisions and take action. It assumes that communities are homogeneous and consensus based. The technical assistance model focuses on the task to be accomplished and uses outside expertise to help community members accomplish that task. This model assumes that answers can be arrived at objectively, using the scientific method. The conflict model focuses on the redistribution of power among community members. It assumes that power is never given but must be taken away. Each model gives rise to a different community development strategy.

Two factors are important to all three models of community development. The first is linkages. Communities need linkages to outside sources of information. These linkages can be with external agencies or they can be with other communities, enabling lateral learning to occur. The second factor is planning. Planning is a key part of development but will be approached differently depending on the model of community development being followed.

Economic development is one part of community development. Consequently, the type of economic development strategy pursued should match the community development model used. Two of the more common models are the firm recruitment model and the self-development model. For both community development and economic development, new collaborations must be formed inside and outside communities.

Appendix: Key Terms

An *asset-based approach* to development is used by most community developers now, in contrast to the old *needs assessments*. Whereas a needs assessment focused on what was not in a community and developed a wish list of projects and programmes, an asset-based approach links the various capitals existing in a community to see how they can be recombined to achieve a desired future condition.

The *broadform mineral deed* was used by land purchasers in the early 1900s to buy up hundreds of thousands of acres of mineral rights, leaving subsequent surface owners legally helpless to prevent destruction of their homes, yards and gardens by strip mining when this technology came into vogue in the middle of the century.

Collective agency is the ability of a group of people to solve common problems together.

Community development is what people do to improve the overall quality of the community.

The *conflict model* of community development focuses on the redistribution of power among community members.

The *firm recruitment model* of economic development assumes that private-sector firms have considerable geographic mobility and seeks to engage community resources to attract those industries to the community.

Futuring is a process used by community developers and planners that brings together a small but representative group to assess the current environment, develop a strategic positioning plan and establish priorities based on the assessment and consistent with the plan and the organization's or community's mission.

The *self-development model* of economic development uses public-sector groups working with private-sector groups to establish locally owned enterprises.

The *self-help model* of community development focuses on the process by which people work together to arrive at group decisions and take action.

The *technical assistance model* of community development focuses on the task to be accomplished and uses outside expertise to help community members accomplish that task.

Visioning is a process used by community developers and planners to work with a broad-based group of citizens to determine desired future conditions and long-term goals for what their community should be.

Issues for More Sustainable Soil System Management

Norman Uphoff, Andrew S. Ball, Erick C. M. Fernandes, Hans Herren, Olivier Husson, Cheryl Palm, Jules Pretty, Nteranya Sanginga and Janice E. Thies

Assessing sustainability is more difficult than evaluating productivity because it depends on future evidence, which by definition cannot be known in the present. Certainly sustainability is an aspiration for both the first and second paradigms for soil system management. There are reasons for questioning the sustainability of Green Revolution technologies, with their heavy dependence on external inputs. Nobody can know the future prices for petroleum, which will influence the cost of energy for mechanized production and of inorganic fertilizers and many agrochemicals, but recent data give no grounds for an optimistic view of agricultural input prices. Biotechnology advances could possibly overcome the stagnation of cereal yields in most major producing countries at some time in the future, but this is uncertain.

There are no long-term or aggregate data to support any claims of sustainability for second-paradigm approaches since these are relatively new. No better claims can be made for first-paradigm agriculture. What time-series data are available on specific innovations indicate that higher yield levels with biologically based management are sustainable so long as farmers can maintain their inputs of biomass to soil systems that support and enhance levels of soil organic matter. Reduced use of inorganic fertilizers and of agrochemicals together with increased application of organic matter to the soil should have positive effects on soil biota and on associated agricultural production so long as essential nutrient levels can be sustained in soil systems. This is an empirical issue to be addressed.

1 Processes Contributing to Sustainability

As stated above and discussed below, second-paradigm approaches are not necessarily 'organic' in that they do not reject the use of inorganic inputs. Rather, there is a positive emphasis on mobilizing and managing biological processes so as to minimize the need for inorganic inputs. Yields as high or higher than those from first-paradigm practices can be attained through second-paradigm approaches, contradicting the often-assumed superiority of 'modern agricultural practices'. How sustainable alternative agricultural systems will be, and how their long-term productivity can be enhanced, are both important questions, not currently answerable.

As relatively little investment has been made in researching the alternatives to date, these questions remain to be addressed explicitly and thoroughly. Evaluations made will be more illuminating if they are undertaken not just in terms of certain hypotheses to be tested, but are linked to broader questions of how to understand soil systems and their sustainable productivity. On the basis of both research and experience, optimizing patterns and rationale for resource use should be developed and also changed over time as knowledge and feedback from practice accumulate.

It is difficult to sum up in single numbers the changes in soil systems' fertility and capabilities as these include contingent qualities such as resilience when confronted with biotic or abiotic stresses. Of particular importance for sustainable agriculture is the enhancement of soil water-holding capacity and drainage. This is very dependent on the kinds of soil biological activity that lead to better particle aggregation, creating soil that can be both better aerated and infused with water at the same time. The ability of soil systems to absorb rain run-off – to capture what Savenije (1998) has characterized as 'green water', i.e. water stored and used *in situ* – will become more and more essential in this century as variability in the timing and amount of precipitation is likely to become more extreme, which has dreadful effects on most agriculture. Acquiring and distributing 'blue water' from surface flows or groundwater reserves with all of its costs and inefficiencies in conveyance will become ever more costly. By contrast, improving soil characteristics through biological activity and management will store water, the most essential resource for agriculture, in soil horizons and root zones where it is most needed, and at lower cost.

The practices presented and evaluated in this book are recent enough that no conclusions can be firmly drawn about their sustainability. But the biological processes and effects that are being intensified or enhanced are ones that have been occurring for ages. The results of sustaining mutually productive associations between flora and fauna – specific and diverse microbial populations in the rhizosphere and in plant roots themselves – have been the production of growth-promoting hormones, beneficial meso- and macrofauna activity in the soil, biological nitrogen fixation and phosphorus solubilization, the build-up of carbon in the soil, mycorrhizal 'infection' of roots, induced systemic resistance of plants to damage by pathogens, diversified root systems in the soil that can access a larger proportion of its volume, bringing up nutrients from lower horizons of the soil to distribute on the surface and in upper layers, and reducing leaching, to list some of the most prominent.

Any one of these processes, if occurring to an extreme, can have deleterious effects, much like the overuse of inorganic fertilizer. The complexity of natural systems includes mechanisms and feedback loops for curbing excesses. Agricultural practices that fit into these flows and these mechanisms, not truncating this complexity, have better prospects for sustainability than ones that seek to set their own parameters independent of what existing systems would support. This is the challenge presented by the second paradigm.

2 Nutrients in a Soil System Context

Agricultural systems lose carbon and nutrients through the off-take of crops, but there are multiple mechanisms for restoring elements in deficit. Plants have been 'exploiting' soil resources for millions of years without depleting them because of efficient cycling and little nutrient loss. Depletion of available nutrient supplies in soil systems has been more a consequence of their management and off-take of nutrients through harvest than of natural processes.

Nutrient constraints need to be understood and remedied in terms of the supply of 'available' nutrients. Most soil systems have large stocks of nutrients in the soil that are currently 'unavailable', being bound up in recalcitrant chemical complexes or physically inaccessible. The issue for agricultural practice becomes whether rates of utilization of these 'unavailable nutrients' can meet production needs and expectations and are sustainable.

- Carbon is continuously restored to the soil through processes of photosynthesis and root exudation and through litterfall. The share of photosynthate exuded into the rhizosphere is difficult to measure and certainly varies, but plants commonly put about 10–20 per cent of the carbon they acquire from the atmosphere into the soil (Pinton et al, 2001). The amount of litterfall and crop residues returned to the system varies with system composition and management.
- Nitrogen (N) also from the atmosphere is fixed by organisms in, on and around plant roots and even on their leaves, in what is referred to as the phyllosphere, so N is restored to the soil through multiple pathways. Nitrogen is certainly abundant; the question is whether sufficient amounts in available forms can be maintained in the soil to meet crop needs, offsetting losses through leaching and denitrification as well as crop removal. Nitrogen fixation is not limited to leguminous species. Also the contributions that protozoa and nematodes make to N available in plant root zones have seldom been given the attention this process deserves.

- Phosphorus (P), often identified as a key constraint to crop production, is actually abundant in most soils, with much less than 10 per cent of the total supply 'available' at any one time. There is much potential for P solubilization and mobilization through biological processes. Turner and Haygarth (2001), in discussing their evidence that microorganisms significantly increase the P available in soil when it is alternately wetted and dried, suggest that the same mechanisms probably apply for other nutrients, but these have not been studied. It remains to be determined to what extent these processes can provide P and other nutrients at the levels and rates needed to meet crop demand and if it can be done sustainably.

There is a legitimate concern about 'where the nutrients will come from' if exogenous inputs are reduced. An ICRISAT study addressed that question and showed that organic inputs could match inorganic input-dependent practices in terms of yield, with a concomitant build-up of soil resources both chemically and biologically. A concern whether farmers can access sufficient organic resources for such production is valid but may be solvable. Relatively little scientific research and experimentation have gone into producing biomass rather than just yield. Plant breeding efforts over recent decades, aiming to maximize the Harvest Index, have sought to reduce the biomass, which can feed soil microorganisms as well as livestock. Biomass production has been raised from 6–8 t ha^{-1} to 25 t ha^{-1} in Brazil by introducing a calculated variety and sequence of plants into the system.

Significant research and experimentation have been done on N-fixing trees and on green manures and cover crops grown *in situ*. If research and extension efforts comparable with those that went into the Green Revolution were focused on the production of biomass within agricultural systems as well as on otherwise non-arable land, this nutrient and biomass constraint could, it seems likely, be alleviated creating more scope for biomass-based soil fertility management. Work would need to be done on implements such as cutting tools, shredders and equipment for transport that could raise labour productivity when handling biomass for agricultural purposes. A combination of enhanced productivity and reduced costs based on innovations that alleviate this constraint could make second-paradigm practices more profitable and would present producers with a different incentive structure in the future.

There will in most soil systems be some nutrient constraints, following von Liebig's 'law of the minimum', based on the concept that there will always be some nutritionally limiting factor operative in the soil (van der Ploeg et al, 1999). This is why the second paradigm is better characterized as 'biological' than as 'organic', since it does not reject the use of inorganic nutrient inputs.

Justus von Liebig, the first major contributor to our knowledge of soil fertility, considerably expanded his thinking by the end of his scientific career. Rather than focus on particular chemical elements in a reductionist manner, he advocated a more holistic view of soil systems and paid more attention to their living components. In 1865, reflecting on his life's work, von Liebig wrote:

> In the years 1840 to 1842, I proposed that the natural sources which deliver to plants the nitrogen they need are not sufficient for the [production] objectives of agriculture. A series of observations as well as continuous reconsideration have indicated to me, however, that this view is not correct ...
>
> For millennia, millions of people have believed, and millions believe it still, that the sun revolves around the earth because this is what they perceive. In the same way, many thousands of farmers have believed, and thousands still believe, that the practice of agriculture revolves around nitrogen, even though this belief has never been scientifically validated, and never will be scientifically supported because all progress and indeed all improvements in agriculture revolve around the soil (republished in Liebig, 1995, pp12–13; translation by Uphoff).

Von Liebig's conclusion from a lifetime of research devoted to understanding soil fertility was to emphasize the biological factors and processes within soil.

This perspective does not make chemical elements less important but rather puts them into a living context. The interactions of the components and processes of biological systems that have evolved over millennia provide a framework for comprehending and managing soil systems. This does not suggest that 'nature' cannot be improved upon. But the admonition of Leonardo da Vinci: 'Look first to Nature for the best design before invention', not only has a certain logic; a growing body of scientific evidence is explaining the merits attainable from complex relationships and biodiversity within soil systems when they are enlisted on behalf of agricultural production.

How sustainable any particular set of practices will be remains an empirical question that deserves close and continuous study. Sometimes physical interventions, such as profile modification, will enhance the soil's biological processes and capabilities. On the other hand, research has shown that one biologically oriented practice, zero-tillage, by itself is not always the best practice (Govaerts et al, 2004). Reduced tillage needs to be coupled with the use of mulch to create conditions for plant, microbial and macrofauna growth that are optimal. While these can contribute to denitrification, they contribute also N fixation. In complex systems, one seeks net positive results, as many contradictory and offsetting processes are likely to be involved. There is no reasonable basis for being opposed to 'chemical interventions' in soil systems as all of the processes discussed here involve chemicals, in various forms. While some adverse effects of certain interventions can be identified, there are at the same time various chemical interventions that can be supportive, and in many situations essential, for well-functioning agricultural soil systems.

We began this book by affirming that all soil systems have these three interactive facets – chemical, physical and biological. These are not subsystems or components, but basically coequal *dimensions* that are conjoined in time and space. Our focus and emphasis on this third facet has not tried to make it supreme but rather to restore balance to soil system analyses and prescriptions, compensating for past neglect. Everyone must recognize that there are some dynamic forces driving soil systems that come from outside, particularly climate and human interventions, while appreciating explicitly the animation of soil systems that is endogenous.

3 Some Issues for Biologically Driven Soil System Management

3.1 Optimizing the use of organic and inorganic inputs

One of the most important issues for the next decade or two as agricultural systems move toward more biologically framed management practices will be how to optimize the use of inorganic soil amendments so that there is a positive-sum effect on agricultural productivity. The principle is that of 'pump-priming', where utilizing a small amount of resources can elicit a much larger flow of desired resources. Where available soil nutrients are deficient, the practice of adding inorganic fertilizers has been conceived initially as zero-sum, compensating for a deficiency.

When inorganic nutrients are introduced into soil systems, unless sufficient organic matter is supplied to feed the soil biota and maintain levels of soil organic matter, there is often, over time, a depression of soil biotic communities and their processes that support many aspects of soil fertility. In such cases, plants in the soil become increasingly dependent on inorganic inputs, because organic inputs are diminished. A substantial amount of the nitrogen taken up by plants, by some estimates 20–40 per cent, is cycled through nematodes and other fauna that occupy middle ranks of the soil food web (Badalucco and Kuikman, 2001; Bonkowski, 2004). Much of this is forgone when inorganic amendments are made. On the other hand, there can be positive-sum dynamics when organic inputs are combined with inorganic amendments that maintain the nutrients, soil organic matter and its biological processes that underpin soil fertility.

Short-term benefits from inorganic soil amendments are common. There can also be long-term benefits such as the residual effect of phosphorus and lime applications. But the long-term productivity ensuing from such amendments should be assessed empirically rather than simply assumed. Often when soil systems have been primarily managed with inorganic nutrients (first-paradigm approaches) are switched to more biologically based systems (second-paradigm approaches), there can be a reduction in yields until the soil biological system has been redeveloped, including stocks of soil organic matter and the diversity as well as abundance of soil organisms. How to reduce the length and magnitude of such 'transitions' in agricultural systems is one of the most important and practical research questions for plant and soil scientists in the years ahead. The answers will vary, probably widely, among soil systems and for different crops. The results reported from ICRISAT are encouraging in this regard. But this remains a thoroughly empirical question. Some rough generalizations can be formulated, but actual practices need to be evaluated with both data and with sensitivity to the variability and surprises inherent in the biological realm.

3.2 Applicability to commercial agriculture

The impetus for most of the work that is reported in Part III [of *Biological Approaches to Sustainable Soil Systems*] was to identify agricultural production practices and systems that could benefit particularly the kind of impoverished, food-insecure rural households for whom Sanchez's 'second paradigm' was explicitly formulated. The needs and opportunities of these fellow citizens of the world have motivated most of the work of the editorial group throughout our lifetimes, as it has the research and practice of most of the contributors. However, what has been learned about biological approaches to enhancing soil system fertility and sustainability is similarly relevant, with appropriate modifications, to large-scale farmers practising industrialized agriculture.

High-input farming systems are of limited benefit for a majority of the world's current farmers who have low incomes and are often isolated, relating to 'the market' intermittently and seldom on very favourable terms because they lack information, bargaining power, and the essential infrastructure and institutions necessary for effective market participation. Modes of production that reduce their dependence on capital inputs and thus lower costs of production give them more opportunity to engage in market exchanges on terms that benefit them.

The vision for second-paradigm agriculture is not perpetual subsistence cultivation. Instead, it points toward various kinds of intensification that are more remunerative as well as environmentally benign, toward what Conway (1999) has dubbed 'the doubly green revolution'. Recently, UN secretary-general Kofi Annan has called for 'a uniquely African "green revolution" for the 21st century' (Annan, 2004). We expect that this will depend heavily on the kinds of innovations discussed in this book. When looking for good examples of productive new approaches for Part III [of *Biological Approaches to Sustainable Soil Systems*], it was gratifying to see that more than half of the chapters written were based entirely or in large part on work going on in Africa. This is an encouraging statistic. Moreover, for small-scale farmers the increases in profitability accompanying more biologically based production methods can be even greater than the changes in output, so the socioeconomic benefits from these methods can be more than the agronomic and environmental ones.

Larger commercial farmers are, at the same time, experiencing cost-price squeezes that are eroding the profitability even of large-scale operations. The globalization of commodity markets is making even big producers subject to the vagaries of the market. These larger producers are supported by over \$1 billion day^{-1} of governmental subsidies, meaning that taxpayers in the richer countries are encouraging and paying for these inefficiencies. They also have serious negative externalities for small-scale producers in poorer countries.

As global climatic influences become more variable and extreme, the vagaries of weather further complicate those of market forces. The more capital that farmers have invested in their operation, the more vulnerable they become to shifts that benefit consumers at the expense of producers. Cultivating robust soil systems that can better withstand the effects of drought and flooding, through better water-holding capacities and better aggregation, will become more and more relevant to commercial agriculturists, whose large capital investments and debt hold them hostage to climatic stresses.

More immediately, environmental and health considerations are likely to begin shifting current calculations as regulations constrain the timing, amounts and kind of inorganic fertilization that can be used, and the application of pesticides. Consumers' concerns about their exposure to agrochemicals and residues have made organic agriculture the fastest growing part of the agricultural sector. Worldwide demand for organic products is rising approximately 20 per cent per annum, as reported in *Nature* (22 April 2004). While scientific evidence on the health benefits of organic food products is still mixed and thus contested, the main uncertainty is over whether benefits are as great as proponents claim, with no support for the converse conclusion that food grown with synthetic inputs is better for human health than that produced 'organically'. As long as there is rising consumer demand and it is profitable to move toward sustainable agriculture practices – as some large commercial producers such as Dole and Unilever have begun to do – the appeal of more biologically based agriculture will continue to grow.

3.3 Some constraints to be addressed

Labour intensity

One limitation on many biologically based practices has been their relative labour-intensity, although some like direct seeding through permanent vegetative cover and green manures and cover crops are labour-saving from the start. Mechanized, energy-intensive agriculture was developed to enhance farm profitability by reducing labour requirements. The cost of labour is rising around the world; but so are the prices for fuel and agrochemical inputs. The low prices for petroleum that supported agricultural as well as industrial expansion in the latter part of the 20th century are probably now 'history'.

The economic logic of technical change charted by Hayami and Ruttan (1985) will sooner or later begin reflecting the greater relative scarcity of productive land and the rising costs of fossil fuel-based inputs, and their transportation, even as labour costs continue to rise. Especially in developing countries, the relative availability of labour will continue to influence factor markets.

By expanding units of production in the past, profits could be enhanced by economies of size, not just of scale. (Economies of size derive from economic advantages that are due to greater bargaining power in the market; economies of scale reflect gains from more efficient resource use.) Indeed, the productivity of land usually declines in larger-scale operations as soil systems are less carefully managed, as labour and capital are applied across larger areas.

In this century, as population continues to grow, even if the rate of growth is slowing, previous strategies that use land profligately will become less viable as the relative availability of good land per capita diminishes. Actually, if the current system of agricultural subsidies in rich countries were eliminated, this would rapidly transform the capital- and chemical-intensive nature of their agricultural production, which has been favoured by policies rather than by market-determined price structures. In the future, it will probably become economic to apply more labour to land, provided this is done productively, rather than continuing to rely on land-extensive strategies. Various methods and systems that have been documented in Part III [of *Biological Approaches to Sustainable Soil Systems*] can help with such a transition.

Some biological innovations are not necessarily more labour-intensive, e.g. soil inoculations and direct seeding with no-till. The latter saves fuel as well as the labour and other costs of plowing and weeding, which is why it is spreading in Latin America, North America, Europe and South Asia. Others methods like the System of Rice Intensification (SRI) and composting may require more labour, but to the extent that they give higher per-hour returns to labour, they are economically attractive, and with time and experience as well as mechanical innovations, their labour time is reduced.

Most of the technologies heretofore identified as labour-intensive did not offer high returns to labour. Labour has been used abundantly, even excessively where it was cheap, to make land, capital or water more productive. This necessarily diminished labour productivity. Because second-paradigm methods are mobilizing resources from the soil or atmosphere through essentially free (unpaid) biological activity, it is possible to have higher labour productivity at the same time that labour inputs are increased, i.e. with greater labour intensity. If this is a more profitable use of labour, it can become attractive to farm households and to investors even if more labour is required. The limitation will then be whether sufficient labour supply is available to take advantage of the opportunities (Moser and Barrett, 2003).

Biologically oriented methods are not necessarily limited to a small scale. SRI, for example, is being practised on a larger scale, not limited to smallholdings, now that its methods are being better understood. Good organization of cultivation practices is required, but an increased requirement for labour could benefit both the farmer and hired labourers. Actually, the SRI methodology is proving to be labour neutral or even labour-saving once farmers gain familiarity with its techniques (Anthofer, 2004; Li et al, 2005; Sinha and Talati, 2005). Whether alternative technologies will in the long run require more labour is still an open question. Not all of them will be equally dependent on more labour inputs. In any case, what is more important is whether and how much they can raise labour productivity.

Many of the innovations reported in this book as they are scaled up and as farmers, scientists and extensionists gain experience with them, will have labour-saving modifications that diminish this constraint to wider adoption. A main constraint for the spread of conservation agriculture (no-till) has been the availability of suitable implements. As the designs for tools, equipment and implements become better suited to farmers' conditions and as the production and supply of these are ramped up, with concomitant reductions in price, the acceptability and spread of biological innovations should be hastened.

Biomass

A constraint that can be critical for many of these biologically driven innovations is the availability of biomass for keeping soil energy and nutrient stocks sufficient to support higher levels of biological activity. The use of fast-growing leguminous trees and cover crops presents varied opportunities for increasing biomass and also enhancing N supplies in the soil. Finding ways and means to grow more abundant biomass on presently uncultivated land, with techniques that are environmentally benign and labour-efficient, is one of the most important areas for research in support of various biologically driven approaches. Complementing this are the production and use of bioproducts such as compost and inoculants that enhance the productivity of organic and other inputs.

As noted above, little thought and little investment have been devoted to reducing biomass production as a constraint. As long as the returns to making organic inputs are moderate to low, there is little incentive for researchers or farmers to tackle this problem. But the kind of productivity and profitability gains that are documented in Uphoff et al (2006) should make this an attractive area for experimentation, including the design and production of tools and transport equipment that can enhance labour productivity. The work of CIRAD and its partners in Brazil and Madagascar has shown, for instance, that there are some plants that can grow very well in dry or cold seasons and have aggressive rooting systems that improve soil structure. These can produce large amounts of biomass when there are no crops being grown. This means that there is little or no opportunity cost in terms of agricultural output and, instead, a substantial augmentation of production when these plants are utilized to increase soil organic matter and improve physical characteristics.

Further, as noted above, inorganic nutrients can often be productively used to increase biomass output. No opposition or mutual exclusion between organic and inorganic inputs should be erected that leads to a suboptimization that is not in the interest of farmers or of sustainable soil systems. Soil and climatic constraints have been the major physical limitations on agricultural production in the past. Inorganic inputs that help to increase organic outputs can diminish both constraints. By creating better soil conditions and root systems, they can even offset some of the constraints of rainfall and temperature by holding water and buffering heat or cold.

The production of compost on a commercial basis, and especially of vermicompost, is expanding in India and other countries. The production of biofertilizers and agents for biological control of pests and diseases is being taken down to the village level, so that employment is created at the same time that farmers using these bioproducts get higher output and profits. Unlike the production of biomass, manufacturing these products does not require any access to land. The same is true for production of bacterial or fungal inoculants, which have the effect of 'producing more land' by raising the productivity of existing cultivated area. These are innovations well suited for the 21st century. Biologically based agriculture will, it appears, be increasingly integrated into commercial production activities at both large and small scale as part of future agriculture.

Training

Because these new approaches are knowledge-intensive, and require some changing of mindset as well as having factual information, a principal constraint for their spread is a lack of understanding not just of techniques but also of rationale and principles. The practices being proposed often go against what has been taught in schools and universities for 150 years. Yet they are supported by a huge amount of research and now-spreading practice.

Training is probably too narrow a concept for what is needed, though the substance of biologically based agricultural thinking should be incorporated into training programs around the world. These new practices represent a shift in paradigm, from input-dependent, exogenously focused production systems to ones that are soil-system-based and endogenously focused. They adopt an ecological perspective that appreciates the interactions among organisms, seeking to maximize positive synergies and to control or eliminate negative effects. The expanding field of biotechnology can become compatible with this perspective if it becomes less preoccupied with manipulating the genotypes of individual species and appreciates more the interaction among species. Genes are of course important, but a genocentric view of biology is being superseded by concerns with G × E interdependence, studying genetic interactions with environment. Thus, the relearning is not just for farmers but also for scientists and extension workers.

4 New Directions for Agriculture in the 21st Century

Brazil is a country held up as a paragon of modern agriculture, with a dynamic and productive agricultural sector, expanding through many large-scale operations. Yet as seen in Uphoff et al (2006), it is also a country where some of the most interesting large-scale applications of the new, biologically based thinking about agricultural improvement can be found (Boddey et al, 2003). Brazil is a country where agriculture is not subsidized as in North America and Europe. Indeed, it faces significant disadvantages of transportation costs given its global location and the location of many of its farming areas. Still, Brazil is becoming more and more competitive in the world market.

The area under newer systems of production has now reached at least 22 million ha in Brazil, growing by 1–2 million ha yr^{-1}. Use of conservation agriculture techniques has spread even faster in the US, more than doubling between 1997 and 2003 and now covering an area 50 per cent more than in Brazil, according to Derpsch and Benites (2004). Some of the 'negative externalities' of Brazil's modern agriculture, employing a high degree of mechanization and soil tillage along with heavy inputs of mineral fertilizers and agrochemicals, are becoming too great to be ignored, with adverse impacts on soil quality and microclimates. The rising economic costs of conventional production methods are pushing Brazilian farmers to reevaluate their technical options.

Research on different approaches to soil system management is cumulating across many countries, building upon decades of basic research conducted while most investigations were still being carried out within the context of the first paradigm. It is surprising to see how many of the seminal scientific studies published on phytohormones, mycorrhizal associations and nitrogen cycling through protozoa and nematodes, to take just three examples, were done in the 1950s, 1960s and 1970s, with little attention paid to them. However, this work has persisted and matured over the past 50 years, strengthened now by new analytical techniques, many at the molecular level, giving clearer outlines and more specificity to the actors and processes in the soil food web that have been amorphous and inexact. Their consequences for plant/crop performance and for agroecosystem functioning are becoming better known.

4.1 Rationale for new directions

The factors making the second paradigm more salient and attractive are numerous, going beyond the accumulation of scientific knowledge that offers explanations for the beneficial effects observed and measured. These include the following:

- Changing factor proportions – Land per capita ratios will require raising land productivity through more intensive, i.e. less extensive, production strategies as labour supply relative to land will continue to increase. Whether labour in the agricultural sector becomes more productive will depend on the technological and institutional configurations that this century evolves. The scientific basis for enhanced land and labour productivity through intensive management of plants, soil, water and nutrients is available and growing. Especially more productive utilization of freshwater resources will become imperative in many countries and regions, making the enhancement of root growth and soil biotic communities more essential.
- Calculations of real cost are changing as environmental 'externalities' get figured into societal if not always individual assessments (Pretty et al, 2000; Pretty, 2005; Tegtmeier and Duffy, 2005). Groundwater and soil contamination from N fertilizers and agrochemicals is increasingly subject to regulation while the economic costs of their use become relatively greater. Economic and environmental considerations are favouring movement toward management strategies relying more upon intrinsic biological and ecological processes.
- The disgrace of poverty and hunger that still afflict too many people on our planet suggests that new approaches are called for in the agricultural sector, where, ironically, most of the world's hunger is still concentrated. External input-dependent technologies continue to bypass the poor. Biological technologies can be adapted to the conditions of resource-limited households and can be made to benefit producers and consumers.

The argument that synthetic external inputs are necessary to 'feed the planet' (Avery, 1995) is contradicted by the evidence presented in Uphoff et al (2006). Biologically based agriculture that combines the use of organic and inorganic inputs can match or surpass first-paradigm agriculture. It should be possible to produce more surpluses to meet the food needs of the urban poor with more intensive methods given their demonstrated potentials.

Also, the lower costs of production with these methods can make them more profitable for the poor and also reduce risks of loss when less capital investment is required. This was seen in an evaluation by IWMI-India of SRI adoption by impoverished farmers in West Bengal. Even with only partial use of the recommended methods, yields for 110 farmers using both methods were 32 per cent higher on their SRI plots, while their net profits ha^{-1} were 67 per cent higher because costs of production were lower (Sinha and Talati, 2005). Concerns with poverty reduction and food security add to the rationale for taking the second paradigm seriously.

4.2 Paradigm change

As stated at the outset of the chapter, we do not expect one paradigm to replace the other. That is not how the history of interaction between ideas and practice has occurred. However, as new paradigms gain credence and influence based on accumulating evidence in their favour, eventually new combinations of practice emerge that suit both the ideas and the objective conditions as well as the needs of those people who are engaged in the application of available knowledge. The second paradigm is still in its early stages of development, although it is now much more fleshed out and robust than when it was proposed ten years ago.

There is need for continuing and expanded research to validate and vary the principles and conclusions upon which it is based. But this is not a case where science will first create new opportunities, and then technological applications will be derived from the emergent knowledge. Much of the knowledge base for the second paradigm has been emerging from practice, with scientists then investigating the new ideas and opportunities with their standard methods of analysis. A two-track rather than a sequential approach is indicated for this domain, as there is already enough evidence and scientific justification for application and refinement of second-paradigm thinking, supported by government extension services, NGOs and farmer organizations. Concurrently, researchers have a huge and promising research agenda before them framed by the second paradigm. Pursuing the questions it raises should give higher returns to research investments at the margin than continuing with more thoroughly investigated questions deriving from the first paradigm.

4.3 Knowledge-driven change

Uphoff et al (2006) was written for researchers who have a direct interest in practice and for practitioners who appreciate the fruits of research. We have tried to meet high academic and scientific standards, but the motivating concern was to produce and share knowledge of practical value. The contributions have been intended to speak to the interests and needs of persons who are seeking to get most, and most sustainable, benefits from the resources available to the agricultural sector and for the producers within it, including particularly the most resource-limited ones.

More productive and sustainable strategies will derive from a thorough knowledge and appreciation of the biological nature of soil systems. These are shaped by physical characteristics, and their transactions are made in the coin of chemistry. But the fundamental determinants of fertility remain the soil biota that have coevolved symbiotically with plant root systems and with plant shoots and animals above ground for 400 million years.

This reality can be overlooked but it cannot be repealed. It can be compensated for, if undercut, by use of external inputs. Such a strategy can be and often has been successful, and it will continue to be beneficial in many places for many farmers, but its productivity is abating. Fortunately, the opportunities that postmodern agriculture is opening up in the 21st century are not limited to either richer or poorer farmers. The ubiquity and synergy of genetic potentials in plants and soil organisms is widely and freely available to all those who understand and respect them.

Farming With the Wild: Foreword and Introduction

Fred Kirschenmann and Daniel Imhoff

Foreword

Fred Kirschenmann

As a farmer, my relationship with wild things has been fraught with ambiguity. I grew up believing that wildness was the enemy of agriculture. I didn't like blackbirds eating our sunflowers, coyotes attacking our calves, or weeds robbing our crops of nutrients and moisture. So I had an almost instinctive inclination to tear all the wild-ness out of our farm. I was ready to use all the tools or scientific management tactics available to eradicate wild things from the farm.

A part of me even felt morally justified in harbouring that attitude because it is deeply entrenched in our culture. The early Puritans who settled on New England's shores considered it part of their manifest destiny to 'tame the wilderness' and 'build the Kingdom of God' in this 'new land'. Cotton Mather (1663–1728) considered the wilderness to be the 'devil's playground'. It was, therefore, part of his God-given responsibility to urge his fellow Puritans to replace the wilderness with nice, neat rows of corn. For good or ill, that Puritan ethic shaped much of the culture in North America once Native Americans were driven from the land. I am a product of that culture.

Like the generations of farmers and ranchers before me, I have lived, in part, by this wilderness eradication ethic and caused devastating harm to natural ecosystems. Meanwhile, conservationists have adopted a countervailing ethic in order to protect the wilderness. In response to centuries of abuse, conservationists decided to preserve wilderness in its natural state by designating certain regions as Wilderness Areas that are to be protected from human activity. Only with great difficulty have wilderness advocates managed to keep a small proportion of our country

(approximately 5 per cent) free from industrial intrusions (though not free of livestock). But by quarantining humans from certain parts of the landscape to preserve it, we have also inadvertently consented to humans using the rest of the landscape without any regard for its wildness.

We now know that this dual approach to land use is dysfunctional on both counts. Wildness cannot be 'maintained' in the form of isolated pieces of the landscape, and farms cannot be productively managed without wildness. Just as wild organisms need the connectivity of natural ecosystems to thrive, so agriculture needs the wildness of soil organisms to maintain soil quality and pollinators to grow crops – both necessary elements for productive farming. So in the interests of both productive farming and robust wilderness, we need to revisit our dualistic mentality.

Since producing as much as possible in one part of the landscape while preserving everything in its natural state in another part of the landscape is not working, and the real goals of conservation – preserving the integrity, stability and beauty of the biotic community – have been betrayed, we are now forced to come to terms with our fundamental role as *Homo sapiens* within the biotic community. The essential fallacy in our dualistic thinking is that in both cases – wilderness and agriculture – we had assumed that humans were separate from Nature. Isolating wilderness areas from human activity assumes that wilderness thrives best without human intervention. Indeed, large areas uninhabited by people such as the Brooks Range of Alaska provide powerful testament. That assumption, however, while probably true in the modern, industrial context, serves only to deepen the schism between humans and wild Nature. Isolating wildness from agricultural landscapes presumes that humans, acting separately from Nature, can control production systems purely with human ingenuity and technology. Neither assumption encourages the sort of healthy reintegration into the biotic community that humans must achieve – for our own sake and the sake of all life on Earth. Behind that dualistic fallacy lies another, namely that Nature is a given, that it has evolved into a state of equilibrium (that it will remain essentially the same) and that we can either manipulate it at will (agriculture) or preserve it in a natural stasis (wilderness). Again, there are no empirical data to justify such assumptions. And this both encourages the alienation of humans from Nature and represents a serious underestimation of Nature.

Fifty years ago Aldo Leopold attempted to overcome this flawed dualistic thinking by introducing a new paradigm – an 'ecological consciousness'. The role of *Homo sapiens*, he suggested, had to be changed from one of 'conqueror of the land-community to plain member and citizen of it'. This way of thinking, he suggested, transforms our relationship within Nature. It:

> reflects the existence of an ecological conscience, and this in turn reflects a conviction of individual responsibility for the health of the land. Health is the capacity of the land for self-renewal. Conservation is our effort to understand and preserve this capacity (Leopold, 1949).

When our understanding stems from this perspective, the boundaries between domesticated agriculture and wilderness begin to soften.

Our society's failure to appreciate the need for an ecological consciousness is evident not only on industrial farms, but on organic farms as well. We have, unfortunately, come to think of organic farms as isolated enclaves that have little or no connection with the ecology of the landscape in which those farms exist. Organic farms, treated as isolated enclaves, cannot maintain the rich biodiversity necessary for a healthy farm, any more than an isolated wilderness can preserve the biodiversity of a healthy ecosystem. If we hope to create an agriculture that ensures the land's capacity for self-renewal, or a wilderness that perpetuates the native biodiversity of a region, then humans who possess an ecological consciousness need to be part of the landscape.

It is, in part, our dualistic thinking that has led us to believe that the 'environment' exists of its own accord. It is just 'out there'. In truth, however, the environment is constantly being constructed by the organisms (including humans) who live in it. As Harvard evolutionary biologist Richard Lewontin (2000) reminds us, all organisms:

> are in a constant process of altering their environment. Every species, not only *Homo sapiens*, is in the process of destroying its own environment by using resources that are in short supply and transforming them into a form that cannot be used again by the individuals of the species.

In other words, if it were not for the activity of organisms in nature modifying their environment – and in doing so, destroying part of it – there would be no environment.

It is the process of one species destroying part of the environment that creates opportunities for other species. Cows eat grass, thereby destroying part of the environment. The by-product of that activity is manure, which provides food for dung beetles and other organisms, who in turn destroy the manure, and in so doing create nutrients for the soil to produce more grass. As Lewontin (2000) goes on to say, 'every act of consumption is also an act of production'. The appropriate role of humans, then, is to engage in a dance with other species in the biotic community in a manner that enables the community to renew itself – both its wild and domestic parts.

Applying such a view to 21st century agriculture will require a radical shift in our relationship with Nature. First and foremost, we must reclaim our solidarity with the ecosystems in which we farm through 'place-based reinhabitation'. As David Abrams has written: 'It is only at the scale of our direct, sensory interactions with the land around us that we can appropriately notice and respond to the immediate needs of the living world' (Abrams, 1996). Our mission as farmers and ranchers then, must evolve from providing adequate, affordable, nutritious food and practising good conservation to taking direct responsibility for the 'health of the land'. Our conception of science must change from one that invents technological innovations to solve human problems to sciences that engage in locally based conversations with Nature. Our notions of organic farms must change from enclaves of purity to habitats within ecosystems. The certification of individual farms must give way to standards and monitoring systems for certifying entire watersheds. At that point, agriculture's relationship to wildness will move from production enclaves to wild farm alliances and restoring interconnected healthy ecosystems.

On our own organic farm in North Dakota we have begun to appreciate the role of wild-ness in productive farming. We now use livestock breeds that have retained some of their 'wildness' and as a result our beef cows possess the instinct to protect their calves from coyotes until the youngsters are old enough to fend for themselves. We have discovered that maintaining a suitable habitat for pollinators and beneficial insects increases the productivity of our cropping system. By mimicking the 'succession' inherent in wild systems with crop rotations, we have eliminated the need for costly herbicides to control weeds. We hope that someday perennial polycultures will replace annual crops, eliminating the need for annual disturbance of agricultural lands. We are convinced that many additional benefits lie hidden in the vast resources of the prairie ecology in which we farm. Despite decades of research and education devoted to controlling Nature, we have a lot of catching up to do. We first need to comprehend how the prairie ecology functions so that we can better understand how to farm by accessing Nature's free ecosystem services while improving the land's capacity to renew itself. Once we achieve that understanding, our farm will become more profitable and more sustainable.

Given the depletion of fossil fuel resources, the inabilities of our farming regions to sustain any further agriculture-related degradation, our expanding human population and its impacts on biodiversity, many of the above changes will take place. But this will require that we abandon our dualistic thinking, adopt an ecological consciousness and erase the hard boundaries between tame and wild in our minds.

The Case for Farming with the Wild

Daniel Imhoff

On a rural roadside just north of Winters, California, with the summer sun so hot the air shimmers like a mirage, we stand between two radically different farming philosophies. Miles away to the west are the tawny and creviced hills that drain the wet-season rainfall of the Pacific Coast Range. Those waters eventually make their way to the Union School Slough, now actually a volume-controlled ditch, which meanders eastward through the irrigated row crops, orchards and livestock pastures of Yolo County. On the western side of the road, you get a sense of time travel, a feeling of what the land may have looked like in a former era. The bunch grasses and sedges that line the canal banks are bushy, tall and luminous. Farther out, above the understory, rises a canopy forest of willow, cottonwood and oak. In the water, a paddle of young mallards shadows their mother as she zooms for cover behind a curtain of grass.

Directly across the road to the east is a scene more typical of industrial agriculture in California's Central and Sacramento Valleys. The 180-degree shift is so dramatic that it almost takes your breath away. Between the field edge and the slough, a distance of perhaps 20 feet that includes a single-track dirt lane, the soil is sprayed and scraped bare and, in contrast to the scene just on the other side of County Road 89, looks like scorched earth. Both sides of the road are working farm operations that depend upon the Slough's water for production. It is early summer, and both farmers are in high production mode, weeding, irrigating and managing a hundred tasks. Just a few decades ago, I am told by the farmer on the west side, he too practised 'clean' farming and viewed weeds and non-crop vegetation as mortal enemies of modern agriculture. But as a Boy Scout leader he had studied conservation principles, and as a wildlife veterinarian he had visited hedgerows in England during a trip abroad. Not long after, he and his wife decided to begin improving wildlife habitat on their 500-acre farm, bringing its edges back to life. He devoted himself to studying California's original oak savanna and local ecosystems and began to establish seasonal wetlands and tailwater ponds to filter run-off. Eventually, some 50 species of native perennial grasses, forbs, rushes, shrubs and trees were planted around field borders, roadsides, riparian areas and other unused strips of the farm. Two decades later, beavers, carnivores, dozens of bird species including three types of owls, and up to ten threatened or endangered species find haven there. What he didn't realize at the time, was that he was also sowing the seeds for a change in agriculture itself. What looks like a move backward in time allowed him to move forward as both a farmer and lover of the land. Due in large part to his initiative, a community of conservation-minded farmers, local agencies and extension officers, and nonprofits has slowly been building the expertise, resources and momentum necessary to forge a new approach to farming in the region.

Across the country throughout the 1990s, similar discoveries, similar commitments, similar reversals of vision were occurring in widely separated areas. The essential role of native pollinators in local ecosystems and in agriculture and the crisis of their rapidly vanishing habitat were being researched in the Arizona desert. Native plant aficionados were seeking out remnants of prairies and beginning to collect, save and grow out seed for local restoration projects. After decades of clearing, draining and attempting to render marginal lands suitable for cultivation to 'feed the world', federal agencies were working with farmers to return those same fields to wetlands, grasslands and bottomland forests through perpetual easements. Partnerships between farmers, rod and gun clubs, land trust organizations and environmentalists were forming to carefully time farming practices with the migratory pulses of waterfowl and fish. Natural processes of flood and stream flow were being reintroduced into a few select riverside agricultural areas in California while lightning-ignited wildfires were being welcomed on a million-acre tract of grasslands in the New Mexico–Arizona–Mexico Bootheel region – both as means of regenerating the land. A few ranchers were making peace with large carnivores, while some dairy and beef farmers were bucking the livestock feedlot model and perfecting the art of small-scale rotational pasture systems. A Kansas geneticist was pursuing a vision of creating, through classical plant breeding, a self-seeding prairie of perennial grains that would require little fertilizer and no tilling, ideally adapted to its place on the land. The reassemblage of former free-roaming grassland species such as the bison, prairie dog, ferret, wolf and elk was beginning to take nascent shape in fragmented areas of the Great Plains. Throughout the mid-elevation coffee farms of Central America, biologists were discovering the critical link between habitat remaining on forest-shaded coffee farms and declining populations of migratory songbirds. There are more examples, many more, of people tuning in to both the small picture of their own farms and ranches and to the broader landscape, working in partnership with, rather than against, the surrounding natural world. It is time to give a name to what can only be described as a gathering movement: *fanning with the wild*.

This book has been the result of a multi-year research project to document and chronicle on-the-ground efforts to restore wild habitats within farming and ranching regions across the country. My interest in taking on such a challenging topic came from various personal experiences and sources of inspiration throughout the 1990s. As the owner of a remote 100-year-old apple orchard in Northern California's Anderson Valley, one frequented by wild turkeys, bobcats, screech owls, gophers, pileated woodpeckers, black bears (who eat fruit by the limb and must be discouraged if harvests are to be sustained), as well as an additional cast of wildlife too numerous to list, I was naturally inclined. As a freelance writer who reported on the organic industry for many years, I ultimately became convinced that the standards set for organic farm management had not necessarily taken into account a farm's impact on its watershed and surrounding ecosystems. One particular assignment for *Whole Earth Magazine* triggered a host of questions that led me to write further articles in *Sierra* and *Orion Afield*. Finally, as a part-time activist who had attended numerous presentations about the need for wildlands connectivity across the landscape, I encouraged John Davis and Mark Ritchie, programme officers at the Foundation for Deep Ecology, and Paula MacKay of the Wildlands Project to help me organize and host a conference on the topic. Held in January 2000, the small retreat resulted in the formation of the Wild Farm Alliance, now led by a nationally placed steering committee and advisory board of farmers, naturalists, educators, writers, gardeners and others that spend copious hours each month discussing the successes and shortcomings of promoting agricultural systems that are truly compatible with the full range of wild Nature. The need to produce a book that could help further the establishment of conservation communities across the country emerged as key tool for the organization. I eagerly volunteered and convinced my long-time collaborator, photographer and graphic designer Roberto Carra, to join me. Our hope was to assemble a vision of what interconnected, fully functional ecosystems and healthy farming communities might look like. We wanted to focus on positive examples rather than problems, and we wanted to keep our standards rigorous. Two years, 21 states and two countries later, we present what we hope is a unique yet inspiring view of the American landscape.

Industrial agriculture and the biodiversity crisis

At first glance, the phrase 'farming with the wild' may seem contradictory. Agriculture, by its very nature, has been and remains the relentless process of selection and minimization, one that now blankets billions of the Earth's acres with a mere handful of crops. Farming and ranching activities are consistently identified as the primary cause of habitat loss, the arch foe of the biodiversity crisis. Some 10,000 years ago, out of the cereal-bearing grasslands of the Fertile Crescent, out of the apple forested mountains of Kazakstan, out of the planet's 200,000-plus wild plant species and nearly 150 large wild mammalian terrestrial herbivores and omnivores – slowly and yet almost all of a sudden – there emerged the beginnings of what we now know of as the domestic (Diamond, 1997, p132). Ever since, agriculturalists have been diminishing native biodiversity in order to repopulate landscapes with utilitarian or desirable species. Size, sweetness, oiliness, fibre length, ease of cultivation, hardiness and vigour, self-pollination, yield, taste, nutrition, perishability, healing and recreational properties, colour: these were many of the lures for early agriculturalists as they developed place-based cropping systems. Throughout the millennia, agricultural domestication has largely been a dance of co-evolution, with humankind playing a leading role as artificial selector and steward, among a full cast of essential and cooperative participants (including birds, insects, fellow mammals, grasses, pulses, food and fibre plants and natural systems).

Many reaches we tend to imagine as wilderness – self-regulating and self-sufficient natural areas – may in fact have never been as completely free of human influence as we might think. First American societies were intensively managing some, but certainly not all, areas of the native landscape, using fire, for example, as a primary tool in maintaining open and vital grasslands. Yet through the conquest of the native landscape, the continental domination of European agriculture, and the rise of the global-industrial economy, never have the distances between farming and wildness been so vast or the human impacts on biodiversity so damaging. As Michael Pollan states solemnly in *The Botany of Desire: A Plant's-Eye View of the World:* 'Even the dream of such a space has become hard to sustain in a time of global warming, ozone holes, and technologies that allow us to modify life at the genetic level – one of the wild's last redoubts. Partly by default, partly by design, all of nature is now in the process of being domesticated – of coming, or finding itself, under the (somewhat leaky) roof of civilization. Indeed, even the wild now depends on civilization for its survival' (Pollan, 2001, pxxiii). This is a chilling realization and a far remove from Henry David Thoreau's edict that 'in wildness is the preservation of the world'.

At one time, thousands of plants were used for human food and agriculture. Today, no more than 120 plants provide 90 per cent of plant-supplied human food, oil and fibre needs; a mere dozen account for 80 per cent of the modern world's annual tonnage of all crops (Diamond, 1997, p132). In the 500-year period starting with Columbus's first voyage to the New World, colonization and world trade have transformed the biology and cultures of the Earth at dizzying speeds. It is hard to imagine that tomatoes were not a native element of Italian cuisine, that pre-Colombian Mexican food had no cheese, that Thai food's spicy chiles were adopted from Central America, or that potatoes were strictly South American and coffee East African. In the US, however, 98 per cent of the food production can be attributed to non-native species such as wheat, corn and cattle (Baskin, 2002, p26). According to Peter Vitousek at Stanford University, 40 per cent of the Earth's solar energy is directed toward food and fibre production for humans; up to 60 per cent of the world's freshwater resources are currently diverted for agriculture. With the rise of global corporate agribusiness over the past 60 years, the family farm has become a vanishing way of life in the US and elsewhere, and farming is no longer even officially recognized as an occupation by the Census Bureau. As farms that combined row crops and livestock gave way to specialized factory-oriented monocultures at war with pests, diseases and weeds, ever larger machinery necessitated ever larger areas to operate in. Fencerow-to-fencerow conversion of hedgerows, shelterbelts, wetlands and wildways increased the distance between agriculture and the natural world. Mechanical systems engineered to pump deeper and deeper groundwater disrupted basic hydrological functions in most farming regions. Corporate consolidation of farmland led to an ever increasing amount of rented acreage, on which landscape improvements became a low priority. Today, even the small farmer who is conscientious enough to manage farmland responsibly is continually squeezed by the pressure to produce more output for less money. Overgrazing, overplanting, overplowing, chemical-intensive regimens, extensive monocultures and other forms of land misuse are all symptomatic of efforts to make up for low prices by increasing production. Forced to compete in a globally oriented food and fibre system, farmers have often had to forsake goals such as wildlife preservation and long-term landscape conservation (as well as health care and other basic needs) in favour of short-term economic survival.

All the while, the correlation between our shopping lists and the Endangered Species List has been growing at an alarming rate. Farming and ranching activities now involve roughly two-thirds of the US land base in the Lower 48 states and are primary contributors to the imperiling of threatened species and ecosystems. Habitat destruction and fragmentation, the displacement of native species and the introduction of exotic species, pollution of terrestrial and aquatic ecosystems, soil erosion, the persecution of predators, the release of genetically modified organisms and the over-exploitation of non-renewable resources for food production and distribution are among the many ecologically devastating consequences of modern agriculture. In *America's Private Land: A Geography of Hope* published in 1996, for example, the US Department of Agriculture reported that farming activities contributed to 46 per cent of species listed as threatened or endangered, and ranching activities to 26 per cent (USDA, 1999, p54).

Modern agriculture's ecological footprint is drawn into particularly sharp focus by the issue of water development. Nearly two-thirds of the freshwater from lakes, rivers, streams and aquifers supply irrigation to about one-fifth of the agricultural land worldwide (Vickers, 2001). While the scarcity of freshwater is predicted to become the most important factor limiting agricultural production in the future (MacKay, 2001, p53), the technology to use that water remains tragically inefficient. According to the Wild Farm Alliance, US irrigation systems waste 50 per cent of the volume they use (World Resources Institute, 1998–1999). Globally, irrigation systems are only 40 per cent efficient (Wood et al, 2000). While these irrigated lands reap 35–40 per cent of the global harvest (Vickers, 2001), they impart a heavy burden on ecosystems, overdrafting groundwater at rates exponentially greater than the speed of natural replenishment, contaminating riparian systems with sediment and toxic chemicals, causing soil salinization in arid climates and dewatering entire lakes, rivers and freshwater systems. At last count, about 30 per cent of the protected species and the species proposed for protection in the US have been listed due to water resource development (Stein et al, 2000). Roughly a third of freshwater fish species globally are threatened with extinction (Soulé and Piper, 1992). The miraculous salmon runs, for example, that for millennia coursed dramatically through nearly every river system on the West Coast, have been decimated in just 150 years of settlement. The pallid sturgeon is now endangered in inland North American rivers due to lack of spawning sites and is joined by the Yaqui chub, the Topeka shiner and numerous others. Writing in *The Farm as Natural Habitat* (Jackson, 2002), Dr Laura Jackson, reports that '28 per cent of all amphibians, 34 per cent of fishes, 65 per cent of crayfishes, and 73 per cent of freshwater mussels are ranked extinct, imperiled, or rare by the Natural Heritage Network of the Nature Conservancy' (2002, p45). It comes as no surprise then that clashes over water rights between farmers, environmentalists, Indian tribes and urban dwellers have already hit the boiling point, exemplified by conflicts such as in the Klamath Basin in southern Oregon and Northern California and the Skagit Basin in north-western Washington. In September 2002, for example, an estimated 30,000 salmon died on the lower Klamath River, a catastrophic die-off that many people attribute to the diversion of water from the fishery to irrigated farmland. This century is sure to experience only more such escalation.

The dominating role of livestock and feedlot farming on the US agricultural landscape cannot be overestimated. More than 70 per cent of the national farm income is animal based. Of 1.2 billion total acres in agriculture, upward of 600 million acres of private lands (including tribal lands) and at least 250 million acres of public lands are used for grazing. Of the nearly 350 million acres of harvested crops, the majority of the top three crops – corn, soybeans and hay – are largely dedicated to feeding and fattening livestock. And an estimated 13 per cent of the ocean's fish harvests are diverted annually to cattle rations (Platt-McGinn, 1998, p15). Midwestern prairie systems that hold the vast potential to support free-ranging livestock (and native game set amid unbroken grasslands, wetlands, savannas and forests) have been converted into an ocean of corn and soybeans. More than a thousand miles away in the Gulf of Mexico, as a result of industrial corn and soybean production and concentrated animal feedlot operations (CAFOs), excess nutrients draining through the Mississippi River have generated a 8500 square mile dead zone of hypoxia, almost completely depleted of marine life (personal communication from Fred Kirschenmann to the Wild Farm Alliance). Still, much of the 130 million acres of corn and soybeans produced and consumed each year in the US remains largely invisible, as it is heavily processed or fed to animals before it reaches supermarket shelves and tables. For beef cattle, which evolved as grass eaters, the heavy corn diet wreaks havoc on their digestive systems, necessitating increasing use of antibiotics to stave off illness and infections (Pollan, 2002). While growing feed and hay to sustain animals through given periods is age old wisdom, confining as many as 100,000 animals in a CAFO where they never see the light of day, raises ethical questions on existential levels. According to Robert F. Kennedy, Jr., 'North Carolina's hogs currently outnumber its citizens and produce more fecal waste than all the people in California, New York, and Washington combined' (Kennedy, 1999, p66). Cattle production in the arid West is ecologically problematic as well. Though long established across the western landscape, cows, particularly at commercial levels, are largely unsuited for dry and fragile terrain, damaging creekbeds, harming soils, altering habitats and consuming vast quantities of irrigated supplemental hay and feed. While a number of contemporary initiatives to reform ranching impacts on arid lands are genuinely attempting to enhance biodiversity, the long-term ecological compatibility of cattle ranching in many arid regions remains in question.

In spite of this skewed land use system and other urgent ecological challenges, with the proper incentives, assistance and resources, farmers can and should be supported to manage their lands more sustainably, and profitably, while protecting wildland values. A love of the land, a managerial presence in rural and remote areas, years of experience, and a concern for native plants and animals are all common elements among farming communities. Practices such as pasture-based meat production, diversifying land use (growing vegetables, melons, fruits and herbs as well as field crops and animals, particularly for local markets), establishing wildlife corridors along river systems, and protecting critical natural areas on and adjacent to farms and ranches, have already shown great environmental and economic promise. Models and examples of landowners, land trust organizations, government cost-share and incentive programmes, third party ecolabels, wildlife monitoring groups, nonprofits and others working to achieve a compatible balance between farming and ranching activities and the protection of the natural world have emerged throughout the country in the past few decades.

A classic concept with a new vision

Farming with the wild is not a novel concept. 19th- and 20th-century American literature is replete with prophetic philosophical works that attempted to reconcile and redirect a civilization bent on the isolation or elimination of wildness from the broader culture. Henry David Thoreau's *On Walden Pond*, John Muir's *Mountains of California*, Aldo Leopold's *A Sand County Almanac*, Rachel Carson's *Silent Spring* and Wendell Berry's *The Unsettling of America*, spring readily to mind among the hundreds of works of extraordinary vision and insight. Within the sustainable agriculture movement itself, the idea that farms must be managed as natural systems gained considerable currency throughout the 20th century under a variety of names. The organic pioneer Sir Albert Howard insisted upon 'farming in Nature's image' after years of studying traditional agriculture in India. Rudolf Steiner re-envisioned the farm as a 'biodynamic' organism with its own self-sustaining animal-based fertilizers and cyclical patterns of planting, crop rotation and holistic management. US Department of Agriculture programmes of the 1930s were proactive and as concerned about sustainable agriculture as many present-day non-governmental efforts. J. I. Rodale popularized healthful eating and growing of organic foods and his son Robert advanced the practices and theories behind regenerative, organic agriculture. Aldo Leopold was and remains perhaps the country's, if not the world's, most eloquent advocate for the marriage of agriculture and conservation through a new 'land ethic'. Geneticist Wes Jackson's 'perennial polyculture' – an attempt to breed harvestable prairies that would be self-sufficient in fertilizer, weed and pest control – derived its design inspiration from the tallgrass prairie ecosystem. Today a number of terms and their movements describe the move away from monoculture toward polyculture, from an emphasis on annuals to geographically appropriate perennial cropping systems: agroecology, regenerative agriculture, natural systems agriculture, grass farming, succession farming, permaculture, ecoagriculture and farming with the wild.

Since the 1970s, organic farmers have been at the forefront of pioneering research in managing the farm as a natural system, demonstrating that nearly all crops can be grown without chemical inputs and successfully marketed on a variety of scales. Through the establishment of local marketing efforts and massive public education campaigns, the organic movement placed food and fibre production front and centre as a major public issue, and succeeded in linking a farmer and a face with the fruits and vegetables at the nation's tables. With growth rates of 20 per cent per year throughout the 1990s, organics has also become the fastest growing sector of the food industry. Willingly or unwillingly, the organic movement has been assimilated into the national and global economy, and at the turn of the 21st century, a proverbial Berlin Wall has begun to crumble. By 2008, the global organic industry is predicted to reach $80 billion with European Union governments dictating ambitious targets of the amount of arable land they want converted to organic production: Germany, 20 per cent; Belgium, The Netherlands and Wales, 10 per cent each (Baker, 2002). Despite the value of these successes, however, the emphasis of the organic movement has not been on managing farms at the watershed or ecosystem level in ways that complement and enhance the values and services provided by other landscape units such as large, strictly protected and interconnected ecological reserves. Such direct on-farm services of healthy ecosystems include pollination, biological insect and rodent control, nutrient cycling, the regulation of hydrological processes, erosion control, weed suppression and detoxification of chemicals. Instead, the organic agriculture movement has understandably focused its decades-long struggle on important issues less directly linked to biodiversity loss – keeping the family farmer on the land, developing non-toxic production practices and building markets for organic products. Under threat from development, the consolidation of processors and farmland, decreasing farm-gate prices, international competition and corporate domination, survival is at stake. With the mainstreaming of the organic movement, even the futures of small-scale farmers growing for local and niche markets now hang in the balance.

At the same time, spurred by critically plummeting wildlife populations in industrial farming areas, the US Department of Agriculture resumed the allocation of Farm Bill resources for conservation in farm areas in the mid- to late 1980s. What started as a series of pilot programmes (the Conservation Reserve Programme, Wetlands Reserve Programme, Wildlife Habitat Incentive Programme and others) has over nearly two decades resulted in the protection and/or restoration of tens of millions of acres of wetlands, bottomland forests and grasslands nationwide. While spending on conservation programmes remains marginal compared to the subsidies that prop up the mass production of only a handful of commodity crops, thanks to significant pressure from conservationists and environmentalists, as much as $2 billion could be spent on significant programmes in private lands in the coming decade. These efforts will help to expand the amount of wetlands under restoration and protection, fund a broad-scale grasslands conservation programme, target key habitats for imperiled species in agricultural areas and reward farmers for practices such as cover cropping and diversification. There is still much to be learned, however, to make these conservation programmes more ecologically and agriculturally effective.

Adding to this picture of the Lower 48 states, contemporary large-scale wilderness recovery initiatives have set forth a bold and urgent vision for the restoration of functional ecosystems over North America in the 21st century. According to the country's leading conservation biologists, our protected wilderness areas and national parks have become increasingly isolated through surrounding resource extraction and various forms of development. Many are unable to sustain viable populations of the species they harbour, resulting in genetic isolation, inbreeding and ultimately extirpation. As experts including Reed Noss, Michael Soulé and Dave Foreman argue, connecting those fragmented wilderness areas through networks of corridors and mixed-use buffer zones is urgently needed to expand habitat areas for wide-ranging species and to reverse the country's (and the world's) stemming biodiversity crisis.

The dire situation of biodiversity loss and proposals to restore native diversity across broad areas from Alaska to Central America have set the conservation and agricultural communities on a collision course. With such a large percentage of the US landbase in private hands and presently in agriculture – and much of that the most productive lands and habitat, which were settled long before the ethic of conservation took hold – a key to the North American wilderness recovery lies in working with farming and ranching regions. As one example, the Richmond, Vermont-based Wildlands Project, has been drafting strategies and creating maps to recover wilderness on a massive scale throughout North America – with an emphasis on ecosystem processes, the need for recovery of all species and the role of top carnivores to maintain ecosystem integrity. The Wildlands Project has been looking to other organizations, such as the Wild Farm Alliance, for ideas on establishing and maintaining high standards for wildlife-friendly agricultural activities in compatible-use areas.

In their unpublished essay 'Tame and Wild: Organic Agriculture and Wildness', North Dakota wheat farmer Fred Kirschenmann and his co-author David Gould argue for an ever closer merger between conservation biology and agriculture:

> We cannot have healthy 'organic' farms within degraded landscapes. Quite apart from the problem of 'drift' – whether chemical or genetic – there is the fact that the biodiversity necessary to produce the ecosystem services on which our organic farms depend can only be restored and maintained at the ecosystem level. It is the coevolution of a diverse array of species interacting with each other that gives nature its dynamic resilience – something Stuart Kauffman calls 'interacting dancing fitness landscapes' (Gould and Kirschenmann, 2000).

With this evolved thinking, a new vision for a more functionally integrated agriculture is emerging. Such a vision begins with farms that gracefully meld into landscapes supporting a wide – if possible, full – range of native species. Arable lands would be maintained in agriculture but would favour cropping systems that mimic the surrounding landscape, while marginally productive lands would be restored to native habitat. Every farm, while still functioning as its own healthy ecosystem, would in some way act as a corridor connecting it to a larger, ultimately wilder landscape – through clear and free-flowing watersheds, through woodlots and forests, grasslands, hedgerows or wetlands, eventually into roadless areas beyond human intervention. Society would do its part to actively encourage and support community-oriented farmers who grow a mix of crops native to or adapted to their different regions, and who are rewarded for not farming at the expense of native pollinators, carnivores, fish or any other members of wild Nature. Ultimately, entire regions could be recognized or certified by their 'wild' aspects. Such a vision, however, will require new ways of looking at agriculture's place on the landscape. Fortunately, a number of pioneering groups and individuals have already been 'farming with the wild' for a decade or more, and these models can help establish the basis for a nationwide, regionally oriented movement.

Emerging models and wild farm pioneers

Building alliances between historical adversaries will no doubt require tearing down decades-old walls and stereotypes: environmentalists, on the one hand, often lumped with wealthy urbanites and bureaucrats who dispatch regulations from distant power centres, and farmers and ranchers, on the other, frequently perceived as narrow-minded and steeped in a sense of entitlement. What may in fact help to bring both camps together in alliances is a sense of unity in common goals and common foes. Common goals would include maintaining arable farmland within healthy rural communities, keeping rural lands open and free from subdivision and development, restoring native habitat on private and public lands and creating a more natural urban–rural interface. Common foes might include land-exploiting absentee agribusiness corporations, massive concentrated animal feedlot operations and global versus regional food systems. In a recent essay on the subject, the Kentucky farmer and author Wendell Berry wrote:

> I am a conservationist and a farmer, a wilderness advocate and an agrarian. I am in favour of the world's wildness, not only because I like it, but also because I think it is necessary to the world's life and to our own. For the same reason, I want to preserve the natural health and integrity of the world's economic landscapes, which is to say that I want the world's farmers, ranchers and foresters to live in stable, locally adapted, resource-preserving communities, and I want them to thrive. One thing that means is that I have spent my life on two losing sides. As long as I have been conscious, the great causes of agrarianism and conservation, despite local victories, have suffered an accumulation of losses, some of them probably irreparable – while the third side, that of the land-exploiting corporations, has appeared to grow ever-richer. I say 'appeared' because I think their wealth is illusory. (Berry, 2002, p50)

Fortunately, throughout the country, rural communities are launching their own initiatives at the same time they battle the forces of urban development, consolidation in food processing, the globalization of commodity production, rock-bottom farm-gate prices and escalating costs, the flight of an agricultural infrastructure, increasing government regulations and a myriad of other woes. 'These efforts often begin slowly, with farmers and concerned citizens meeting together, talking, sharing, walking fields and grasslands, forming management teams, seeking advice from others', says the Land Stewardship Project's Dana Jackson, who is co-author and co-editor of *The Farm as Natural Habitat*. 'Later they can develop yardsticks to monitor their progress, becoming more conscious of the biological diversity in their regions, increasingly building the knowledge of how natural processes contribute to the farm and to the quality of rural life.'

Our relationship with food was once, and arguably should always remain, one of our deepest connections with the biotic community, for it ultimately determines what kinds of fellow beings we are. At this crossroads early in the 21st century, we face a revolution of no small proportions in how our food and fibre will be produced and at what economic, social and biological costs. Our society will determine, through policies and purchasing habits, through personal and communal commitments, what kinds of landscapes we support and what species remain on them. Farmers cannot be expected to shoulder the brunt of this burden. Without technical and financial assistance in the form of incentives and cost-share programmes, consumer-supported ecolabels and land trust collaborations, farming at the landscape level might remain limited to wealthy landowners and isolated conservation initiatives. Ultimately, success must come through collaboration and the articulation of a new vision for agriculture: consumers who support local producers because they are protecting biodiversity; skilled ecologists who can point the way toward restoration; local resource conservation districts, transportation departments and other programmes that promote and practise restoration in rural areas; financial mechanisms that ensure long-term protection of truly viable wildlife corridors.

The challenge of making agriculture more harmonious with biodiversity, particularly in the face of other social and economic factors, conjures more questions than ready answers. How wild is wild enough? Which species are benefiting and which species are losing from our management decisions? At whose expense should these efforts be made? What is the appropriate balance between agriculture and native biodiversity? Can we make a large-scale shift away from industrial feedlots and toward a more sustainable grass-fed meat economy, including migratory bison populations in appropriate areas and a mosaic of domesticated livestock husbandry in areas where the conditions of local ecosystems and access to markets are suitable? Can a new conservation ethic muster the political, economic and cultural forces necessary to accomplish a vision of farming with the wild? After decades of working in relative isolation, conservationists, farmers and sustainable farming activists are beginning to view agricultural areas as critical terrain in the effort to restore large and healthfully functioning ecosystems throughout the continent. New dialogues, new collaborations, new programmes indicate that such changes are indeed reshaping life down on the farm. We can only hope that time is on the wild's side.

Editorial Introduction to Volume III

Jules Pretty

Food Systems Overview

Recent advances in aggregate farm productivity have only brought limited reductions in the incidence of hunger. At the turn of the 21st century, there were nearly 800 million people hungry and lacking adequate access to food, comprising 18 per cent of all people in developing countries. A third were in East and South-East Asia, another third in South Asia, a quarter in sub-Saharan Africa, and a twentieth each in Latin America and the Caribbean, and in North Africa and the Near East. Nonetheless, there had been progress to celebrate, as the incidence of undernourishment stood at 960 million in 1970, comprising a third of people in developing countries at the time. Since then, average per capita consumption of food increased by 17 per cent to 2760 kilocalories per day – good as an average, but still hiding a great many people surviving on less: 33 countries, mostly in sub-Saharan Africa still have per capita food consumption under 2200 kcal per day. The challenge remains huge.

There is also significant food poverty in industrialized countries. In the US, the largest producer and exporter of food in the world, 11 million people are food insecure and hungry and a further 23 million are hovering close to the edge of hunger – their food supply is uncertain but they are not permanently hungry. Of these, 4 million children are hungry and another 10 million are hungry for at least one month each year. Despite this progress in food output, it is likely that food-related ill health will remain widespread for many people. As world population continues to increase, until at least the mid 21st century, so the absolute demand for food will also increase. Increasing incomes will also mean people will have more purchasing power, and this will increase demand for food. But as diets change, so demand for the types of food will also shift radically, with large numbers of people going through the nutrition transition, as first described by Barry Popkin (*The Nutrition Transition: Diet and Diseases in the Developing World*, 2002; Academic Press). In particular, increasing urbanization means people are more likely to adopt new diets, particularly consuming more meat, fats and refined cereals, and fewer traditional cereals, vegetables and fruit.

As a result of these transitions towards calorie-rich diets, obesity, hypertension and type II diabetes have emerged as serious threats to health in most industrialized countries. A total of 20–25 per cent of adults across Europe and North America are now classed as clinically obese (with a body mass index > $30kg/m^{-2}$). In some developing countries, including Brazil, Chile, Colombia, Costa Rica, Cuba, Ghana, Mexico, Peru and Tunisia, overweight people now outnumber the hungry. Diet-related illness now has severe and costly public health consequences. According to the comprehensive Eurodiet study published in 2001 (http://eurodiet.med.voc.gr/first.html), 'disabilities associated with high intakes of saturated fat and inadequate intakes of vegetable and fruit, together with a sedentary lifestyle, exceed the cost of tobacco use'. Some problems do arise from nutritional deficiencies of iron, iodide, folic acid, vitamin D and omega-3 polyunsaturated fatty acids, but most are due to excess consumption of energy and fat (causing obesity), sodium as salt (high blood pressure), saturated and trans fats (heart disease) and refined sugars (diabetes and dental caries).

An important driver of change in the world food system will arise from increased consumption of livestock products. Meat demand is expected to rise rapidly with economic growth, and this will change many farming systems. Livestock are important in mixed production systems, using foods and by-products that would not have been consumed by humans. But increasingly animals are raised intensively, and fed with cheap though energetically inefficient cereals and oils. In industrialized countries, 73 per cent of cereals are fed to animals; in developing countries, some 37 per cent are used in this way. Currently, per capita annual demand in industrialized countries is 550kg of cereal and 78kg of meat. By contrast, in developing countries it is only 260kg of cereal and 30kg of meat.

At the same time as these changes, farmers in many parts of the world are finding it increasingly hard to make a living. One reason why they struggle is that the proportion of the food pound or dollar returning to farmers has shrunk. Fifty years ago, farmers in Europe and North America received as income between 45–60 per cent of the money consumers spent on food. Today, that proportion has dropped to just 7 per cent in the UK and 3–4 per cent in the US, though it remains at 18 per cent in France. So even though the global food sector continues to expand, now standing at $1.5 trillion a year, farmers are receiving a relatively smaller share. In recent decades, the value of food has been increasingly captured by manufacturers, processors and retailers. Farmers simply sell basic commodities, and others add the value. As a result, less money gets back to rural communities and cultures, and they in turn suffer economic decline. But if farmers are receiving such a small proportion of the food pound and dollar, what happens when they sell direct to consumers? Do their farms and landscapes change for the better?

The basic challenge for a more sustainable agriculture is to make best use of available natural and social resources. Farming does not have to produce its food by damaging or destroying the environment. Farms can be productive and farmers earn a decent living whilst protecting the landscape and its natural resources for future generations. Farming does not have to be dislocated from local rural cultures, as sustainable agriculture, with its need for increased knowledge, management skills and labour, offers new upstream and downstream job opportunities for businesses and people in rural areas. This suggests a logical need to emphasize agriculture's connections to local ecologies and communities.

When food is a commodity, there is little to stop over-consumption. There are no checks and balances to have us worry about the hidden costs of certain types of food production. Our current food system, despite considerable performance improvements in recent decades – it is faster, fitter and more streamlined – is still flawed. However, collective action by producers of food, by consumers and by novel mixtures of both groups can make a difference. It is possible to create new forms of relationship, trust and understanding, leading to new cognitive constructions of food and its cultures of production.

Two concepts are useful in this rethinking – the ideas of bioregions and foodsheds. Bioregionalism implies the integration of human activities within ecological limits, and bioregions are seen as diverse areas with many ecological functions. Bioregionalism can thus be seen as a self-organizing or autopoiētic concept, which connects social and natural systems at a place people can call home. Bioregions are real places where people want to live. They can take years to build, emerging from the interactions of people who are not indifferent to the outcomes. People leave their mark and in turn are shaped by local circumstances and cultures. The term foodshed has been coined to give an area-based grounding to the production, movement and consumption of food. Foodsheds have been described by Jack Kloppenberg as 'self-reliant, locally or regionally based food systems comprised of diversified farms using sustainable practices to supply fresher, more nutritious food stuffs to small-scale processors and consumers to whom producers are linked by the bonds of community as well as economy'.

The basic aim of regionalized foodsheds is twofold. They shorten the chain from production to consumption, so eliminating some of the negative transport externalities and helping to build trust between producers and consumers, and ensuring more of the food pound gets back to farmers. They also tend to favour the production of positive environmental, social and health externalities over negative ones through the use of sustainable production systems, leading to the accumulation of renewable assets throughout the food system.

Part 1: The Global Food System

The pursuit of increased productivity and conserved natural resources in the course of rural modernization has produced benefits in the form of improved food production and some improvements in resource conservation. The increases in food production have been significant. These improvements look so good that it is easy to be tempted to forget questions such as: 'What is the cost of this improvement?' 'Who benefits and who loses out?' Many would argue that the ends justify any reasonable means. Yet it is increasingly being recognized that the social and environmental costs of agricultural modernization cut deep into the fabric of society. Modernization in the urban environment has been characterized by alienation and conflict, increased individualism and a breakdown of communities. Much the same is true in rural environments. Jobs have been lost, environments polluted, communities broken up and people's health harmed.

All sectors of economies are affected. The drive for agricultural efficiency has drastically cut the numbers of people engaged in agriculture in industrialized countries. External inputs of machines, fossil fuels, pesticides and fertilizers have displaced workers in Green Revolution lands. Rural cultures have been put under pressure, as more people have been forced to migrate in search of work. Some local institutions, once strong, have become co-opted by the state or have simply withered away. Farms have become simplified and some resources, once valued on the farm, have become wastes to be disposed off the farm. Some external inputs are lost to the environment, so contaminating water, soil and the atmosphere. Agriculture has become more fossil-fuel intensive, so contributing to global warming. Overuse or continued use of some pesticides causes pest resistance and leads to pest resurgences, encouraging farmers to apply yet more pesticides. The first article by Jules Pretty reviews these thematic challenges, as well as analysing in detail case studies on pesticides in the Philippines, soil erosion in the US, Africa and India, social change in Britain, Japan and the US, modernism in Mexico, social change in rice cultivation areas of Indonesia, and conflicts between pastorialists and wheat farms in Tanzania.

The real agricultural challenges of the future will, as today, differ according to their geopolitical and socioeconomic contexts. The current divide between those who eat well and those who go hungry will continue, defined largely by differences in per capita incomes within and between countries. Factors that distinguish the various trajectories of agricultural development also exhibit significant spatial variability, such as differences in farming systems and productive capacity, population densities and growth, evolving food demands, infrastructure and market access, as well as the capacity of countries to import food or to invest in agricultural and environmental improvement. Environmental problems associated with agriculture also vary according to their spatial context, ranging from problems associated with the management of modern inputs in intensively farmed areas to problems of deforestation and land degradation in many poor and heavily populated regions with low agricultural potential.

In the second paper Robert Tripp summarizes the findings of a study that examined the performance of low external input technology in three major projects. The projects promoted soil restoration (Honduras), soil and water conservation (Kenya) and Integrated Pest Management (IPM, Sri Lanka). The focus projects were large and well managed and the study examined outcomes five or more years after project completion. An assessment of the utilization, adaptation and abandonment of the technologies found fairly consistent experiences that allow several general conclusions. In many instances, these methods make important contributions to farm productivity. Low external input technology is often labour-intensive and the growing importance of hired labour makes it difficult to see it always succeed. Its uptake patterns are similar to those of conventional technology (with commercial incentives particularly important). On its own, according to this study, it makes only modest contributions to strengthening human and social capital. Implications for the promotion and development of farmer organizations are discussed.

In the third article, the opener to the book *The Politics of Food*, Marianne Lien sets out how food has emerged as a political topic. Recent food scandals, such as the outbreak of bovine spongiform encephalopathy (BSE) and the public debate over genetically modified foods, have exposed many dilemmas in modern food production and consumption. This paper seeks to draw attention to some of the less obvious ways in which food is politicized. 'What's for dinner?' is no longer a simple question. Food is not only a commodity for consumption, but is politicized all the way into the kitchen and to the dinner table, with many implications for cooking and family care. Food is argued over in transnational fora, seen in different ways by experts ranging from nutritionists to anthropologists and regulated by governments the world over. Trust in food is culturally established and varies geographically (some eat dogs, others eat snails; many eat neither). At the same time, food is a connection to the natural environment, which may or may not have been affected positively by the types of production systems in use.

The fourth paper by Abha Mishra et al addresses the remarkable appearance of a new system of rice cultivation in recent years. Increasing demand for cereals produced from limited natural resources stimulated the Green Revolution in grain crops such as wheat and rice. But the gap between potential and actual production continues. Concerns about sustainability, and the social and technical shortcomings of the Green Revolution, have triggered a number of alternative crop production strategies. One, in particular, the so-called System of Rice Intensification (SRI), is attracting attention by governments and farmers in Asia and elsewhere. The suite of cultural practices that characterize SRI, including rapid and shallow transplanting of younger seedlings, more widely spaced and with reduced irrigation water, are all amenable to farmer experimentation and adaptation to suit local conditions. Thus, SRI encourages farmer participation in devising practical ways of growing a healthy crop in a sustainable manner. SRI develops a dynamic relationship between farmers, trainers and researchers, defining a clearer and distinct role for each in knowledge creation and innovation.

The science behind SRI is equally challenging, especially in relation to processes below ground level that affect soil ecology and root development. This paper reviews the evidence for each element of SRI. The relevant literature is extensive but has not been linked with the development of SRI, which was largely inductive, not guided by prior research. An integrated model is proposed that links root activity to grain yield. This model maintains the accepted paradigm that there is a significant relationship between a plant's cytokinin content and its response to the environment. This study makes clear that optimizing the plant/environment interaction for better yield through integration of biophysical issues is a challenging task given the diversity and location-specificity of production environments. This challenge is best met by actively engaging rice farmers and trainers, from the outset, in improving the production process.

In the final paper of this section, Thomas Dietz, Elinor Ostrom and Paul Stern provide a 2003 update on the Hardin thesis in a paper entitled *The Struggle to Govern the Commons*. As they indicate, Hardin's oversimplification in this tragedy of the commons was twofold: he claimed that only the state could establish institutional arrangements that could sustain the commons in the long-run, and presumed that resource users were trapped in a commons dilemma, and so therefore unable to create new solutions. The authors indicate that there is, of course, an enormous threat to ecosystems from inadequate governance, and state that 'developing effective governance systems is akin to a co-evolutionary race … successful commons governance requires that rules evolve'. Effective commons governance is easier to achieve when the resources can be monitored, when the rates of change in resources and technologies are moderate, when communities maintain frequent face-to-face communication, when outsiders can be excluded at relatively low cost and when users support effective monitoring and rule enforcement. The authors then set out the requirements for adaptive governance in complex systems, and these centre on (i) providing information, (ii) dealing with conflict, (iii) inducing rule compliance, (iv) providing infrastructure, (v) being prepared for change, (vi) ensuring analytical deliberation, (vii) nesting of institutional arrangements, and (viii) institutional variety. The paper shows that as the footprint of humanity on the earth enlarges, so 'humanity is challenged to develop and deploy understanding of broad-scale commons governance quickly enough to avoid the broad-scale tragedies that will otherwise ensue'.

Part 2: Poverty and Hunger

Robert Chambers is one of the world's foremost writers and innovative practitioners on approaches to agricultural development that build first on the knowledge and skills of the poorest. Their continuing exclusion from the economic and social benefits of rural development remains a scandal. In his 2005 book, *Ideas for Development* (Earthscan) Chambers draws together his experiences over four decades to indicate how we need to think differently as well as act differently if any lasting and significant contribution to poverty reduction is to be made. In this opening chapter, he reflects on settlement schemes in tropical Africa from the late 1960s and early 1970s. Here the emphasis is on our need to learn from experience. The second part of the chapter reviews subsequent developments with settlement schemes and then explores wider contemporary meanings, relevance and applications for these three key words: commitment, continuity and irreversibility. Throughout, the effects of biases and neglect in recent patterns of agricultural development are exposed and lessons suggested for the future.

One of the problems with trying to identify both priorities and action in agricultural development centres on our understanding of what 'improvement' means.

Agricultural development seeks to improve peoples' lives, or crop yields, or water quality or food supply. Yet it is a comprehension of what constitutes well-being and ill-being that should be the starting point. Both are states of mind and being. Well-being has a psychological and spiritual dimension as a mental state of harmony, happiness and peace of mind. Ill-being includes mental distress, breakdown, depression and madness – often described by people as the impacts of poverty. This article by Deepa Narayan and colleagues forms the second chapter in the World Bank sponsored study *Voices of the Poor*, in which perspectives of poverty are drawn from a wide range of countries. Despite the diversity of poor participants in the study, their ideas of well-being and what constitutes the good life were both multidimensional and had much in common. Interestingly, enough for a good life is not necessarily a lot, and for those with little, a little more can mean a great deal. Wealth and well-being are seen as different, and often contradictory. Descriptions of ill-being are also multidimensional and interwoven – yet how little do these perspectives appear in externally driven efforts to improve people's lives.

Lester Brown's 2002 book, *Who Will Feed China*, drew attention to the rapid economic development and accompanying consumption patterns within China, and how these could impact both local and international agricultural and food systems. We know that already many of the world's population now aspire to a US standard of living, and yet adoption of such lifestyles will be impossible. Increased population, for the first half of this century at least, combined with increased consumption, will, as Brown puts it, 'eventually collide with the earth's natural limits'. The first two chapters of this book provide an overview to these challenges, and the second focuses on population increase and associated policies. The latter is a Malthusian perspective – unless population growth is limited and stopped, the world's natural resource base will be more and more threatened. It is, though, population × consumption that is the key driver, and what is quite clear from Brown's analysis is that if so-called developing countries adopt the same consumption patterns as those already in industrialized countries, then ecological limits will soon be reached and breached. Alternative patterns of development and new aspirations will be essential.

Some of these alternatives will centre on the need to intensify agriculture (by producing more from the same lands), address rural poverty and protect or enhance biodiversity. In the opening sections to their book, *Ecoagriculture*, Jeff McNeely and Sara Scherr set out the challenge: a mutually supportive relationship between agriculture and the natural world needs to be developed. As Norman Myers has said, 'sensible use of nature … is essential to feed the planet… Nature equals food. Without wild places, we cannot hope to have food on our tables.' In this book, the management of landscapes for both the production of food and the conservation of ecosystem services, in particular wild biodiversity, is what the authors called ecoagriculture. Of course, this is easy to say but difficult to do. A wide range of genetic, technological, environmental management and policy innovations must be developed to support wild biodiversity in the world's bread baskets and rice bowls, as well as in the extensive areas where food production is more difficult.

And diverse approaches are indeed being developed and extended across many different environments and societies, both in developing and industrialized countries. The next challenge is to get some of these opportunities reflected in national and international policies.

What is the best way to increase agricultural productivity in developing countries that still, despite efforts over several decades, have some 800 million people short of food? The question is controversial, with widely varying positions about the types of inputs and technologies likely to be effective. Great technological progress in the past half century has not been reflected in major reductions in hunger and poverty in developing countries. However, many novel initiatives have emerged that are demonstrating that agriculture in poor countries can be greatly improved. In this fifth paper, Jules Pretty and colleagues evaluate how farmers in 286 projects in 57 countries had improved food crop productivity since the early to mid-1990s, and at the same time increased both water use efficiency and carbon sequestration and reduced pesticide use. These initiatives also offer the prospects of resource-conserving agriculture both reducing adverse effects on the environment and contributing to climate change mitigation. These 286 recent interventions in 57 poor countries covering 37Mha (3 per cent of the cultivated area in developing countries) had increased productivity on 12.6 million farms whilst improving the supply of critical environmental services. The average crop yield increase was 79 per cent (geometric mean 64 per cent). All crops showed water use efficiency gains, with the highest in rainfed crops. Potential carbon sequestered amounted to an average of 0.35t C ha^{-1} y^{-1}. Of projects with pesticide use data, 77 per cent resulted in a decline in pesticide use by 71 per cent whilst yields grew by 42 per cent. Whilst it is uncertain whether these approaches can meet future food needs, there are grounds for cautious optimism, particularly as poor farm households benefit more from their adoption.

Part 3: Diet and Health

Eve Balfour's classic 1940s book, *The Living Soil*, is seen by many as a key text in the establishment of the organic movement. She was both a farmer and a thinker, and contributed substantially to the national understanding of the connections between farming systems, and the soil on which they are based, and the effects of food on health. She asks, 'what shall I eat that I may be whole?' The types of foods and the balance between them fundamentally affects our health, and yet for many decades in the latter part of the 20th century this seems to have been forgotten. In this chapter, Balfour draws on a variety of cultures to illustrate how important diets are to health. The first is the people of the Hunza, now part of the northern areas of Pakistan. They were healthy people at the time, with all their foods locally derived. Today, they are more connected to external markets, but still rely on a variety of healthy foods. Other examples in the chapter draw on analysis of Faroe

Islanders and Iceland, native Eskimos (as they were then known), and the people of rural China (using F. H. King's book).

Barry Popkin of the University of North Carolina made a significant contribution to our understanding of changing diets by coining the phrase 'the nutrition transition'. Human history is, of course, characterized by many changes in diets and nutritional status, but the pace of change has considerably quickened in recent decades. The most recent nutrition transition has created an age of degenerative diseases and conditions that are avoidable, but only if there are rapid changes in both diet and levels of physical activity. Popkin sets out five periods in human populations: the age of collecting food, the age of famine, the age of receding famine, the age of degenerative diseases and the age of behavioural change. The last is yet to occur in industrialized countries. Across all industrialized countries, and increasingly in wealthier populations in developing countries, people have adopted diets containing 'superior grains' (rice or wheat instead of maize or millet), more milled and polished grains, food higher in fats, more animal products, more sugar and more food either prepared away from the home or processed.

The third article is drawn from Tim Lang and Michael Heasman's book *Food Wars*, and focuses on diet and health, and what has occurred during the recent experiment with modern agricultural systems that has focused primarily on increasing food production without concern for what has been lost. Modern agriculture has produced a commodity-based food system, and the diets of the majority of people in industrialized countries have shifted enormously. Food-related ill health now exceeds the costs of smoking in Europe and North America, with obesity, type II diabetes, cardiovascular diseases, diet-related cancers and osteoporosis on the increase. There are now some 1.7 billion people worldwide who are overweight – in a world where 800 million people remain hungry on a daily basis. Lang and Heasman set out details of this nutrition transition, and indicate precisely how diet composition has changed. We are now in a world where there are large numbers of underfed, overfed and badly fed, and this of course raises significant questions for policy makers who are largely yet to grasp the need for fundamental change.

Marion Nestle's book, *Food Politics*, is subtitled 'how the food industry influences nutrition and health', and this opening chapter indicates the extent to which diets and food choices are cleverly shaped by corporate interests, and how these of course affect people's health. The food industry has given many people in the world a plentiful food supply that is both varied and inexpensive, as well as devoid of dependence on geography and season. In the US, food supply is so abundant that it contains enough food to feed everyone in the country nearly twice over. To satisfy shareholders, food companies must convince people to eat more of their own products instead of those of competitors, and this requires considerable investment in advertising and public relations that is not only targeted at consumers, but at government officials, nutrition professionals and the media. Nestle shows how food companies use political processes (entirely conventional and nearly always legal) to obtain the support they need for the sale of their products. This opening chapter reviews what constitutes a healthy diet, shows why diet does matter and analyses whether Americans overeat. A review of the structures and actors in the US food industry then follows, including how marketing imperatives drive taste, cost, convenience and confusion. Through all this is the corporate need to promote eating more, especially amongst children, who then get the habit for life.

Eric Schlosser's book *Fast Food Nation* deservedly received great public attention. It has a clear and simple message, and documents just how fast food has come to dominate diet and life in the US. It could be said to be simplistic, in identifying corporate institutions as the main protagonists of dietary change. On the other hand, the obesity crisis emerged quietly at the end of the 20th century, with only 6 per cent of adults obese in the early 1980s, and 25 years later it affects more than 25 per cent. In this chapter, Schlosser explores the wide range of approaches taken by a single restaurant corporation, McDonalds. It is modernism at its most effective – a common language and culture spread across all employees, all restaurants, in all countries where they operate. The focus on children as customers (not the parents) is clearly exposed – advertising is directed to children, who use their 'leverage' or 'pester power' to affect the behaviour and choices of adults. Fast food companies spend $3 billion annually on television advertising in the US. In the late 1970s, a teenager drank 7oz of soda daily; today it is three times as much. This is liquid candy or empty calories, serving just to increase the incidence of obesity.

Part 4: Localized Food Systems

In the first article, Jack Kloppenburg and co-authors set out the compelling concept of the foodshed, and indicate just how connections to food and place can make a difference for both consumers and producers. As they say, 'if we are to become native to our places, the foodshed is one way of envisioning that beloved country'. They, too, though, show that fundamental changes are required if we are to evolve more ecologically and socially responsible agricultural and food systems. This raises questions about the nature of economies as a whole – are they simply geared in such a way so as to prevent sensible outcomes for people and nature? Or can they be changed too? The idea of the foodshed, a socio-geographic space, in which human activity is embedded in the natural integument of the particular place, is powerful and could help to provoke some serious rethinking about whole agricultural systems and their sustainability.

There are many perspectives on what constitutes sustainability and how it can be applied equally across agricultural contexts. As a result, a variety of analytical approaches have been developed, including energy accounting, economic valuation of non-marketed goods and services, ecological footprints, carbon accounting and the use of indicators for sustainability. Most of these approaches have only focused on environmental impacts up to the farm gate, and have not assessed the additional environmental effects of transporting foodstuffs via processing to retail outlets and then to the point of consumption. Evidence is mounting that these farm to plate transport costs, or 'food miles', are substantial. In addition, there is growing interest in local and regionalized food supply systems and the potential social and environmental benefits they could bring. This study by Jules Pretty, Tim Lang and colleagues analyses the full costs of foods in the average weekly UK food basket by calculating the costs arising at different stages from farms to consumers' plates. Of the 12 commodities assessed, livestock produce contributes the most costs per kg. Agricultural and food produce accounts for 28 per cent of goods transported on UK roads, currently imposing estimated external costs of £2.35bn yr^{-1}. The contribution made by sea and air transport is currently trivial owing to low volumes. However, road transport to carry food from the shop to home is estimated to impose a further £1.28bn yr^{-1} to total external costs. The paper assesses a variety of scenarios for the adoption of organic farming, localized food systems and sustainable transport to indicate the substantial potential to reduce environmental costs in the UK food system.

Facing a major agricultural crisis, European countries are searching for alternatives to the intensive-production agricultural development model promoted since the early 1950s. Agenda 2000 introduced significant changes in the Common Agricultural Policy (CAP) by recognizing the multifunctionality of agriculture and by giving more importance to the second pillar, a term used for the measures supporting wider rural development. Meanwhile, agri-environmental schemes are taking on much greater importance in the overall policy mix for agriculture in European Union (EU) countries. With respect to the idea of multifunctional agriculture, one way to raise farmers' environmental stewardship is to reward environmental practices through food quality labelling schemes. The objective of this study by Genevieve Nguyen and colleagues was to identify existing relationships between the production of quality food and the production of environmental goods at the farm level. In this paper, we report the results of analyses conducted to examine the effects of major 'quality' and 'ecolabelling' schemes in the Midi-Pyrenees regions of the south of France. Factor analysis and analysis of variance were used with a data set of 107 farms – some participating in the labelling schemes and some not participating – for which environmental scores had been assigned. The statistical analyses were complemented by a qualitative analysis based on in-depth interviews of 85 farmers and review of the labelling standard guidelines. This study shows that organic farms and farms enrolled in various quality and eco-labelling programmes in France do provide some environmental benefits. However, they do not necessarily perform better than other farms on all environmental measures.

At the turn of the century, Cuba was of the few developing countries in the world with an explicit national policy for sustainable agriculture. To the end of the 1980s, Cuba's agricultural sector was heavily subsidized by the soviet bloc. It imported more than half of all calories consumed, and 80–95 per cent of wheat, beans, fertilizer, pesticides and animal feed. It received three times the world price for its sugar. But in 1990, trade with the soviet bloc collapsed, leading to severe shortages of all inputs. The government's response was to declare an 'Alternative

Model' as the official policy – an agriculture that focuses on technologies that substitute local knowledge, skills and resources for the imported inputs. Two important strands to sustainable agriculture in Cuba have emerged. First intensive organic gardens have been developed in urban areas – self-provisioning gardens in schools and workplaces (*autoconsumos*), raised container-bed gardens (*organoponicos*) and intensive community gardens (*huertos intensivos*). There are now more than 7000 urban gardens, and productivity has grown from 1.5kg per square metre to nearly 20kg per square metre. Second, sustainable agriculture is encouraged in rural areas, where the impact of the new policy has already been remarkable. This paper by Nelso Companioni and colleagues is from Fernando Funes' book *Sustainable Agriculture and Resistance*, which documents in detail these agricultural changes in Cuba. This chapter focuses on the urban agriculture component, and shows how small areas of urban land have made such significant contributions to national food security. Urban agriculture is important to families in many countries, yet it is often forgotten by policy makers.

In the final article in this volume, Terry Marsden explores the quest for ecological modernization in industrialized food systems. He focuses on challenging the prevailing economic notions of scale, critical mass and centralization, and suggests that ecological modernization raises a new question: 'how could/should the contested relationships between civil society, the state and the market be rearranged in ways which would usher in different types of autonomous development which would incorporate ecological worth?' Through three areas, agriculture, restructuring food supply chains and forestry, Marsden explores how ecologically modernizing processes are operating in industrialized societies, and how these in turn are influencing rural development trends. As ecology has emerged as an important objective, so it has become embedded more into the institutions of economy. Might this lead just to a stronger growth treadmill, or a different and possibly more robust rural development paradigm? What does this mean for specific sectors? In South Wales, for example, forestry authority attempts to encourage more participation and inclusion in forested areas is constrained by deprivation in local communities, where other state services are being withdrawn. Food deserts in large cities are enclaves hidden from most who see corporate-led retail outlets as being abundant and cheap, rather than missing. Monopolistic retail arrangements affect the marginalized in society the most. And common to many places, primary producers who are, of course, nearest to the land, are being gradually discouraged as regulators seek to protect consumers, and corporations themselves acquire most of the value in the food chain.

Part I

The Global Food System

1

The Environmental and Social Costs of Improvement

Jules Pretty

But when the motor of a tractor stops, it is as dead as the one it came from. The heat goes out of it like the living heat that leaves a corpse. Then the corrugated iron doors are closed and the tractor man drives home to town, perhaps twenty miles away, and he need not come back for weeks or months, for the tractor is dead. And this is easy and efficient. So easy that the wonder goes out of the work, so efficient that the wonder goes out of the land and the working of it, and with the wonder the deep understanding and the relation.

John Steinbeck, *The Grapes of Wrath*, 1939

The General Costs of Improvement

The pursuit of increased productivity and conserved natural resources in the course of rural modernization has produced benefits in the form of improved food production and some improvements in resource conservation. The increases in food production have been significant. Despite the world population more than doubling in the past 50 years to some 5.6 billion, food production per capita has been able to keep pace. Over the same period, the amount of land conserved or protected has also increased. In the tropics alone, the land devoted to national parks and protected areas has grown from 58 to 174 million ha.

These improvements look so good that it is easy to be tempted to forget: 'What is the cost of this improvement?' 'Who benefits and who loses out?' Many would argue that the ends surely justify any reasonable means. Yet it is increasingly being recognized that the social and environmental costs of agricultural modernization cut deep into the fabric of society. Modernization in the urban environment has been characterized by alienation and conflict, increased individualism and a breakdown of

communities. Much the same is true in rural environments. Jobs have been lost, environments polluted, communities broken up and people's health damaged.

All sectors of economies are affected. The drive for agricultural efficiency has drastically cut the numbers of people engaged in agriculture in industrialized countries. External inputs of machines, fossil fuels, pesticides and fertilizers have displaced workers in Green Revolution lands. Rural cultures have been put under pressure, as more and more people have been forced to migrate in search of work. Local institutions, once strong, have become co-opted by the state or have simply withered away. Farms have become simplified and some resources, once valued on the farm, have become wastes to be disposed off the farm. Some external inputs are lost to the environment, so contaminating water, soil and the atmosphere. Agriculture has become more fossil-fuel intensive, so contributing to global warming. Overuse or continued use of some pesticides causes pest resistance and leads to pest resurgences, encouraging farmers to apply yet more pesticides.

Environmental pollution and contamination by agriculture

The agricultural production increases brought about by high input packages have brought great benefits. Without them many people would be worse off than they are now; many others might have died of starvation. But in order to assess the true net benefits of high input packages, it is important also to understand some of the external costs.

The environmental problems caused by farming are a direct result of an increasingly intensive and specialized agriculture. The mixed farm can be an almost closed system, generating few external impacts. Crop residues are fed to livestock or incorporated in the soil; manure is returned to the land in amounts that can be absorbed and utilized; legumes fix nitrogen; trees and hedges bind the soil, and provide valuable fodder, fuelwood and habitats for predators of pests. In this way the components of the farm are complementary in their functions. There is little distinction between products and by-products. Both flow from one component to another, only passing off the farm when the household decides they should be marketed.

Over the last half century, many such highly integrated systems have disappeared. Farms have become more specialized with crop and livestock enterprises separated. Intensification of agriculture has meant greater use of inputs of pesticides, fertilizers and water, and a tendency to specialize operations. The inputs, though, are never used entirely efficiently by the receiving crops or livestock and, as a result, some are lost to the environment. Some 30–80 per cent of applied nitrogen and significant but smaller amounts of applied pesticides are lost to the environment to contaminate water, food and fodder and the atmosphere (Conway and Pretty, 1991). Water is often wasted or used inefficiently, leading to groundwater depletion, waterlogging and salinity problems. This is not only wasteful, but costly to those who want to use these resources and expect them to be uncontaminated.

Many environmental and health impacts have increased in recent years; others have continued to persist despite all efforts to reduce them (Conway and Pretty, 1991). Water systems have become increasingly contaminated. Nitrate in water can give rise to the condition methaemoglobinaemia in infants and is a possible cause of cancers. Pesticides contaminating water can harm wildlife and exceed drinking water standards. Nitrates and phosphates from fertilizers, and organic wastes from livestock manures and silage effluents all contribute to algal growth in surface waters, deoxygenation, fish and coral deaths, and general nuisance to leisure users. Eroded soil also disrupts watercourses, and run-off from eroded land causes flooding and damage to housing, irrigation systems and natural resources.

Various pollutants also harm farm and local natural resources. Pesticides damage predator populations and other wildlife and induce resistance in target pests. Nitrates from fertilizers and ammonia from livestock waste disrupt nutrient-poor wild plant communities. Metals from livestock wastes raise metal content of soils, and pathogens in wastes can harm human and livestock health. The atmosphere is contaminated by ammonia, which plays a role in acid rain production; nitrous oxide derived from fertilizers, which plays a role in ozone layer depletion and global warming; and methane from livestock and paddy fields, which also affects global warming.

The consumer is most likely to be directly affected by eating food contaminated mainly by residues of pesticides, but also by nitrates and antibiotics. In the industrialized countries, the levels of pesticides in foods have been falling steadily since the 1950s (Conway and Pretty, 1991; WPPR, 1994; Gartrell et al, 1986a, 1986b). Nonetheless, there are occasional public scares over particular products and rare incidents of severe poisoning arising from the spraying of illegal products. But in developing world countries, daily intakes are often very high. These may be in cereals, such as in India (Kaphalia et al, 1985; Sowbaghya et al, 1983); in fish, such as from rice fields in Malaysia (Chen et al, 1987) or lakes and rivers of Kenya, Nigeria and Tanzania (Atuma, 1985; Atuma and Okor, 1985); and in milk from cows affected by spray drift from cotton plantations in Nicaragua and Guatemala (ICAITI, 1977).

But the major hazard lies in locally marketed food. Leafy vegetables are often sprayed twice a week and may come to market with a high degree of contamination, especially in the dry season. Over 50 per cent of green leafy vegetables collected around Calcutta during the dry winter months contained residues, though this fell to 8 per cent in the wet season (Mukherjee et al, 1980). In Indonesia, cabbages and mustard greens have been found to contain organophosphates many times in excess of human tolerance limits (Darma, 1984). Similar levels of contamination have been recorded from Africa (Atuma, 1985).

These costs of environmental damage are growing, and are dispersed throughout many environments and sectors of national economies. For a comprehensive review of the effects of agricultural pollution on natural resources, wildlife and human health see Conway and Pretty (1991). What has characterized recent analyses has been the recognition that farmers themselves are suffering declining incomes or health effects from these modern approaches to agriculture. The following sections consider the issues of energy consumption by agriculture, pest resistance and resurgences, health impacts of pesticides and soil erosion.

Energy consumption by agriculture

A largely hidden cost of modern agriculture is the fossil fuel it must consume to keep outputs high. Modern agriculture has tended to substitute external energy sources for locally available ones. With the increasing use of nitrogen fertilizers, pumped irrigation and mechanical power, which are all particularly energy intensive, agriculture has become progressively less energy efficient. These three account for more than 90 per cent of the total direct and indirect energy inputs to farming in developing world countries (Leach, 1985, 1976). Mechanization reduces the labour required for agriculture and so can cut variable costs if energy is cheap, as it is in most industrialized countries. But for poorer countries, mechanization forces increased foreign exchange expenditure on fuel, oil, engines and spares.

There have been many approaches to energy accounting for agricultural systems (Leach, 1976, 1985; Stout, 1979; Stanhill, 1979; Pimentel, 1980; Smil et al, 1982; Dovring, 1985; Pimentel et al, 1989; OECD/IEA, 1992; OECD, 1993). These use such a variety of conventions that it is difficult to make direct comparisons. Some include only the direct fossil fuel energy consumed on farms; others seek comprehensive energy balances by including all the indirect energy consumed in manufacturing equipment and inputs, transporting produce to and from farms, and the energy required to feed human and animal labour on the farm. Direct energy represents what is immediately vulnerable to supply interruptions and so is of more immediate interest to farmers. In general, apart from nitrogen fertilizers, the manufacture of which is extremely energy intensive, direct energy costs far exceed indirect costs (Leach, 1985).

With the greater use of machinery, fuel and nitrogen fertilizers in modern high input agriculture, energy consumption is substantially greater than equivalent low input or organic systems (Table 1.1). In the Philippines, for example, a doubling of yields comes at the cost of an 8- to 30-fold increase in energy consumption. In India, a 10–20 per cent increase in yields following mechanization costs an extra 43–260 per cent in energy consumption. And in the US, high input systems can consume 20–120 per cent more energy than low input systems, even though yields may be comparable. Larger farms also tend to use relatively more energy than smaller ones. In the Punjab, farms in a class 14–25ha use three times as much direct energy per hectare as farms smaller than 6ha (Singh and Miglani, 1976).

Comparisons within countries or even regions are much more likely to be reliable than those between countries, as so many confounding factors become important. However, a comparison of the energy consumption across systems is revealing, if only at the level of orders of magnitude (Table 1.2). Low input, resource-conserving systems of production are much more energy efficient than the high input systems typical of industrialized countries. Low input or organic rice in Bangladesh, China, and Latin America can produce 1.5–2.6kg cereal per MJ of direct energy consumed. This is some 15–25 times more efficient than irrigated rice produced in the US.

Table 1.1 *Impact of modernization of agricultural systems on yields and direct energy consumption*

Country	*Low input comparison*	*High input comparison*	*Amount of extra yield for high input*	*Amount of extra energy consumption for high input*
Philippines[1]	Traditional rice	Modern rice	+116%	+3000%
	Rainfed rice	Irrigated rice	+150%	+800%
	Irrigated rice with *Azolla*	Irrigated rice with N	+0–30%	+200%
India[2*]	Bullock, rice	Power tiller, rice	+8%	+43%
	Bullock, rice	Tractor, rice	+13%	+74%
	Bullock, wheat	Power tiller, wheal	+12%	+89%
	Bullock, wheat	Tractor, wheat	+6%	+266%
India[3*]	Bullock, rice	Mechanized, rice	+20%	+45%
	Bullock, wheat	Mechanized, wheat	+29%	+138%
US[4]	Low input, maize	Conventional, maize	+0%	+120%
US[5]	Organic, wheat	Conventional, wheat	+29%	+48%
US[4]	Low input, maize	Conventional, maize	+0%	+22%

Note: For the sake of comparisons, the data in this table refer to direct energy use plus indirect energy for manufacturing fertilizers and seeds. These are not comprehensive energy accounts, in which all embodied energy is included. For those marked *, only direct energy is included. 1 Luzon 2 West Bengal 3 Uttar Pradesh 4 Midwest 5 Pennsylvania and New York.

Sources: FAO, 1976; Leach, 1976; Singh and Singh, 1976; Pimental et al, 1989; Berardi, 1978; Ikerd et al, 1992

In industrialized countries the trend has been towards the substitution of inexpensive fuel energy for expensive human labour, so making agriculture a significant energy consumer. Since the 1940s, some 25 million draft animals and 9 million agricultural workers have been replaced in the US; and in the UK, 340,000 jobs have been lost (Berardi, 1978; MAFF, passim). Energy consumption has increased too. According to the OECD (1993), the absolute energy consumption per hectare has increased in OECD countries by 39 per cent from 1970 to 1989. On average, some 1734MJ are consumed per hectare of agricultural land, rising to 46,400MJ for the highest consumer, Japan.

One consequence of this increased substitution of energy for labour in agriculture is a growing contribution to global warming. Agriculture is a major direct source of atmospheric pollution, emitting methane, nitrous oxide, ammonia and the various products of biomass burning (Conway and Pretty, 1991; IPCC, 1990). The single main cause of global warming, however, is carbon dioxide, estimated to contribute about half of the projected warming over the next 50 years. Agriculture contributes to CO_2 production directly through the burning of biomass and indirectly

Table 1.2 *Amount of cereal produced (kg) per megajoule (MJ) of direct energy input different agricultural systems*

Location	*System of production*	*No. of kg cereal produced per MJ of direct energy (+ indirect energy for fertilizers and pesticides used (kg/MJ)*
Japan	Irrigated, high input rice	0.30
China	Organic rice	1.53
Philippines	High input, irrigated rice	0.22–0.36
	Low input, irrigated rice with *Azolla*	0.79
	Rainfed, upland rice	0.72–0.88
Latin America	Low input, upland rice	1.94
Bangladesh	Low input, deepwater rice	2.64
USA	High input, irrigated rice	0.09
USA	High input maize	0.25
	Low input maize, alternative rotations	0.67
UK	Very high input wheat	0.45
	Low input wheat	1.09

Sources: Adapted from IRRI, 1981; FAO, 1976; Walters, 1971; Pimentel et al, 1989; Leach, 1985

through its consumption of energy produced by fossil fuel burning. For each kilogramme of cereal from modernized high input conditions, 3–10MJ of energy are consumed in its production; but for each kilogramme of cereal from sustainable, low input farming, only 0.5–1MJ are consumed. A shift to low input systems could, therefore, have an impact on the process of global warming.

However, there is considerably more energy consumed between the farm and the consumer. In the US, it is said that food travels on average 3000km from farm to plate. In Britain, the production of a 1kg loaf of bread consumes some 20.7MJ (equivalent to 0.48kg of oil), of which 80 per cent is consumed by milling, baking, transport and retailing (Leach, 1976). Making agriculture more energy efficient, by transferring to low input sustainable processes, could only decrease the energy consumed in the remaining 20 per cent. This could reduce the energy consumed in a loaf of bread to 16–17MJ. However, for cereals processed and consumed on the farm, or those passing through fewer processing or transport stages, significant improvements in energy efficiency could be possible following a transition to a more sustainable agriculture.

Pesticide-induced pest resistance and resurgences

The reason for applying pesticides is to prevent pest damage, yet unfortunately they can cause outbreaks themselves. Pesticides can be inefficient for several reasons (Conway, 1971; Risch, 1987). They can cause resurgences by killing off the natural enemies that control pests. They can produce new pests, by killing off the natural enemies of species which hitherto were not pests. And they can induce resistance in pests to pesticides.

Resistance can develop in a pest population if some individuals possess genes which give them a behavioural, biochemical or physiological resistance mechanism to one or more pesticides. These individuals survive applications of the pesticide, passing their genes to their offspring so that with repeated applications the whole population becomes resistant. High and frequent applications of pesticides exert the greatest selection pressure on populations. Resistance has now developed in all insecticide groups and at least 480 species of insect, mite or tick have been recorded as resistant to one or more compounds (Georghiou, 1986). Resistance has also developed in weeds and pathogens. Before 1970, few weeds were resistant to herbicides but now at least 113 withstand one or more products. Some 150 fungi and bacteria are also resistant (WRI, 1994).

Unfortunately, natural enemies appear to evolve resistance to pesticides more slowly than herbivores, mainly because of the smaller size of the natural enemy populations relative to pests and their different evolutionary history (Risch, 1987). The co-evolution of many herbivores with host plants that contain toxic secondary compounds means they have metabolic pathways easily adjusted to produce resistance (Croft and Strickler, 1983). In Sudan, the increasing application of pesticides to cotton over the past 50 years has steadily reduced the number of predator species. One insect, the whitefly, which was formerly kept in check by predators, is now an economically very important pest (Kiss and Meerman, 1991; PT, 1990).

Outbreaks and resurgences are more likely to occur when the landscape has been simplified to contain just a single crop. This may be of cereals, such as wheat or rice, or of plantation crops, such as bananas, cotton or coffee. In Costa Rica, 30 per cent of imported pesticides are used in the production of bananas for export. Bananas are grown in huge plantations, which are highly susceptible to pests and diseases, and there have been repeated cycles since the 1950s of heavy applications of one product, closely followed by pest outbreaks caused by the rapid development of resistance (Thrupp, 1990). When decisions were taken to stop spraying because of inefficiency and growing costs, insect pests rapidly declined: 'two years after insecticides were halted, the previous [predator] species became established again' (C Stephens in Thrupp, 1990). Today's integrated approach to pest management requires greater technical expertise and labour of managers and operators, and now incorporates cultural methods, minimal and selective use of insecticides, and threshold monitoring. Insects rarely now present any problems, though spraying against disease, nematodes and weeds is still heavy.

In Asia, where 90 per cent of the world's rice is produced and consumed, reports of disease and insect outbreaks are numerous (Khush, 1990; Kenmore, 1991; Winarto, 1994). Brown planthopper (*Nilaparvata lugens*, BPH) outbreaks have at various times destroyed hundreds of thousands of ha of rice in countries from India in the west to the Solomon Islands in the east. In Indonesia, the first problems started occurring in 1974. Losses jumped in 1975, after the government started subsidizing pesticides and in 1977 over 1 million tonnes of rice were lost, enough to feed some 2.5 million people (Kenmore, 1991). In 1979, 750,000ha were infested, followed by lower, but not insignificant, levels of infestation of between 20–150,000ha per year during the 1980s. During this period, BPH was only really checked with the release of rice varieties containing genes that confer resistance, though even some of these have been attacked by new biotypes of the pest (Khush, 1990).

Studies in the Philippines and Indonesia have clearly shown that outbreaks occurred after increases in insecticide use (Kenmore et al, 1984; Winarto, 1993). BPH is kept under complete biological control in intensified rice fields that are not treated by insecticides. Even with over 1000 reproducing adults per square metre, the natural enemies exert such massive mortality that rice yields are unaffected. As Peter Kenmore (1991) describes 'insecticide applications disrupt that natural control, survival increases by more than ten times, and compound interest expansion then leads to hundreds of times higher densities within the duration of one rice crop. Trying to control such a population outbreak with insecticides is like pouring kerosene on a house fire.' Other countries in South-East Asia still, however, suffer significant losses to BPH. In central Thailand, some 250,000ha were infested in 1990, the worst year on record.

Pesticides and Human Health Impacts

Mortality and morbidity from pesticides

There is no doubt that pesticides are hazardous. At very high dosages many are lethal both to laboratory animals and people, and can cause severe illness at sublethal levels. But just how serious is the hazard from medium to low dosages is open to question (Conway and Pretty, 1991; IARC, 1991). In the 1950s, 1960s and 1970s organochlorine insecticides were in widespread use in the industrialized countries and high levels of exposure were common in those engaged in their manufacture, in agricultural workers and, because of the presence of residues in foods, among the general public. Nevertheless, there is little evidence of serious ill health, other than as a result of accidental exposure to high dosages. The herbicides 2,4,5-T and 2,4-D were also commonly used in that period, and were originally thought to be a cause of miscarriages. Subsequent, more thorough, studies suggest a link with increased incidence of a certain rare cancer, non-Hodgkin's lymphoma, but not with miscarriages or other reproductive effects (Hoar et al, 1986, 1988; Witt, 1980; Agresti, 1979; Conway and Pretty, 1991).

Other pesticides appear to be intrinsically less hazardous, although the organophosphates, in particular, can cause severe poisoning. These are more acutely toxic than organochlorines but since they are not stored in body tissues are probably less hazardous over the long term. Two highly hazardous pesticides are the nematocide, DBCP, which causes infertility in humans and the herbicide, paraquat, which is carcinogenic and mutagenic. However, many synthetic pyrethroids, and modern herbicides and fungicides, have very low toxicity and no known health effects.

In the industrialized countries, the major hazard lies in accidents. Even then, fatalities at work are very rare – one a decade in the UK and eight a decade in California – and there are many other more common causes of death on the farm. There is, though, a relatively high incidence of ill health among those engaged in applying pesticides. Farmers exposed to organophosphates during the dipping of sheep, for example, appear increasingly to be suffering a wide range of sub-acute health problems.

One problem is that the systems for recording pesticide poisoning vary within and between countries, and are difficult to compare. In the UK, there are at least four institutions collecting mortality and morbidity data, all giving different data (Conway and Pretty, 1991; HSE, 1993). These suggest some 40–80 confirmed cases each year. In California, a comprehensive system of reporting, perhaps the best in the world, records some 1200–2000 cases each year (CFDA, passim). Overall the hazard in the industrialized countries presented by pesticides appears to be not very different from that of other manufactured chemicals, such as pharmaceuticals.

By far the greatest risk, though, is from pesticides in the home and garden where children are most likely to suffer. In California alone, some 6–8000 children of less than six years of age are treated for pesticide poisoning each year. In Britain, some 600–1000 people need hospital treatment each year from home poisoning (Conway and Pretty, 1991). Although, in this respect, pesticides are no different from hazardous medicines, they are often not perceived as being in the same category and are less carefully guarded. Nonetheless, there continues to be considerable public concern over the risks arising from exposure to pesticides, in particular through accidental spraying and spray drift, or from residues in foodstuffs.

Greater hazards in developing world countries

In developing world countries, mortality and illness due to pesticides are much more common relative to the amount of pesticide used. Lack of legislation, widespread misunderstanding of the hazards involved, poor labelling and the discomfort of wearing full protective clothing in hot climates, all greatly increase the hazard both to agricultural workers and to the general public (Conway and Pretty, 1991). Moreover, many pesticides known to be highly hazardous and either banned or severely restricted in the industrialized countries, such as parathion, mevinphos and endrin, are widely available. In 1988, the Food and Drug Administration of the US found that 5 per cent of some 10,000 imported foods when tested were found to contain residues of products banned in the US, indicating continued widespread export and use of such compounds (GAO, 1989).

It is very difficult to say how many people in the South are affected by pesticide poisoning. This is partly because reporting mechanisms are weak, with farmers tending not to seek medical treatment – as is also the case in the North (Dinham, 1993). Most data are gathered by doctors, researchers and activists from individual testimony and hospital records, and so are viewed as anecdotal or circumstantial. This is not to denigrate these reports; it is just that many policy makers do not accept them as sufficiently 'scientific'.

Nonetheless, put together, the data paint a picture more bleak than appeared to be the case in the 1980s (Conway and Pretty, 1991; Dinham, 1993).

- In Malaysia and Sri Lanka, for example, some 7–50 per cent of all farmers reported that they experienced poisoning at least once in their lives (Jeyeratnam, 1990).
- In Thailand, a survey of 250 government hospitals and health centres revealed that some 5500 people were admitted for pesticide poisoning in 1985 alone, of whom 384 died (Jonjuabsong and Hwai-kham, 1991).
- In Latin America, between 10–30 per cent of agricultural workers tested show inhibition of the blood enzyme, cholinesterase, which is a sign of organophosphate poisoning (WHO, 1990).
- In Venezuela, there were 10,300 cases of poisoning with 576 deaths, between 1980–90 (Dinham, 1993).
- In Paraguay, 75 per cent of farmers around Asunción experienced symptoms after spraying (Dinham, 1993).
- In Brazil, 28 per cent of farmers in Santa Catarina say they have been poisoned at least once; and in Parana, some 7800 people were poisoned between 1982–1992 (Dinham, 1993).
- In China, a recent statement from the Agricultural Ministry in China suggested that more than 10,000 Chinese farmers died in 1993 from poisoning by pesticides (Quinn, 1994). Many were said to be victims of home-made cocktails marketed illegally and some 30 per cent of products were unlicensed by authorities. Since 1975, the value of pesticide imports into China has grown from US$76 million to $293 million.

According to the latest (1990) estimates by the WHO, a minimum of 3 million and perhaps as many as 25 million agricultural workers are poisoned each year, with perhaps 20,000 deaths.

Pesticide poisoning and health costs in the Philippines

Recent evidence emerging from the intensive rice-growing regions of the Philippines is confirming this picture of common mortality and illness from pesticides. These areas have greatly benefited from the Green Revolution packages and use of pesticides is still growing, with sales of pesticides increasing by 70 per cent between 1988 and 1992. Between 1980–1987, the National Department of Health Statistics recorded some 4031 cases of pesticide poisoning, including 603 deaths (Casteñeda and Rola, 1990). But this may be an underestimate of the extent of poisoning, as studies are increasingly showing high incidence of poisoning symptoms that go unreported by farmers (Rola and Pingali, 1993; Marquez et al, 1992; Rola, 1989; Loevinsohn, 1987). A recent WHO report recorded 1303 cases of poisoning between January 1992 and March 1993 in one region alone (WHO, 1993).

In one study, Michael Loevinsohn (1987) examined mortality statistics in several contrasting municipalities in central Luzon for diagnosed pesticide poisoning and for other conditions that could be the result of such poisoning. Organochlorines such as endrin and HCH can cause convulsions, so that poisoning may be misdiagnosed as epilepsy, brain tumours or strokes. Similarly, poisoning by organophosphates, such as parathion, can be misdiagnosed as cardiovascular or respiratory diseases.

The study detected a 27 per cent increase between 1961–1971 and 1972–1984 of non-traumatic mortality rates among rural males aged 15–54 years, although in children and women it decreased. This increase closely coincided with the growth in pesticide use. When the figures were broken down, they revealed that deaths in the rural areas diagnosed as poisoning increased by 247 per cent and those from associated conditions by 41 per cent between the two periods, yet mortality from all other causes, except cancer, decreased by 34 per cent. In the case of stroke, mortality increased for all men in both the urban and rural areas, but significantly the increase was greater among young men who are generally at low risk of stroke.

Following the 1982 ban on endrin, mortality attributed to stroke decreased for all men, but the decrease was significantly greater among the younger men in rural areas. The study also revealed that mortality rates had originally peaked each year during August, the month of greatest insecticide use. But after double-cropping became widespread, a second mortality peak appeared in February, at a time when insecticides were used on the newly cultivated dry season crops. These correlations are highly suggestive of occupational exposure to pesticides.

Another important study compared the health status of farmers exposed to pesticides in Nueva Ecija with those unexposed in Quezon. In the exposed group, there were statistically significant increased eye, skin and lung problems. Some 67 per cent of farmers suffered from severe irritation of the conjunctivae (compared with 10 per cent in the unexposed group); 46 per cent suffered from eczema and nail pitting (compared with none in the unexposed); and 46 per cent suffered respiratory problems (compared with 23 per cent in the unexposed). Another study of Nueva Ecija farmers found that 50 per cent of rice farmers suffered from sickness due to pesticide use (Rola, 1989).

Agnes Rola of the University of the Philippines and Prabhu Pingali of IRRI (1993) calculated the health costs of these pesticide problems, taking into account impact on exposed farmers and the costs of restoring individuals to normal health, so as to examine the economics of various pest control strategies. The 'complete protection' strategy, in which some nine sprays are used per season, returned less per hectare than the economic threshold, farmers' practice and natural control strategies (Table 1.3). These results indicate that both farmers and the national economy at large would be better off by cutting pesticide use or eliminating it entirely by adopting more integrated and sustainable practices.

Table 1.3 *Net benefit and health costs of four pest management strategies in lowland irrigated rice, Philippines*

Pest management strategy	*Net benefits, excluding health costs (Pesos/ha)*	*Health costs (Pesos/ha)*
Complete protection: nine applications of pesticide per season	11,846	7500
Economic threshold: treatment only when threshold passed, usually no more than two applications used	12,797	1188
Natural control: pest control emphasizes predator preservation and habitat management, alternative hosts and resistant varieties	14,009	0
Current local practice: 2–3 applications of very hazardous compounds per season	13,847	720

Soil Conservation and Erosion

The causes and costs of erosion

Despite the fact that indigenous systems of soil and water conservation are widespread, well adapted to local conditions, persist for long periods and are capable of supporting dense populations, soil erosion continues to be a problem throughout the world (UNEP, 1983; Reij, 1991; Kerr and Sanghi, 1992; Tato and Hurni, 1992; Hudson and Cheatle, 1993; Pretty and Shah, 1994). Indigenous systems are insufficient alone to prevent agricultural land from continuing to lose productive soil, water and nutrient resources. This is partly because not all farmland is protected by conservation measures, but also because not all erosion arises from farmland. Both roads and urban areas concentrate water flows and non-agricultural areas are also subject to erosion.

Farmers may not be conserving soil and water for a variety of reasons. They may lack the locally appropriate knowledge or skills, particularly if they have been resettled or migrated to new areas. They may be unwilling to invest in conservation measures if the economic costs of conservation are greater than the expected benefits, particularly if the future is uncertain, such as if political instability or conflict threaten the future, or if security of tenure is uncertain. Farmers may be short of labour for construction or maintenance, such as following a decline in population, outmigration in the face of better opportunities for income earning, particularly in urban centres, or simply rising labour costs. They may not be conserving because of the misguided efforts of earlier soil and water conservation programmes. Finally, they may be so responsive to policies encouraging increased food production that they simply ignore the costs.

In Britain, a major cause of soil erosion has been the shift in recent years towards the cultivation of winter cereals, driven by production-oriented policies. The high price of wheat has encouraged winter cultivation in fragile environments and this has led to a massive increase in soil erosion. It was long thought that water erosion was not a problem for British agriculture. But, since the late 1960s, the land sown to winter cereals has tripled, largely at the expense of grassland and spring cereals. Erosion can be of the order of 30–95t/ha in fields where field boundaries and hedges have been removed from critical positions. Bob Evans estimates that some 6200km^2 (4.4 per cent) of land in Britain is now at high risk and some 2100km^2 (1.5 per cent) at very high risk. Erosion is greatest when there is little vegetative cover, such as during winter when winter cereals are being grown; when slopes are long, such as in big fields; and when farmers cultivate up and down slopes, rather than across the contour (Evans, 1990a, 1990b).

On the South Downs in England, for example, erosion was uncommon until winter cereals were widely grown. In the late 1970s, only 5 per cent of these chalk downs were under winter cereals, but this increased to 65 per cent by 1992. In the past ten years, loss of soil accompanied by flooding has caused many incidents of flooding of housing and farms, causing several hundred thousand pounds worth of damage (Boardman, 1990, 1991; Boardman and Evans, 1991; Robinson and Blackman, 1990).

To farmers, erosion reduces the biological productivity of soils and the capacity to sustain productivity into the future. Although soil erosion is clearly costly to economies as well as to farmers, it is difficult to calculate reliably the precise costs (Eaton, 1993; Bishop, 1990). Studies in Mali, Malawi and Java suggest that the costs to farmers are substantial, representing 3–14 per cent of gross agricultural product (Table 1.4).

Off-site costs are also important. Soils are less able to retain water, which runs off more readily into waterways carrying sediments. These block downstream irrigation canals, reservoirs and harbours. Reduced volume means both greater maximum flows and so more likelihood of floods, and reduced minimum flows in dry seasons. The functional lifetime of reservoirs has declined in many countries. And natural systems, particularly fisheries and coral reefs, are threatened by sediments and agricultural pollutants.

In Java, sedimentation costs the economy US$25–90 million each year by shortening the life of reservoirs, reducing hydroelectric output, and increasing maintenance needs for dredging irrigation systems and harbours. In Thailand, a steadily depleting capacity of 20 reservoirs costs US$0.3 million in forgone income from reduced irrigation capacity and in lost hydroelectric capacity. Greater costs, some $18 million annually, are incurred by the need to dredge 19 million m^3 of sediment from the Chao Phraya River to keep the channel open to shipping. These off-site costs can be substantially greater than the financial losses to farmers. At one site in the UK, where soil loss reached 250t/ha, the estimated total loss to the farmers was just £13,000, mostly due to lost seed and fertilizer, compared with £400,000 of damage to housing (Robinson and Blackman, 1990).

Table 1.4 *Selection of the on- and off-site costs of soil erosion*

On-site costs	
Mali (1988)	US$4.6–18.7 million per year Equivalent to 3–13 per cent of agricultural GDP and 1.7 per cent total GDP
Malawi (1980s)	US$25 million per year Equivalent to 14.6 per cent of agricultural GDP and 4.8 per cent total GDP
Java, Indonesia (1980s)	US$320 million per year Equivalent to 3 per cent of agricultural GDP
Off-site costs	
US (1990)	US$10,150 million of damage to freshwater and marine recreation, to water storage, navigation, flooding, fishing, water treatment, irrigation channels, roadside ditches and steam cooling
Cape Verde (1984)	US$2.6 million from a single storm
Java (1980s)	US$25–90 million per year for sedimentation
Thailand (1980s)	US$18 million per year for sedimentation
UK (1982–87):	
Mile Oak, Sussex	£105,000 of damage to housing, plus £150,000 on flood alleviation works
Rottingdean, Sussex	£400,000 of damage to 40 houses, gardens and roads
Breaky Bottom, Sussex	£81,000 of damage to vineyard

More terracing and more erosion

Despite decades of effort, soil and water conservation programmes have had surprisingly little success in preventing erosion. The quantitative achievements of some programmes can appear impressive. In Lesotho, all the uplands were said to be protected by buffer stripping by 1960; in Malawi (then Nyasaland), 118,000km of bunds were constructed on 416,000ha between 1945–1960; and in Zambia (then North Rhodesia), half the native land in eastern province was said to be protected by contour strips by 1950 (Stocking, 1985). In Ethiopia, during the late 1970s and 1980s, some 200,000km of terracing were constructed and 45 million trees planted (Mitchell, 1987).

Ironically, though, many programmes have actually increased the amount of soil eroding from farms. This is because these impressive achievements have mostly been short lived. Because of a lack of consultation and participation, local people, whose land is being rehabilitated, find themselves participating for no other reason than to receive food or cash. Seldom are the structures maintained, so conservation works rapidly deteriorate, accelerating erosion instead of reducing it. If performance is measured over long periods, the results have been extraordinarily poor for the amount of effort and money expended (Shaxson et al, 1989; Hudson, 1991; Reij, 1991).

It is well established that poorly designed structures cause erosion. Yet throughout Africa, little account has been taken of how more terracing can lead to more erosion. In the early 20th century, erosion in Lesotho was not a serious problem in cultivated fields, because grassed field boundaries were well developed and maintained (Showers, 1989). Despite this indigenous practice, contour banks were installed. Local people did not approve, because they reduced the size of fields, and either breached or the outlets developed into gullies. The administration attributed these gullies to *'unusual weather'* (Showers and Malahleha, 1990). Elsewhere in southern Africa, the first anti-erosion measures introduced in the early 1930s were large ridge terraces and bunds. But these imported measures disturbed natural patterns of drainage and permitted storm water to break through at vulnerable points. Careless construction made them susceptible to bursting and locals came to believe that 'gully erosion was caused by the government' (Beinart, 1984).

Narrow-based terraces were introduced into Kenya from the US in 1940 (Gichuki, 1991). For 15 years they were widely used. By 1947, some 4000 hectares were being protected each year and this rate continued until 1956–1957. But these terraces filled up with sediments too quickly, were impossible to maintain and even began to aggravate erosion. And so, by 1958, the number falling into disrepair was exceeding new construction. By 1961, some 20,000ha had fallen into disrepair. Eventually, the authorities recognized the problems and L. H. Brown, the chief agriculturalist, issued a memorandum in 1961 saying that 'narrow-based terraces should be abandoned as policy... we should move to strips of vegetation, preferably grass' (in Wenner, 1992).

Bad contour ridging in the 1960s was worse than none at all in Zimbabwe (then Rhodesia), where farmers say the compulsory construction of ridges caused siltation of rivers. The ridges connected whole fields and drained in a single drainage line, so during large storms, concentrated water into powerful and fast-moving bodies that caused great damage (Wilson, 1989). The same thing has occurred with cut-off drains in Kenya. Their function is to intercept and divert storm water, but many were constructed in a way that caused erosion. 'The most severe mistakes were that cut-off drains were laid and constructed on the wrong sites. They were designed with steep gradients... The water is discharged into gullies which are deepening. The channel ridges were bare and cut-off drains were not supported by other structures below them... All these factors have made the structures more dangerous than useful. More problems were created. Gullies have widened, soil was eroded and crops destroyed' (Hunegnaw, 1987).

Recent project efforts

Graded and contour bunds developed for large-scale farming in the US are widely applied in soil and water conservation programmes in India. Even under heavy subsidies, most small farmers reject them, for very good reasons (Kerr and Sanghi, 1992). These bunds leave corners in some fields and so there is a risk of losing the piece of land to a neighbour. The central water course for drainage benefits only some farmers, damaging the land of others. Contour farming is inconvenient when farmers use multi-row implements, and so is only suitable where the holding is large and tractors are available. Contour bunding without facilities for dealing with surplus water commonly breach, again concentrating water flow that quickly forms gullies. It is, therefore, not uncommon for entire bunds to be levelled as soon as project staff shift to the next village (Sanghi, 1987).

Sometimes, successes are reversed almost immediately. In an evaluation of World Food Programme supported conservation in Ethiopia, the extent of the terracing was said to be 'impressive', yet monitoring in one sub-catchment found 40 per cent of the terracing broken the year after construction (SIDA, 1984). The project had expected that local people would bear all the costs of maintenance. Another example comes from the Yatenga region of Burkina Faso, where 120,000ha of earth bunds constructed at high cost with machine graders in the early 1960s have now all but disappeared (Marchal, 1978, 1986). In the Majjia and Badéguicheri valleys of Niger, most of the 6000ha of earth bunds constructed between 1964–1980 are in an advanced state of degradation (Reij, 1988). In Sukumuland, Tanzania, where contour banks, terraces and hedges were forced upon farmers, almost no evidence remained of these conservation works by the early 1980s and now 'erosion is extremely severe' (Stocking, 1985).

In Oaxaca, Mexico, a large-scale government soil conservation programme is also establishing contour bunds based on the US models. It is an area noted in the 1970s and 1980s by various 'expert' missions as having 'massive soil erosion' and 'the world's worst soil erosion'. But recent evidence is suggesting that erosion has only become serious following the imposing of terraces and bunds (Blackler, 1994). Rill erosion has been recorded within one year of their establishment and degradation has been so severe that less than 5 per cent of the bunded area is cropped.

In Cape Verde off the west coast of Africa, the state takes responsibility for erosion control by paying farmers to work on their own land. The result is that traditional practices are ignored as farmers take the money without influencing the project. *Socalco* terraces, for example, are built from top to bottom of steep slopes, with the result that foundations are often left hanging in the air (Haagsma, 1990). As Ben Haagsma has put it 'this does not stimulate … good cooperation between farmers and MDRP [the project]. It is difficult to eradicate the attitude "MDRP knows best".' In India, farmers have only permitted bunds to be constructed on their fields because they are attracted to subsidies. The impact on the relations between government and farmers is serious: 'in most villages farmers have become addicted to subsidies which normally come as part of development projects.' (Sanghi, 1987).

The impact of these programmes has been to make many things worse. A failure to involve people in design and maintenance can create considerable long-term social impact. The enforced terracing and destocking in Kenya, coupled with the use of soil conservation as a punishment for those supporting the campaign for independence, helped to focus the opposition against both authority and soil conservation (Pretty and Shah, 1994; Gichuki, 1991). This led, after independence, to the deliberate destruction of many structures because of their association with the former administration (Anderson, 1984). In neighbouring Somalia, a large Food and Agriculture Organization (FAO)-funded project constructed dams during the 1970s to check gullies, but because of poor construction, many collapsed or diverted the floods, so accelerating gully erosion instead of preventing it. This induced widespread disenchantment amongst local people for all conservation projects that followed (Reij, 1988). Such attitudes are a critical constraint for many current soil conservation programmes.

The Loss of Biodiversity

Why farmers prefer diversity

Farmers of traditional and low input agricultural systems have long favoured diversity on the farm. Today, there is still a huge variety of mixtures cultivated, including cereals, legumes, root crops, vegetables and tree crops. In Africa more than 80 per cent of all cereals are intercropped, producing in some cases highly complex patterns on the ground, with up to 20 species grown in close proximity (Vandermeer, 1989; OTA, 1988). In Latin America, about 60 per cent of maize is intercropped and 80–90 per cent of beans are grown with maize, potatoes or other crops (Francis, 1986). In one field in the Andes in Peru, Robert Rhoades recorded some 36 potato varieties growing in 13 rows (Rhoades, 1984). These were all shapes and sizes, and a variety of colours, including black, red, blue, purple, yellow and white. Altogether some 3000 traditional varieties are still grown by Andean farmers.

In very variable conditions, farmers rarely standardize their practices. They maintain diversity, develop a variety of strategies and so spread risk. Mixtures of crops and varieties clearly provide farmers with a range of outputs, and also represent logical approaches to coping with variable environments. Mixed crops can also be less variable in time and space, and combined yields are often greater, particularly if differences in root and shoot geometry allow the crops to use light, nutrients and water more efficiently (Vandermeer, 1989; Francis, 1986; Rao and Willey, 1980; Trenbath, 1974). Intercropping can reduce weed problems, so influence labour requirements; returns to labour can be increased; and erosion and runoff may be reduced by the greater ground cover given by the mixture (OTA, 1988).

Farmers themselves recognize the value of mixtures. In Indonesia, farmers in rainfed conditions plant a greater mix of crop combinations during the more risky seasons (Castillo, 1992). In the dry season, they plant 42 combinations; in the uncertain middle season, they use 25; and in the rainy season, they plant just 7. The author of a recent comprehensive review of intercropping, John Vandermeer, has put it: 'In personal conversation with [farmers] in southern Mexico, Costa Rica and Nicaragua, I have frequently … been told that two crops make a good combination because one is taller than the other and "fits in" to the spaces where the other does not, or that the root systems go to different depths and thus use nutrients from different parts of the soil.' Such popular knowledge is common.

It is, however, impossible to say categorically whether a mixture will result in better yields than the monocropped alternatives, except perhaps for legume–non-legume mixtures (Trenbath, 1976; Willey, 1979; Vandermeer, 1989). Much depends upon the local conditions and characteristics of the crops themselves. Pest attack is frequently reduced in intercrops, because of a variety of factors (Risch et al, 1983). Host plants are more widely spread and so harder to find; one species may trap a pest; or one species may repel the pest; and/or predators may be attracted. Weeds are also more likely to be suppressed by mixtures.

Recent surveys of non-irrigated rice systems in Cambodia, Indonesia, Laos, Madagascar, Myanmar, Nepal, Philippines and Thailand have found that farmers manage their highly diverse conditions with different land use strategies (Fujisaka, 1990, 1991; Fujisaka et al, 1992). Farmers described different combinations of landscape position, soil type, hydrology, and flood and drought risk, and showed how they matched these to different combinations of rice varieties and management practices. In upland Laos, for example, farmers distinguished 20 different types of soil. Each grew up to four varieties of rice, with 29 varieties grown in the two regions of Luang Prabang and Oudomasay. But these mixes are not static. Farmers are continually experimenting with new varieties or readopting old or existing ones. In Bukidnon, Philippines, farmers were cultivating 18 varieties, having dropped another six in recent years.

In Myanmar, 52 different varieties of rice were encountered in rainfed uplands and lowlands, and in deepwater conditions. Each farmer does not seek to maximize yield, nor do they have one preferred variety. They grow up to six varieties each, with a range of different taste, colour, pest resistance, growth pattern, duration, flood/drought tolerance, milling recovery and market price qualities (Table 1.5).

The decline under modernization

It is only recently that fields monocropped to single species and varieties have become common. The introduction of modern varieties and breeds has almost always displaced traditional varieties and breeds. During the 20th century, some 75 per cent of the genetic diversity of agricultural crops has been lost. Only about 150 plant species are now cultivated, of which just three supply almost 60 per cent

Table 1.5 *Numbers of rice varieties and their qualities encountered in three non-irrigated rice regions of Myanmar*

Region	*Number of varieties*	*Qualities of rice varieties*
Rainfed uplands	18	115 to 180-day duration red and white glutinous and sticky long and short awned and awnless drought tolerant and intolerant 100–150cm in height for eating or for rice wine grain size length of time in stomach yields from 1.0 to 2.0t/ha
Deepwater rice	18	elongation from water panicle in or out of water expansion when cooked eating quality yellow and white resistance to stem borer yield from 1.5 to 1.8t/ha
Rainfed lowlands	16	125–200 day duration flood or drought tolerant glutinous or not yellow, white or black length of time in stomach fertilizer responsiveness distinctive aroma expansion when cooked yields from 1.2 to 6.2t/ha

Source: Fujisaka et al, 1992

of calories derived from plants (FAO, 1993; Fowler and Mooney, 1990). The trend has been rapidly downwards in many countries (Table 1.6). In India, once more than 30,000 rice varieties were grown, but now just 10 cover 75 per cent of the whole rice area. A comprehensive study of the decline in the US this century has been conducted by Cary Fowler and Pat Mooney (1990), where 'the losses of fruit and vegetable varieties are staggering'. For 65 types of vegetable, they record a consistent loss of between 80–100 per cent of the varieties of each since the turn of the century. Of the 8207 varieties listed for these vegetables in 1903, only 607 are now held by the National Seed Storage Laboratory.

Most modern scientists have seen mixtures as a problem to be overcome. When the Rockefeller-sponsored team first visited Mexico in the 1940s to assess wheat cultivation as a precursor to establishing the national wheat breeding programme, the low-yielding traditional fields were condemned because: 'most fields were a mix of many different types, tall and short, bearded and beardless, early ripening and

Table 1.6 *Decline in diversity of crops and livestock in a selection of locations*

India	Once more than 30,000 rice varieties grown; now expected that just 10 rice varieties will soon cover 75 per cent of rice area.
Philippines	Before the modernization of early 1970s, 3500 varieties of rice existed; now only 3–5 are grown in irrigated areas.
Europe	Half of all the breeds of domestic animals (horses, cattle, sheep, goats, pigs and poultry) have become extinct since the beginning of the 20th century; a third of the remaining 770 breeds are in danger of disappearing by 2010.
France	71 per cent of apple production from one variety, Golden Delicious; 30 per cent of bread wheat from 2 varieties and 70 per cent from 10 varieties; In the SE, the Provençal diet contained 250 plant species at beginning of 20th century; now it comprises only 30–60.
Greece	95 per cent of local wheat varieties lost since 1920s.
The Netherlands	A single potato variety covers 80 per cent of potato land; 90 per cent of wheat planted to 3 varieties; 75 per cent of barley planted to 1 variety.
UK	68 per cent of early potatoes planted to 3 varieties; 4 wheat varieties account for 71 per cent of wheat area.
US	Since 1900: 6121 apple varieties lost (85 per cent) 2354 pear varieties lost (88 per cent) 546 garden pea varieties lost (95 per cent) 516 cabbage varieties lost (95 per cent) 394 field maize varieties lost (91 per cent) 383 pea varieties lost (94 per cent) 329 tomato varieties lost (81 per cent) 295 sweet corn varieties lost (96 per cent) Now: 71 per cent maize area planted to 6 varieties 96 per cent pea area planted to 2 varieties 65 per cent rice area planted to 4 varieties 76 per cent snap bean area planted to 3 varieties

Sources: Pimbert, 1993; FAO, 1993; Soetomo, 1992; Fowler and Mooney, 1990

late ripening; fields usually ripened so unevenly that it was impossible to harvest them at one time without losing too much over-ripe grain or including too much under-ripe grain in the harvest' (Stakman et al, 1967). These mixtures of traditional varieties may not have yielded well, but did give some insurance against pest and disease attack. Modern wheat varieties introduced in Mexico in the 1940s and 1950s were soon susceptible to new races of rust, and were quickly overcome.

Similar simplification occurred during rice modernization in Asia. In Central Luzon, Philippines, for example, all 25 varieties grown by farmers in the mid-1960s were traditional varieties. By 1980, the total number of varieties grown had fallen only to 19, but just two were traditional (Cordova et al, 1981). Some 95 per cent of the rice area is now planted to modern varieties. In the US, mixtures of wheat and oats, oats and barley, sorghum and alfalfa, maize and soybean were common in the early part of this century (Thatcher, 1925; Bussell, 1937; Bailey, 1914). All these are now mainly grown as monocrops. Mostly it has been the incentive structures provided by cheap and available inputs that has encouraged farmers to specialize. But in some countries, farmers have been prevented by law from growing traditional varieties and there have been reports of traditional crops being burned or destroyed (Soetrisno, 1982).

With these losses of genetic diversity could go future opportunities. Locally adapted crops or livestock can be critical for helping to deal with particular challenges brought by pests or diseases. One rice variety from India, for example, has been central to efforts to cope with a devastating virus. During the 1970s, the grassy-stunt virus devastated rice from India to Indonesia. After a four-year search, in which over 17,000 cultivated and wild rice samples were screened, disease resistance was found. One population of the wild species, *Oryza nivara*, growing near Gonda in Uttar Pradesh, was found to have a single gene for resistance to grassy-stunt virus strain 1. Today, resistant rice hybrids containing the wild Indian gene are grown across some 110,000km^2 of Asian rice fields (FAO, 1993). Genetic erosion, the reduction of diversity within a species, is a global threat to agriculture.

The value of wild diversity

The value of wild biodiversity to farming households has seldom been recognized by agriculturalists (Jodha, 1990; Bromley and Cernea, 1989; Scoones et al, 1992). Wild resources are often called wastes or wastelands, and represent a symbol of backwardness and underdevelopment. During the British agricultural revolution of the 17th to 19th centuries, common resources were seen by many officials as the 'trifling fruits of overstocked and ill-kept lands' (in Humphries, 1990), and 'mere sand … and fit for nothing but rabbits' (Burrell, 1960); and to large landowners, commons 'burdened a village with beggarly cottages and idle people. They were better enclosed [for agriculture]' (in Thirsk, 1985). In India, common resources are still called wastelands.

It is well recognized that hunter–gathering communities, such as the !Kung San in Botswana or Indian groups in the Amazon, depend on wild resources for their complete livelihoods. What is less widely recognized is that farming households also rely heavily on wild resources (Table 1.7). If wild habitats are lost, these resources will no longer be available to rural households. And those who will suffer most are the poorest, who most often rely on wild resources as key sources of food, fuel, medicines and fodder.

Many agricultural institutions were indicating during the 1980s that agricultural area would have to expand substantially if growing world populations would be fed (TAC, 1988). More recently, these calls have been toned down, as it is being increasingly recognized that expansion on this scale will incur significant costs to rural households and national economies alike.

Table 1.7 *Use of wild plants for food and medicine by farming communities*

Location	*Importance of wild resources*
Brazil[1]	Kernels of babbasu palm provide 25 per cent of household income for 300,000 families in Maranhâo State
China, West Sichuan[2]	1320 tonnes of wild pepper production; 2000t fungi collected and sold; 500t ferns collected and sold
Ghana[3]	16–20 per cent of food supply from wild animals and plants
India, West Bengal[4]	155 wild plants collected for food, fodder, medicine and fuel
Kenya, Bungoma[5]	100 species wild plants collected; 47 per cent of households collected plants from the wild and 49 per cent maintained wild species within their farms to domesticate certain species
Kenya, Machakos[6]	120 medicinal plants used, plus many wild foods
Nigeria, near Oban National Park[7]	150 species of wild food plants
South Africa, Natal/KwaZulu[8]	400 indigenous medicinal plants are sold in the area
Sub-saharan Africa[9]	60 wild grass species in desert, savanna and swamp lands utilized as food
Swaziland[10]	200 species collected for food
Thailand, NE[11]	50 per cent of all foods consumed are wild foods from paddy fields, including fish, snakes, insects, mushrooms, fruit and vegetables
South west of US[12]	375 plant species used by native Indians
Zaire[13]	20 tonnes chanterelle mushrooms collected and consumed by people of Upper Shaba
Zimbabwe[14]	20 wild vegetables, 42 wild fruits, 29 insects, 4 edible grasses and one wild finger millet; tree fruits in dry season provide 25 per cent of poor people's diet

Recent responses to support farmers

When external agencies work closely with farmers to document the variety and performance of their crops, the results can be extraordinary (Salazar, 1992; Fowler and Mooney, 1990). Many have found varieties that perform well in low external input conditions (Box 1.1). The Phrey Phdau rice research station in Cambodia, for example, has collected 1320 local rice varieties with the help of Oxfam. One local variety, *2-Somrung 2*, yields 5t/ha under low-external input conditions. Another, Prambei Khor, compares equally with IR42 on yield terms, and has superior straw production and grain quality. In Thailand, the non-governmental organization (NGO) Technology for Rural and Ecological Enrichment (TREE) has collected

Box 1.1 *The role of the group 'Farmer-Scientist Participation for Development' (MASIPAG), Philippines in the conservation of biodiversity*

The MASIPAG programme was established in 1986 to encourage farmers' participation in the development of improved varieties which yield well under low-external input conditions. The programme has:

- collected 210 accessions from farmers around the country;
- made cross-combinations to produce 101 selected lines by 1990; of these half showed good yield potential under low input conditions;
- distributed 40,000kg of seed selected from 34 cultivars around the country;
- produced varieties that yield 3.7–5.7t/ha with no applications of fertilizer or pesticides; this compares with a range for MVs needing external inputs of 3.2–5.2t/ha.

Source: Salazar, 1992

4000 accessions of rice in two years, which have been stored in the National Rice Germplasm Bank pending the development of community seed banks (Salazar, 1992; Siripatra and Lianchamroon, 1992).

Once again, the clear principle is that farmers, given the choice, rarely replace local varieties entirely with a single MV. They prefer to add a MV to their existing mix of options. In Indonesia, a local variety called *Rojolele* was found that compared well with IR64, a recent release from International Rice Research Institute (IRRI) (Soetomo, 1992). IR64 yields better but, because it needs more water, weeding and fertilizer, it gives lower returns to farmers. *Rojolele* is also favoured for its distinctive taste and fragrance, as well as being fairly resistant to brown planthopper, rats and birds, unlike IR64. Farmers can also produce it locally in community seed banks, which are growing in popularity in Indonesia, despite them being contrary to existing government policy that holds that germplasm should be managed only in official genebanks.

When farmers are given the choice about new varieties, they much prefer to absorb the new technology into their existing systems. This is quite different to the way that agricultural modernization has worked so far, with farmers having to adopt the whole package or nothing at all. Recent participatory research with women farmers in Andhra Pradesh conducted by International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) scientists led by Michel Pimbert has shown how important is the principle of supporting local biodiversity. Women experimented with new varieties of pigeonpea that were resistant to the pod borer, *Helicoverpa armigera*, which can devastate whole crops in bad years (Pimbert, 1991). Although some varieties were rejected because of bitter taste, interest was generated by the resistance to pod borer. Women farmers, though, said they would not replace their traditional varieties, but incorporate the new varieties of pigeonpea into their current mix of landraces. The new technology, in this case, has been adapted to suit local farming and livelihood conditions.

The Breakdown of the Social Fabric of Rural Communities

The social costs of modernized agriculture have been widely documented. As agriculture has increasingly substituted external inputs and resources for internal ones, so there has been a decline in the number of jobs for local people. Standardization has reduced the range of management skills needed, and many decisions have been taken out of the hands of farmers and local institutions.

Agricultural modernization has helped to transform many rural communities in both industrialized and developing world countries. The loss of jobs, the further shift of economic opportunity away from women to men, the increasing specialization of livelihoods, the increasing concentration of land in the hands of wealthy villagers and urban investors, the growing gap between the well-off and the poor, and the co-option of village institutions for the purposes of the state, have all been features of this transformation.

Social change in rural Britain

A period of remarkably successful agricultural growth since the mid-20th century has brought significant social change in rural areas of Britain (see, e.g. Newby, 1980). As farming has intensified its use of external inputs, so it has shed jobs, bringing poverty and deprivation to many people. Between 1945 and 1992, the number of farms in England and Wales has fallen from 363,000 to 184,000, while the total area of agricultural land has remained stable at 19 million ha. Over the same period, the number of regular hired and family workers on farms in England alone fell from 478,000 to 135,000 (MAFF, passim). In the past decade, there have been dramatic falls in the numbers of most types of people engaged in farming activities throughout Britain (Table 1.8). It is expected that the number of people

Table 1.8 *Changes in labour force (in thousands) on agricultural holdings in the UK, 1981–92*

Class of worker engaged agriculture	*1981*	*1992*
Total labour force (in thousands)	709.9	621.8
Total farmers, partners, directors	293.6	280.5
Spouses of farmers, partners and directors doing farm work	74.6	76.0
Salaried managers	7.9	7.8
Regular hired whole and part-time workers	182.2	124.9
Regular family workers	54.5	46.4
Seasonal or casual workers	97.0	86.2

Source: Pretty and Howes, 1993, using MAFF Agricultural Statistics from Agricultural and Horticultural Censuses, prepared by Government Statistical Service, Guildford engaged in agriculture will fall by a further 17–26 per cent during the 1990s (in DoW, 1992). Now, as a result of modernization, some of the worst poverty is in rural areas (Pretty and Howes, 1993).

In the quest for greater food production, landscapes have been homogenized, and rural livelihoods and farming systems have been progressively simplified. Where there were diverse and integrated farms employing local people, there are now operations specializing in one or two enterprises that largely rely on farm or contractor labour only. Where processing operations were local, now they are centralized and remote from rural people. The result is that few people who live in rural areas have a direct link to the process of farming. Fewer people make a living from the land and, of course, they understand it less. The lack of employment has also coincided with the steady decline in rural services, such as schools, shops, doctors and public transport.

However, the number of people in rural areas is increasing, though it appears that it is younger people migrating away, to be replaced by older, particularly retired, new entrants (DoW, 1992). More people want to move into rural areas too. Recent surveys found that 76 per cent of those who live in cities want to live in a village or country town and 37 per cent expect to move out during the next decade (Rose, 1993). The rural community, bonded in the past by a common understanding and economic interest in the land, currently appears unlikely to be brought together by close links with farming.

Various national enquiries have shown that the incidence of rural poverty is considerably greater than previously supposed (DoW, 1992; HL, 1990; ACORA, 1990). According to an unpublished government report, some 25 per cent of rural households are living on or below the official poverty line (in DoW, 1992). Farmers and farmworkers are about twice as likely to commit suicide than the rest of the population, and suicide is the second most common form of death for male farmers (in DoW, 1992). Farmers are increasingly recognized as suffering the stress and deteriorating confidence associated with lonely occupations (Martineau, 1993; Cornelius, 1993). The Duke of Westminster's report (1992) described these problems in this way: 'Hidden in the rural landscape which the British so much love, people are suffering poverty, housing problems, unemployment, deprivation of various kinds, and misery. Traditional patterns of rural life are changing fast, causing worry, shame and distress. Those most affected are often angry and bitter but feel they have little chance of being heard. The suicide rate is very high. Neither the public nor the private sector is showing any signs of caring very much about all this.'

Small family farms have been especially vulnerable (Lobley, 1993; Moss, 1993). They rely more on diverse sources of off-farm income and so are dependent upon the wider success of the rural economy. When small farms are given up, they tend to be amalgamated into ever larger holdings, with a resulting radical change in the landscape structure (Munton and Marsden, 1991). Many successions lead to intensified land use, and the removal of woods and hedges. Continuity of farms is a goal held by many farm families. Most wish to see their heirs as successors. Yet, the evidence suggests that few will do so. Since the late 1960s, the proportion of farmers planning to pass their businesses to their heirs has fallen from about 75 per cent to 48 per cent (Ward, 1993). Succession is also less likely for farmers in the less prosperous areas (Marsden et al, 1992). Farming's declining economic fortunes seems to have eroded the commitment to successors in family farming and the prospect of a farming career appears to have become less attractive to farm children.

Changes in Japan and the US

These changes are mirrored by social changes in other industrialized countries. In Japan, similar threats to rural culture are occurring. More than half of farmers are older than 60 years of age and 75 per cent are part-time, relying on jobs in manufacturing as their main income source. Only 16 per cent of all farms have a male under 60 years devoting more than 150 days each year to farming (Ohnox, 1988). Like many other parts of the world, the next generation shows little interest in the labour-intensive work of farming: 70 per cent of farms have no successor. The number of farm households has fallen from 5.82 million in 1960 to 4.2 million in 1991. In that time, the number of people living in a farming household has fallen from some 34 million (30 per cent of the population) to just under 17 million (14 per cent of population) (Iwamoto, 1994; MAFF, passim).

One woman farmer of a 0.2ha plot on the outskirts of Tokyo says her son, who works in an electronics factory, wants her and her 70-year-old husband to retire and sell the land to property developers: 'the young are not interested in the old ways and the old values. We have always owned land, it is the foundation and strength of our family. Our son says the land should be sold for building, or as a car park, but we believe everyone benefits from having farmers in the heart of the city' (in Davies, 1992). However, many say that looking down on their tiny plots of land from their tower blocks has helped them protect their sanity. Farmers fear that their rice culture is under terminal threat: 'people are lamenting the coming extinction of the two thousand year rice culture of Japan' (Furusawa, 1988). Nonetheless, it is also true that this culture has been heavily protected by national policies.

Just as in Britain and Japan, there have been huge changes in rural culture during this century in the US. Since 1900, the proportion of the national population who are farm residents has fallen from 40 per cent to just 1.9 per cent, or 4.6 million people (AAN, 1993). Family farms have been consolidated into larger farms; labour opportunities have fallen; and farm enterprises have been concentrated in fewer hands. This modernization has been most visible in the declining number of farms and the replacement of family farming by modern large-scale farming. But it has also had significant impacts on social systems.

A classic study conducted in 1946 by Walter Goldschmidt showed what happens when the social structure in the countryside changes during modernization (Goldschmidt, 1978). He studied the two rural Californian communities of Arvin and Dinuba in the San Joaquin Valley. These were matched for climate, value of agricultural sales, enterprises, reliance on irrigation and distance from urban areas. The differences were in farm scale: Dinuba was characterized by small family farms, and Arvin by large, commercialized farms. There were striking differences between the two communities. In Dinuba, there was a better quality of life, superior public services and facilities, more parks, more shops and retail trade, more diverse businesses, twice the number of organizations for civic improvement and social recreation, and better participation by the public. The small farm community was a better place to live 'perhaps because the small farm offered the opportunity for "attachment" to local culture and care for the surrounding land' (Perelman, 1976). A study of the same communities in the late 1970s reaffirmed these findings (Small Farm Viability Project, 1977).

Recent years have brought severe financial crises for family farmers. They were squeezed by debt and low product prices. Many thousands lost their businesses. Many others did not see this as a problem, but as desirable. It was widely perceived to be the way to agricultural prosperity. Michael Perelman (1976) quotes a Bank of America official who said in 1969 'what is needed is a program that will enable the small and uneconomic farmer – the one who is unwilling or unable to bring his farm to the commercial level by expansion or merger – to take his land out of production with dignity'.

Small farmers were widely taken to be economically inefficient. But their loss has been a severe loss to rural society. Linda Lobao's study (1990) of rural inequality shows the importance of the locality that Goldschmidt illustrated. The changing structure of farming has brought a decline in rural population, increased poverty and income inequality, lower numbers of community services, less democratic participation, decreased retail trade, environmental pollution and greater unemployment. The decline of family farming does not just harm farmers. It hurts the quality of life in the whole of society. Corporate farms are good for productivity, but not much else: 'this type of farming is very limited in what it can do for a community … we need farms that will be viable in the future, correspond to local needs and remain wedded to the community' (Lobao, 1990).

Wendell Berry, the influential poet and farmer, has long drawn attention to what happens during modernization. Agricultural crisis is a crisis of culture: 'A healthy farm culture can be based only upon familiarity and can grow only among people soundly established on the land; it nourishes and safeguards a human intelligence of the earth that no amount of technology can satisfactorily replace. The growth of such a culture was once a strong possibility in the farm communities of this country. We now have only the sad remnants of those communities. If we allow another generation to pass without doing what is necessary to enhance and embolden the possibility now perishing with them, we will lose it altogether.' (Berry, 1977)

One indicator of the crisis is the suicide rate among farmers. In the Midwest, suicide rates among male farmers were twice the national average during the 1980s (Gunderson, in FW, 1991). Some 913 took their own lives between 1980–1988, producing annual rates higher than for any other documented occupation.

Mexican Indians and modern agriculture

After centuries of avoiding incorporation into the wider culture of what is now Mexico, the Yaqui Indians of Sonora, situated in the north of Mexico and bordering the Gulf of California, have been entirely changed by rapid integration into the modern way of farming (Hewitt de Alcantara, 1976). They had been known for their tradition of strong social cohesion, cultivation of a great diversity of crops, and the use and management of wild foods, including wild fruits and oysters. They relied on small-scale water harvesting and irrigation structures to irrigate their crops from the seasonal rivers. But this has all changed.

In the 1940s, modern water control projects at Potam in the Yaqui Valley began to divert water to commercial farms. As more water was removed, the river ran low, making many families' plots unusable. Yaqui agriculture began to be undermined as they were coerced into joining the government scheme so as to have access to water. At the time, the state was trying to assure the permanent tranquillity of the tribe, and it was felt that commercializing Yaqui agriculture through water control and the formation of collective credit societies would help. During the 1950s, farmers were grouped into 40 credit societies, each containing some 30 members and their plots were joined to form the common land for each society. But external banks were given complete control of all farming decisions. Farmers had to grow wheat and cotton, and soon only 10 per cent of land was left under maize-beans-squash, with 90 per cent under wheat and cotton. The varied production of fruit and vegetables noted by visitors 20 years earlier had disappeared.

The local people had lost control over their own land, and the social and economic changes were significant. 'Instead of preparing and working their family plots by hand, using seeds from previous crops and silt from periodic river floodings, Yaqui cultivators found themselves observing the march of tractors and combines driven by bank employees across common land planted with high-yielding seeds and fertilized with chemical products. Most Yaqui indians intervened themselves only occasionally, when some menial task like cleaning irrigation canals or picking cotton demanded unskilled labour.' (Hewitt de Alcantara, 1976)

As a result of complete control by federal employees and no local participation or involvement, feeder canals soon became blocked, land badly levelled, fertilizer applied incorrectly and planting dates missed. Yields of wheat were too low to repay the loans which local credit societies had forced them to take on. All local households were heavily in debt in the early 1960s. Despite the Yaqui's fear of water, the government tried to set up a fishing cooperative. This failed. They tried a cattle cooperative, but this was run by a local bank and so lands were quickly overgrazed.

By the early 1970s, the whole process had thoroughly undermined traditional institutions, not least the family. It had ceased to be a productive unit, and its disintegration had led to clashes between the old and young, and a weakening of traditional religious and cultural components of life. Ceremonies previously good at maintaining a relatively equal distribution of wealth had broken down. A group of landless had appeared. Those made wealthy were mainly the shopkeepers, who were *mestizos* from outside the community. A few large farmers had appeared, utilizing hired labour only during peak seasons and occasionally renting additional land. About the only communal activity that remained was the cooperation for *fiesta* celebrations. As Cynthia Hewitt de Alcantara (1976) noted, such integration with the surrounding mestizo culture was no doubt inevitable, but 'the way in which it was enforced seriously damaged a tradition of economic and social democracy, local self-government, and community service which should have been valued at least as highly as material progress. More to the point, the modernization of Potam undermined these attributes without really bringing material prosperity at all – except to a very few.'

Social change in Indonesia

One of the earliest technological changes during rice modernization was the replacement of the traditional *ani-ani* knife with sickles and scythes for harvesting (Collier et al, 1973; KEPAS, 1984). By tradition, Javanese and Sundanese rice farmers did not restrict anyone wishing to participate in the rice harvest. The harvesters were mostly women from their own and neighbouring villages. They used the *ani-ani*, a small hand knife, to cut each stalk of rice separately. The rice sheaves were carried to the owner's house, where the harvester would receive a share of the harvest. In this *bawon* system, the owner kept seven, eight or nine shares to one for the harvester.

With the adoption of MVs with their short straw and simultaneity of maturation, rice could be harvested much more quickly by sickle or scythe. Owners increasingly adopted the new *tebasan* system of cash-and-carry for harvesting, in which the standing rice crop was sold to a trader, who then arranged for harvesting. With these changes, bands of men increasingly became itinerant harvesters and opportunities for income generation for women fell. Many were entirely excluded from the process of harvesting. In some parts of Java, there were 200 or more women harvesting each hectare of rice in 1970. By 1990, they had been replaced by 10–20 men (Salazar, 1992). At the Agro-Economic Survey at Bogor, Collier and his colleagues calculated that women's share of the harvest fell from 65 per cent in the 1920s to 37 per cent in the late 1970s (Collier et al, 1982).

But modern technologies have affected more than just women alone. The two-wheeled tractor is now used extensively in land preparation, and water pumps and tube wells have been introduced for irrigating rice. The potential impact of this mechanization can be gauged by the calculation that if all these modern mechanization techniques were introduced to Java, then over 3 billion person-hours of labour would be lost (Collier et al, 1982). This is equivalent to 2 million full-time employees or many more part-time workers.

In the early 1980s, Loekman Soetrisno and colleagues (1982) interviewed landless and nearly landless farmers in a well-irrigated and apparently prosperous village in Central Java. They were asked how agricultural development had affected their lives: 60 per cent answered that 'development has made us in a difficult position'. They said they were confused by the various government regulations, saying in particular that two were unfair. These were that all farmers in the village had to plant modern varieties on their rice paddies and that they had to follow a strict cropping schedule. Farmers appreciated the rationale, but could not abide by the regulations. They could not afford the modern inputs. They also 'did not have the courage not to abide by the regulations, as this would mean direct confrontation with the village bureaucracy'. They reported to Soetrisno that in 1978 one small farmer had to burn his rice when the local officials found out that he was planting a local variety.

The order to all farmers to plant rice in a fixed schedule had a major impact on social structure too. Unlike the richer farmers, the poorest did not have buffaloes or cows to help them plough the land. Neither could they hire extra labourers to work on their land. It was also the custom that before small farmers prepared their land, they would work first for richer farmers for the additional income. The new regulation prevented them from earning this income. As a result, they had to rent their land to richer farmers and become tenants on their own land, with the resulting loss of social status in the community. One January, this village was featured on national television news as 60 people had been found suffering from severe malnutrition. According to the village head, most of these were landless and small farmers (Soetrisno, 1982).

The decline of the traditional *sawah* system of rice production in Bali is an example of what can happen when a sustainable system is changed (Poffenberger and Zurbuchen, 1980). It was self-sufficient within the boundaries of a single watercourse. Complex social, ecological and economic linkages made the system sustainable and resilient for at least 1100 years. But, over just a few years, rice modernization broke apart these local relationships by substituting external processes. Pesticides replaced predators, and fertilizers replaced cattle and traditional land management. Government officials made decisions rather than local institutions, and local labour groups were replaced with specialist workers and tractors (Box 1.2).

Wheat and pastoralists in Tanzania

Another example of the social damage caused by modern farming comes from Tanzania, where millions of dollars of Canadian aid were spent between 1969 and 1993 in developing wheat farms on the dry Basotu Plains. Yields were comparable with those on the Canadian plains and the farms came to supply nearly half of the national wheat demand. But the plains are also the homeland of some 30–50,000 Barabaig pastoralists. The impact on their lives of these wheat farms has been recorded at first hand and documented in depth by Charles Lane (Lane, 1990, 1993, 1994).

The Barabaig economy is based on livestock production. Their herds of cattle, sheep and goats utilize the forage, water and salt licks found scattered throughout

Box 1.2 *The impact of modernization on the traditional wet rice cultivation system of Bali*

Wet rice has been cultivated in Bali since at least AD882. Irrigation cooperatives, the *subaks*, are responsible for the allocation of water and the maintenance of irrigation networks, as wet rice is too complex for one farmer to practise alone. Each *subak* member has one vote regardless of the size of landholding. Soil fertility is maintained by the use of ash, organic matter and manures. Rotations and staggered planting of dry and wet crops control pests and diseases. Bamboo poles, wind-driven noise-makers, flags and streamers scare off birds. And rice is harvested in groups, stored in barns and traded only as needs arise. Rice yields are typically 1–2t/ha, and sometimes as high as 3t/ha.

Modernization depends on the adoption of the whole new package. The major impacts have been as follows.

- Yields could be 50 per cent greater than under the traditional system, but only under optimum conditions, as the new rice was more susceptible to climatic and water variation.
- Pests and diseases increased as a result of the continuous cropping and the killing of predators and frogs by pesticides.
- Farmers sold cattle, as no they were longer needed for ploughing and manures.
- Mechanised rice mills displaced groups of women who used to thresh and mill the rice.
- Harvest teams replaced the communal *banjar* activities at harvest.
- As the new rice could not be stored for long periods (it had a thinner, looser husk and softer kernel), it had to be sold immediately after harvest when the prices were lowest. This meant men received large sums of cash, and the women could no longer plan for the year's food security by monitoring the rice barn. 'Wisdom lies in keeping the family's capital in the rice barn, where they can regulate and dispense it, rather than in the form of risky, hard-to-manage cash lump sums.'
- The *subak* organizations, once in complete control, lost many decisions to higher level institutions – now the government decides cropping patterns, planting dates and irrigation investments.
- The *subak* also organized redistribution through local religious and ritual culture, as the better off were expected to give more goods and services to community ceremonies.
- Reduced labour and employment in rice cultivation forced rural people to seek work elsewhere.

Source: Poffenberger and Zurbuchen, 1980

their territory. They have a complex grazing rotation system in which they move among eight different forage regimes. This can mean that some land is free of people and animals for long periods, which allows it to be preserved from overuse. All members of the community have access to communal land. But this access is not uncontrolled: certain areas and resources are protected by rights and obligations for individuals, clans and local groups. In the past, the customary rules and institutions had been effective in both maximizing production and conserving resources. The Barabaig, like many people who live in variable environments, have a tradition of respect for the land they rely on for their survival. Their elders recently said 'We value and respect the land. We want to preserve it for all time' (in Paavo, 1989).

But in order for wheat to be grown on the Basotu Plain, about 40,000ha of land was taken from the Barabaig. This was their most fertile prime grazing land. Some of them were forcibly removed and their homes burned. They were prevented from following traditional routes across the farms to reach pasture, water or salt resources. Many of their sacred graves were ploughed up and are no longer recognizable. There are also ecological problems, as the soil is left bare soon after the July harvest until the time of planting in February. This makes the soil susceptible to rain-induced erosion, and deep gullies have been created and the sacred Lake Basotu is being silted up.

Although the farms cover only 12 per cent of the total land area of the district, the loss of this area is crucial for pastoralist production (Lane and Pretty, 1990). By losing access to these fertile areas, the whole rotational grazing system has been disrupted, so reducing the pastoral productive capacity beyond the direct impact of the wheat farms. This loss has resulted in a drastic reduction of livestock numbers and a decline in production which the Barabaig say has caused them 'great suffering' (in Paavo, 1989).

Part of the problem is that outsiders misunderstand pastoralists and their production systems. Rangeland is common land to the Barabaig and individual herders move about in response to their assessments of range productivity or social needs. People who fail to understand this can be misled into thinking land is vacant or poorly managed by the pastoralists, so justifying their dispossession. One study of Canadian aid to Tanzania said: 'The project has many of the characteristics of a frontier development effort. Traditional pastoralists … are being displaced and absorbed into the project as labourers. Previously idle land is being brought under cultivation' (Young, 1983).

From the viewpoint of the farms, wheat production is financially profitable. A project evaluation conducted in 1980 arrived at a benefit/cost ratio of 1.59. The return to the capital of nearly 40 per cent also indicated that it was a 'very profitable investment for the Tanzanian economy' (Stone, 1982). But if the wider social and environmental impacts are accounted for, then the picture changes dramatically. The costs actually far exceed the benefits, and there would appear to be many better ways to use aid and scarce foreign exchange. As one economic assessment put it: 'The results of this study indicate that wheat production on the Hanang farms is profitable from the viewpoint of the farms… However, from the standpoint of contributions to, and resources used within, the Tanzanian economy the Project is shown to be uneconomic. In strict economic terms, the costs have exceeded the benefits' (Prairie Horizons Ltd, 1986). The financial resources spent developing a high input system in a remote and dryland region would have been more efficiently used for buying wheat on the world market.

Social change in India

Despite a wealth of studies on the impact of modern agricultural technology on the rural economy in India, there is no clear consensus as to whether labour opportunities for men and/or women have increased or decreased (Palmer, 1981; Agarwal, 1985; Chand et al, 1985; Whitehead, 1985; Sardamon, 1991; Chaudhri, 1992; Kaul Shah, 1993).

One recent study is now widely cited as evidence that the Green Revolution can lead to large, across-the-board gains in income, nutrition and standard of living for small- and large-scale farmers, and even for the landless poor (Hazell and Ramasamy, 1991). In North Arcot, Tamil Nadu, between 1974 and 1984, regional paddy output increased by 57 per cent, and this growth has had significant economic impact on the region's villages and towns. In addition to an increase in the wage rate, the distribution of income improved and absolute poverty declined. Small paddy farmers and landless labourers, who were initially among the poorest households, gained the largest proportional increases in family income, virtually doubling their real income during the decade. Non-paddy farmers and non-agricultural households increased their real family incomes by 20–50 per cent. As the authors put it: 'none of the predictions of the critics – that smaller farmers would be either unaffected or made worse off by the green revolution and that unnecessary mechanization would significantly reduce rural employment, thus worsening absolute poverty – came true'.

There is, however, considerable evidence that large-scale technological innovations tend to be followed by mechanization of some women's work (Whitehead, 1985; Palmer, 1981; Billings and Singh, 1970). This change displaces landless women workers and many of the tasks become 'male'. But there is also evidence to indicate that the demand for female agricultural labour can increase as a result of modernization (Agarwal, 1984, 1985; Chand et al, 1985).

One feature common to most studies on the impact of agricultural modernization is that they focus solely on employment, production and income distribution. Very few have considered the wider changes in livelihood strategies and the quality of life (Kaul Shah, 1993). But the introduction of technologies does not necessarily have to lead to social disruption. Where external institutions work closely with local people, then these new technologies can lead to improved welfare for men and women. A recent review of the activities of AKRSP in Gujarat has shown that since the introduction of modern varieties, fertilizers and plant protection measures, coupled with soil and water conservation measures organized on a watershed management basis, incomes of all households have increased since 1986 as a result of intensification (Kaul Shah, 1993). Rising agricultural productivity has increased the demand for local labour and so increased the opportunities for local work. This has made an enormous difference to the quality of people's lives. Both men and

Table 1.9 *Changes in livelihoods of men and women of Samarpasa village, Bharuch District, Gujarat, following the adoption of modern varieties, some fertilizers, and soil and water conservation measures as part of a participatory watershed management supported by the Aga Khan Rural Support Programme*

Criteria	*Before programme (1987)*	*After programme (1992)*
No. households migrating to Surat for 2–10 months of every year	42	6
No. women migrating without men	14	0
No. households not migrating	13	34
Agricultural wage labour (Rs/day)		
men	2	13–15
women	3	13–15
Number of village children in school	8	56
Regularity of full meals during summer	1 per 3 days	2 per day
Vegetable consumption	rainy season only	every day
No. bullock carts owned	0	19
Sources of livelihoods:		
agriculture	20%	60%
migrating labour	80%	20%
non-farm income/employment in village	0	20%
Women's involvement in decisions on purchase of vegetable seeds, milch animals tree saplings, clothing	none	regular
Ownership of clothing by women in landless and poorest group	1 set	3 sets

Source: Kaul Shah, 1993

women have experienced an increase in workload on their own farms, but it is the qualitative shifts in their livelihoods that people themselves say have been most significant (Table 1.9).

These qualitative changes were particularly important for women: their former work in labouring gangs in Surat was 'at the unbearable cost of insecurity, poor health, overwork, shame and loss of social respect' (Kaul Shah, 1993). The decrease in migration through substitution from local income-earning opportunities represents a significant improvement in welfare. Asked how they would describe being 'happy', women replied 'when we don't have to migrate to Surat and have enough to feed ourselves and our children'. This is despite the fact that wages are two to three times greater in Surat. Some of the most interesting changes recorded have been shifts in the work burden of men and women. Bullock carts are now used for gathering fuelwood and carting harvested rice from the fields, both formerly time consuming and heavy work for women. And where agricultural activities, such as weeding and paddy transplantation, were formerly segregated, they are now carried out by both women and men.

This is in fact a successful case of agricultural regeneration based on a judicial mix of local and external resources. Where it differs from the bulk of agricultural modernization efforts is in the formation of local institutions necessary for sustaining the changes. Once the migration cycle had been broken, people could stay in the village and were able to be fully involved in local decision making. These local institutions are a critical part of any effort for sustainable and self-reliant agriculture.

Summary

The pursuit of increased productivity and conserved natural resources in the course of rural modernization has produced benefits in the form of improved food production and some improvements in resource conservation. But these improvements look so good that it is easy to forget there have been losers as well as winners. All sectors of economies have been affected by modernization. The drive for agricultural efficiency has drastically cut the numbers of people engaged in agriculture in industrialized countries. External inputs of machines, fossil fuels, pesticides and fertilizers have displaced workers in Green Revolution lands. Rural cultures have been put under pressure, as more and more people have been forced to migrate in search of work. Local institutions, once strong, have become co-opted by the state or have simply withered away.

Many environmental and health impacts have increased in recent years; others have continued to persist despite all efforts to reduce them. These costs of environmental damage are growing, and are dispersed throughout many environments and sectors of national economies. A largely hidden cost of modern agriculture is the fossil fuel it must consume to keep outputs high. Modern agriculture has tended to substitute external energy sources for locally available ones. For each kilogramme of cereal from modernized high input conditions, 3–10MJ of energy are consumed in its production; but for each kilogramme of cereal from sustainable, low input farming, only 0.5–1MJ are consumed. A shift to low input systems could, therefore, have an impact on the process of global warming.

Pesticides have caused problems by inducing resistance in pests and damaging the health of farmers, farmworkers and consumers. The hazards are greater in developing countries and emerging evidence is producing a bleaker picture than appeared to be the case in the 1980s. According to the latest estimates from the WHO, a minimum of 3 million and perhaps as many as 25 million agricultural workers are poisoned each year, with perhaps 20,000 deaths. Studies in the Philippines, in particular, are showing how costly these problems are to national economies as well as to the affected individuals.

Despite the fact that indigenous systems of soil and water conservation are widespread, well adapted to local conditions, persist for long periods and are capable of supporting dense populations, soil erosion continues to be a problem throughout the world. To farmers, erosion reduces the biological productivity of soils and the capacity to sustain productivity into the future. Although soil erosion is clearly costly to economies as well as to farmers, it is difficult to calculate reliably the precise costs, though studies in Mali, Malawi and Java suggest that the costs to farmers are substantial, representing 3–14 per cent of gross agricultural product.

One surprising cause of soil erosion is bad soil conservation programmes. There are many examples throughout the world of impressive terracing and bunding disappearing when local people have not been involved in planning and implementation. Poor terracing results in worse erosion. The impact of these programmes has been to make many things worse. A failure to involve people in design and maintenance can create considerable long-term social impact, inducing widespread disenchantment among local people for all conservation projects that followed.

Biodiversity has fallen under modern agriculture. Farmers of traditional and low input agricultural systems have long favoured diversity on the farm, and it is only recently that fields monocropped to single species and varieties have become common. The introduction of modern varieties and breeds has almost always displaced traditional varieties and breeds. During the 20th century, some 75 per cent of the genetic diversity of agricultural crops has been lost. Only about 150 plant species are now cultivated, of which just three supply almost 60 per cent of calories derived from plants.

Agricultural modernization has helped to transform many rural communities in both industrialized and developing world countries. The loss of jobs, the further shift of economic opportunity away from women to men, the increasing specialization of livelihoods, the increasing concentration of land in the hands of wealthy villagers and urban investors, the growing gap between the well-off and the poor, and the co-option of village institutions for the purposes of the state, have all been features of this transformation. Cases are described of social change in Britain, Japan, the US, Mexico, Indonesia, Tanzania and India. In all of these the social costs have been substantial. Modern agriculture, though not the sole cause, has clearly been a contributor to these changes.

The Performance of Low External Input Technology in Agricultural Development: A Summary of Three Case Studies

Robert Tripp

Introduction

There is widespread agreement that strategies for agricultural sustainability should help limit dependence on external inputs. There are many reasons to support low external input farming, including a concern for environmental sustainability, increased attention to the conditions of resource-poor farmers, and the conviction that a better use of local resources in small-scale agriculture can improve farm productivity and innovation. The pursuit of low external input strategies requires access to a wide range of alternative techniques for farm management. These may be elaborations of traditional practices, introductions from other farming systems, or innovations devised by farmers or researchers. These alternatives are referred to here as low external input technology (LEIT). This paper summarizes a study that assesses the performance of LEIT in three project settings and draws implications for the role of LEIT in pro-poor agricultural development.

LEIT is the subject of some controversy. On one side, some dismiss it as a collection of hopelessly labour- and knowledge-intensive practices that have little relevance to agricultural development. On the other side, LEIT may be promoted as the key to small farm survival and the development of human and social capital in farming communities. This study tries to chart a course through such arguments by examining the utilization of LEIT in three important examples, attempting to draw conclusions that have wider relevance. The next section of the paper introduces the three projects on which the study is based. This is followed by an examination of the labour requirements of LEIT. The next section reviews concerns about knowledge-intensity, followed by a section examining the incentives for utilizing LEIT. The degree to which LEIT, once adopted by some farmers in a community,

can diffuse to others is the subject of the next section. This is followed by an examination of the hypothesis that local-level development of LEIT can make significant contributions to strengthening human and social capital. The paper concludes with some considerations regarding the effective promotion of LEIT.

The Study

The research reported here is based on three case studies (in Honduras, Kenya and Sri Lanka); a more complete description is available in Tripp (2005). The study sites were chosen following several criteria. The cases all examine relatively large projects that introduced examples of LEIT to many farming communities; this avoids possible biases related to the analysis of pilot project experiences. The cases were chosen from among well-managed LEIT projects to avoid confounding technology performance with problems in project management. In addition, the cases were chosen on the basis of evidence that some of the examples of LEIT had been taken up by a significant number of farmers. Finally, the research was organized to examine the experience of participating farmers (and their neighbours) at least five years after the termination of project activity. Assessment of technology adoption is often difficult in the immediate aftermath of a project, and the research was particularly interested in understanding further technology adaptation, diffusion, or abandonment, as well as seeking opportunities to examine the evolution of any project-related human and social capital. Table 2.1 presents a summary of the three cases.

The field research followed a similar pattern in the three sites, although differences in project organization were responsible for some variation in research protocols. Once the focus projects had been chosen, initial field visits were devoted to selecting appropriate sites, identifying participant communities whose experience seemed typical of the project, and finding comparable non-project communities to serve as controls. Researchers held informal discussions with farmers in the area and conducted small focus group exercises to gain a better appreciation of the important issues. Discussions were also held with local officials and others, and all relevant secondary data were examined. Researchers then selected random samples for a formal survey. In each case the samples included: (i) project participants, (ii) non-participants from the same community, (iii) farmers from nearby 'control' communities. The total sample sizes were 178 (Honduras), 128 (Kenya), and 210 (Sri Lanka). The researchers were present for all the interviews, although trained enumerators were used in Honduras and Sri Lanka. The interviews focused on general farming practices and conditions, not on the project per se. The interviews included details of current farming practices, those of the recent past and sources of information. The survey data were analysed and appropriate statistical tests were utilized. Lack of space in this paper precludes discussing detailed examples, but the reader should assume that any relationship described below (e.g. the correlation of a particular practice with a particular farmer characteristic) exhibits statistical significance (unless otherwise stated).

Table 2.1 *Summary of case studies*

Case	*Honduras*	*Kenya*	*Sri Lanka*
Project	NGO projects in central Honduras, beginning in late 1980s, for soil restoration on hillside farms. Each project included 30–35 villages.	National Soil and Water Conservation Programme, 1988–1998, worked in catchments of 2–300 contiguous households. Study done in Nyanza Province.	Sri Lanka Department of Agriculture and FAO supported 610 farmer field schools for IPM nationwide, 1995–2000. Study done in Southern Province.
Technology	In-row tillage, cover crops, physical barriers.	Small terraces, vegetative strips, unploughed strips, retention ditches.	Reduction of insecticide use; straw incorporation, single-nutrient fertilizers.
Participants	Open to all members of village; various levels of participation, from development of farmer leaders to occasional attendance at activities.	Majority of farmers in project villages signed up to participate, had farms surveyed by committee and discussed options.	Participation in farmer field school limited to about 20 farmers per village.
Labour input	Majority of in-row tillage and cover crop adopters say these save labour. Few who abandon technology cite labour input as a reason.	Strips more popular than physical structures, partly because of lower labour requirement. Adoption related to household labour availability.	Reducing insecticide lowers labour and cash investment, with no yield penalty. Straw incorporation requires labour but increases yields.
Technology utilization	Majority of participants continue using some LEIT. Utilization related to access to irrigation, area under cash crops; not related to farm size or slope of field.	Majority of participants establish some structures, but at low density. Greater use in high potential areas and on farms dependent on crop sale.	Those who work as farm labour less likely to participate and rely more heavily on insecticide. Rice is important income source.
Diffusion of technology	Most adopters share information with others. Little spread of technology in project villages; some (largely temporary) uptake in neighbouring villages.	Modest evidence of subsequent diffusion to neighbouring villages, but other projects promoting similar technology.	Little evidence of spread of IPM message to other farmers, despite enthusiasm of participants.
Further group activities	Participants and adopters belong to more groups, but no permanent organizations emerged from project.	Most catchment committees ceased activities after project completion. Various other projects draw on former participants.	Few groups survive after project; continued activity depends on extension or other project support.

The Honduras case examines the experience of several related NGO projects that promoted sustainable hillside farming, with particular attention to methods for soil fertility enhancement and soil and water conservation. The projects followed earlier successful experience elsewhere in Central America (Bunch, 2002) where participating farmers were motivated to experiment with new techniques and to build on recognizable success rather than rely on subsidies. The study revisits two of the areas in central Honduras where the projects took place. These are areas where previous slash-and-burn agriculture has evolved to permanent cropping on increasingly eroded hillside plots; farmers plant twice a year, with maize as the principle first season crop, followed by beans in the second season. Vegetables are the most important cash crop. The study examines experiences with techniques such as in-row tillage and the use of cover crops.

The Kenya case focuses on the National Soil and Water Conservation Programme, which featured a catchment approach where communities were encouraged to learn about and establish soil and water conservation techniques (Pretty et al, 1995). Elected local catchment committees served as major actors in the project. The programme was active from 1988 to 1998 and was national in scope. The study examines the aftermath in a set of communities in high- and low-potential areas of Nyanza Province, western Kenya. The principal subsistence crop is maize, but beans, banana, groundnut, sweet potato and sorghum are also grown. Maize and groundnuts are the principal cash crops. Farmers in the high-potential area are able to plant in both the long and short rains, but those in the low-potential area rely only on the long rains.

The Sri Lanka case examines an example of farmer field schools (FFS) for introducing Integrated Pest Management (IPM) and other crop management techniques in rice (Pontius et al, 2002). The Sri Lanka programme was managed by the Department of Agriculture, with assistance from the Food and Agriculture Organization (FAO). The study was conducted in communities in Southern Province, among farmers with access to irrigated paddy land. These farmers are generally able to plant two rice crops a year and this is a major source of income, as well as contributing to household subsistence. Most farmers also have at least a few tree crops and a minority have access to an upland field. The FFS concentrated on helping farmers lower the use of pesticides, particularly early in the season. It also supported the incorporation (rather than burning) of rice straw and promoted more rational fertilizer management through single nutrient fertilizers, rather than blends that had previously been promoted.

In each of the three cases there was clear evidence of the utility and continued relevance of various examples of LEIT introduced in the original projects. In Honduras, more than half of the participating farmers continued to use in-row tillage on part of their fields. (The technique involves planting on the contour and hoeing only within the row, in order to promote the formation of mini-terraces.) About one-fifth of the participants were using a green manure crop with their maize and about one-third had established some kind of live barrier for soil conservation. In Kenya, more than half of the project participants surveyed implemented at least one soil and water conservation structure during, or shortly after, the catchment project; the most common technologies were grass strips or unploughed strips. In Sri Lanka, the FFS participants made only one-third as many insecticide applications on their rice compared to other farmers, and there was also evidence that they tended to be further ahead in several aspects of soil fertility management such as the adoption of straw incorporation and the rational management of purchased fertilizers.

Given that the three case studies were focused on projects specifically chosen because of initial evidence of wide coverage, good management and relevant technology, it is not too surprising to find that there is still widespread utilization of LEIT five or more years after project activities were completed. However, the reason for selecting such cases was not merely to document continued technology use but rather to examine differences in utilization among farmers, the extent to which the technologies were subject to autonomous adaptation and diffusion, and their possible contributions to strengthening human and social capital.

Labour

Perhaps the most frequent criticism of LEIT is that it is labour intensive. Labour is a major constraint in smallholder farming and there are many instances where farmers show little interest in a technology because of its excessive demands on labour. The rejection of some types of LEIT because of high labour requirements is well known; the very limited success of alley cropping in Africa is but one example (Carter, 1995). Such cases are sometimes used to characterize LEIT more broadly, but we need to look more carefully at how labour requirements determine the acceptability of a technology. There are many examples where farmers are willing to invest additional labour if the payoffs are adequate. In addition, there is good evidence that the timing of labour demands may be as important as the absolute amount. There are also important questions, particularly relevant to LEIT, regarding whether the major labour investment is for learning and establishing the technique, or is required for its repeated performance. Pretty (1995) sees the initial investments as part of the 'transition costs' required to shift from conventional to more sustainable agriculture. Finally, once farmers gain experience with a new technique they are often able to manage it more efficiently than when they were first introduced to it.

Thus the implications of additional labour demands for the acceptability of a new technology are related to the flexibility available in the farming system, farmers' incentives to adopt new techniques, and opportunities to learn and adjust. The experience of the case studies demonstrates that simply characterizing LEIT as labour intensive overlooks these determinants. For example, the time that FFS farmers in Sri Lanka spent in learning about pest management in irrigated rice enabled them to permanently reduce their time and cash investments in insecticide application. This involved no additional control practices and no loss of yield, a win–win result. A more complex case involves in-row tillage in Honduras; it requires some extra initial labour investment but most farmers say that once established it makes weed control easier. A number of farmers tried the system and then abandoned it, but few of these mentioned labour requirements as a problem. Nevertheless, labour remains a factor in the diffusion of many types of LEIT. More Kenyan farmers established soil conservation measures with lower labour requirements (such as unploughed strips) rather than labour-demanding techniques such as terracing, and attempts to introduce FFS participants in Sri Lanka to green manures were unsuccessful, partly because of the labour implications.

A factor that further complicates the analysis of so-called labour-intensive technology is the fact that a considerable proportion of the labour used in even very small farms is hired. Where labour is a purchased input, the definition of low external input technologies becomes problematic. In Honduras, a sub-sample of farmers estimated the labour implications of establishing in-row tillage, revealing that half of the labour for this task was hired. In Sri Lanka, 70 per cent of the farmers hired labour for spraying insecticide and 64 per cent hired labour for planting, even though the average farm size is barely 1ha. Similarly, more than 60 per cent of the farmers in the Kenya study hired labour for weeding. A common defence of LEIT is that conventional technologies relying on purchased inputs favour those with cash resources, but as small farms come to depend increasingly on hired labour this distinction becomes less relevant. The notion that LEIT necessarily favours family labour on small, self-sufficient farms needs to be re-examined.

Labour-generating LEIT can reduce seasonal or permanent migration by offering local employment, but we need to understand whether people are working on their own, or others', farms. In Niger, for instance, the introduction of planting pits (a labour-intensive technique for building soil fertility and moisture conservation) has helped rehabilitate degraded land and improve yields (Hassane et al, 2000). The success has contributed to an emerging land market, but the purchasers are concentrated among a rural elite who are able to hire labour to establish the planting pits.

Thus various types of LEIT (like conventional technology) exhibit a wide range of labour profiles and a simple characterization of labour intensity masks more important considerations of flexibility, adaptation and incentives. Although LEIT may substitute labour for purchased chemicals or fertilizers, the labour may itself be an external input; differences in the ability to purchase that input may have implications for rural equity that are as important as differential access to other farm inputs.

Information

Technologies have different information characteristics (and hence make different demands on farmers to acquire that information and take control of it as knowledge). LEIT is often characterized as being information- or knowledge intensive, but this generalization needs to be disaggregated. In a review of low external input strategies, Lockeretz (1991) points out that we need to know: if such technologies are information intensive solely to develop or also to adopt; if the latter, whether the additional information needs to be acquired at only one time or whether it needs to be continually sought and updated; and whether the acquisition of the additional information requires only an investment of time or also implies new skills. It is difficult to argue that LEIT can be distinguished from conventional technology with respect to information intensity, especially with the demise of subsidized input packages. Byerlee (1998) believes that farming in industrialized countries and in Green Revolution areas in the South will have to pass from the stage where knowledge is 'embedded' in the inputs provided to farmers to a stage where information itself becomes a more important element. The provision of information will have to shift from general area-based recommendations (e.g. for fertilizer use) towards qualitative season- and site-specific advice, as exemplified by the rise of precision farming.

The case study examples of LEIT offer a range of examples of information requirements. Lowering insecticide use in Sri Lanka is a straightforward action, but it appears to require a fairly significant investment in learning about pest ecology and gaining confidence in the efficacy of natural pest control processes. The logic and implementation of grass strips in Kenya seems fairly straightforward, and farmers are able to make adaptations once the strips are established. In-row tillage in Honduras involves a process of gradual establishment and adaptation over several seasons.

Who Utilizes LEIT?

Both the information and labour requirements of alternative technologies must be considered in light of the incentives for investment. Farmers will make an effort to acquire new information (or invest in additional labour) when it yields a reasonable return. This helps explain why the general pattern of utilization of LEIT in the case studies is surprisingly similar to that of conventional technology. LEIT tends to be taken up by farmers who have greater commercial farming opportunities.

In the Kenyan case, uptake of conservation practices was much greater in the high potential area, where agriculture made a more important contribution to livelihoods. Users of the conservation practices have both larger farms and more cattle, although the relation is not statistically significant. In the higher rainfall zone in the Kenya study, those who established conservation structures on their farms earned a higher proportion of their incomes from crop sales. Those Honduran farmers with greater areas of cash crops and access to irrigation were significantly more likely to utilize LEIT, and the majority of instances of in-row tillage were for vegetables rather than basic grain crops. In Sri Lanka, on the other hand, the range in farm size is quite narrow and there is no correlation between rice area (or commercial rice sale) and insect control practices. On the other hand, it may be argued that the FFS addressed a rural elite (those with irrigated land), and rice sales contributed an average of 43 per cent of cash income for farmers in the sample.

There is also some evidence that LEIT allowed participants to expand their commercial farming. This is particularly true in Honduras, where it appears that specific practices such as in-row tillage (as well as the experience of participating in local technology testing and generation) were a stimulus for some farmers to begin commercial vegetable cultivation. In the high potential zone in Kenya, the option of growing grass strips for erosion control was made more attractive because of a concomitant promotion of zero grazing; farmers could harvest the Napier grass for their own cattle or sell it to neighbours.

The limited literature on the adoption of LEIT tends to reach similar conclusions. The use of a cover crop in northern Honduras was associated with farmers who grow larger amounts of maize and are more commercially oriented (Neill and Lee, 2001). A study of farming practices in an area of western Kenya showed that wealthier households are more likely to use low-input soil management techniques (fallows, compost, terraces) as well as external inputs (hybrid maize, inorganic fertilizer) (Crowley and Carter, 2000). The initial experience with the System of Rice Intensification (SRI) in Madagascar indicates that adopters are more likely to be surplus rather than deficit rice producers, with more land and often with better off-farm sources of income (Moser and Barrett, 2003).

The issue of off-farm income is important. Off-farm opportunities can provide extra cash to invest in agriculture or may offer alternatives to a moribund agricultural economy. In the high potential zone in Kenya, there was a negative correlation between income from business or petty trade and the uptake of conservation technologies. In Sri Lanka, in contrast, farmers who earned a higher proportion of their incomes from salaries or trade were as likely to be interested in IPM as those whose income was predominantly from agriculture. Possible explanations for the difference between the cases include the feasibility of balancing the various income-generating activities (e.g. petty trade in the Kenya case may keep the farmer away from the field) and perceptions of the profitability of investing in agriculture.

However, when a household's off-farm income opportunities are confined to casual labour there is less room for manoeuvre. In Honduras, most farmers were engaged in some off-farm labour, but those farmers in the lowest resource wealth category had the highest dependence on off-farm income and the lowest use of LEIT (or mineral fertilizer). In Sri Lanka, although there was fairly broad interest in the FFS, those farmers who also worked as casual labour were significantly less likely to participate (and used more insecticide than anyone else). Crowley and Carter (2000) describe the downward spiral of unskilled rural migrants from western Kenya who have too little time or cash to invest in the improvement of their own farms and end up working for others or migrating in search of employment.

Such households are unlikely to be able to take full advantage of LEIT programmes.

Diffusion of LEIT

There are hopes that LEIT may diffuse fairly rapidly to other farmers. If a technology is a product of local innovation or adaptation, it may find an understanding audience among neighbouring farmers, and if it relies on local resources it may be more straightforward to adopt. However, the case studies do not support these hopes for spontaneous diffusion. Although most of the participants in the case study projects were enthusiastic about their experiences and reported describing ideas and concepts they had learned to other farmers, there was only modest evidence that non-participants learned about particular techniques from project farmers. In Honduras, there was little adoption of in-row tillage and cover crops by non-participants, although about one-quarter tried out the technologies. The majority who tried the techniques learned about them from other projects, although some also reported learning from other farmers. In Kenya, farmers in some neighbouring communities established soil conservation techniques a few years after the project; the proximity of the project community certainly was important, although there are various other projects promoting these techniques in Kenya. In Sri Lanka, there was no evidence that FFS farmers played any significant role in convincing their neighbours to reduce insecticide use. It was more common that neighbour farmers had remembered (and acted upon) information from the project participants about soil fertility management than about pest management.

The lack of diffusion of LEIT technologies and principles from these well-managed and relatively successful projects must be taken into account when considering future strategies for the promotion of LEIT. Farmers require a certain amount of hands-on experience before they are motivated to utilize many of these techniques, although there is considerable variation. In some cases (e.g. grass strips or straw incorporation) the techniques are quite visible to neighbouring farmers, who are capable of copying the ideas with a minimum of experience. In other cases (e.g. in-row tillage) farmers need a period to learn and experiment with the technique and the experience is more difficult to communicate. And in cases where complex principles are the basis for a change in practice (e.g. agroecological analysis and the rationale for IPM) farmers may find it particularly challenging to articulate what they have learned to their neighbours. The lack of diffusion of the IPM message for irrigated rice, despite the success of FFS in Asia, is a particular concern (Tripp et al, forthcoming).

LEIT is often seen as an important shift in attitude towards farming rather than merely a set of innovations. If the uptake of LEIT involves a change in the perception of farm management, we would expect that those farmers who utilized one type of LEIT would be more likely to lower their use of external inputs in general. This does not seem to be the case, however. Honduran farmers who use in-row tillage and Kenyan farmers who establish conservation structures are both more likely to use fertilizer on their food crops. In these cases, the LEIT provides an environment in which a profitable fertilizer response is more assured. These examples illustrate that there is no necessary connection between the use of one type of LEIT and a general reduction in external inputs. In most cases, farmers make decisions about various crop management technologies independently and pragmatically, without reference to any overarching philosophy regarding external inputs. In addition, farming systems evolve and require the consideration of new management practices. The success of the LEIT project in Honduras is one of the factors that motivated some farmers to begin commercial vegetable production and this has led to a considerable increase in the use of pesticides (and there is no indication that vegetable growers employing in-row tillage use less pesticide than their neighbours who use conventional tillage).

This is not to say that farmers are unaware of environmental concerns or that the LEIT projects were not successful in helping encourage farmers to consider the importance of resource conservation. Rice farmers in Sri Lanka were anxious to extend what they had learned about IPM to vegetables, but had not been able to do so. In some cases those farmers credited environmental concerns for their interest in IPM, and FFS participants were much more likely than the non-participants to cite environmental rather than economic reasons for their choice of practices, but there was no evidence that such rationale took precedence over economic factors in decisions about technology use.

Human and Social Capital

Because LEIT utilizes local resources, is often developed through adaptive experimentation, and may be introduced through processes of social learning, it is reasonable to expect that it can make a greater contribution to the development of individual farmers' skills and broader community capacities than the introduction of conventional technology. LEIT projects often make a conscientious effort to promote these goals of developing human and social capital. The project in Honduras put particular emphasis on farmer experimentation and support to farmer-extensionists, following a model developed earlier (Bunch, 1982). Organization of conservation work in the Kenya case was guided by an elected committee, and the FFS approach used in Sri Lanka is well known as an effective application of social learning techniques.

In many instances, the technology introduced by the projects led to subsequent adaptation. In Honduras, about one-fifth of the participants who established in-row tillage made some type of modification subsequent to the initial adoption. Similarly, about one-third of the Kenyan farmers who established a conservation structure made further adjustments, such as combining structures or altering the width or management of vegetative strips.

It is more difficult to assess changes in farmers capacities for experimentation (Sumberg and Okali, 1997). The strongest evidence is from Honduras, where the project put particular emphasis on developing experimental skills. About one-fifth of the participants reported at least one experiment carried out subsequent to the project. In addition, a higher proportion of farmers who utilized LEIT reported trying alternative pest control techniques in maize (although they used no less chemical pesticides than other farmers). In the other two cases there was much less evidence of farmer experimentation. Projects that emphasize simple field experimentation can stimulate farmers to continue with their own investigations, but the case study examples do not support the view that LEIT projects, on their own, can set off a burst of local innovation. The comparison between FFS and local agricultural research committees presented by Braun et al (2000) emphasizes that the development of experimental capacities often requires a more long-term approach.

Because many LEIT projects feature group methods there is an expectation that successful experiences will lead to further organizational growth and innovation (e.g. Pretty and Ward, 2001). However, there was very little evidence that participation in an LEIT project was sufficient to maintain the original groups formed for the projects or to lead to further organizational development. In Honduras, farmers who participated in the project belonged to more organizations, but the project did not lead to any further group initiatives. On the other hand, the satisfaction some project participants experienced in acquiring useful technology may have encouraged their subsequent participation in other organizations. The density of rural organization in Kenya is the highest of the three cases, and although some of the catchment project participants went on to participate in other activities it is difficult to attribute this to the project itself. In only one site did part of a catchment committee remain together for further activities. In Sri Lanka, the FFS functioned for a season and then disbanded; the only exception was one case in which another extension activity (in seed production) drew on the members of a previous FFS.

LEIT projects are established in communities where social networks are already in place. If the projects are competently managed, they may contribute to further group-led initiatives. But the idea that a technology generation project has a high probability of leading to further, spontaneous group action is erroneous. Community organizations develop for various reasons, but permanent, autonomous capacity requires particular incentives. The high density of donor projects in certain areas can contribute to an image of organizational growth, as a group from one project is inherited by a successor project. But significant organizational development requires adequate incentives and local commitment, and often depends crucially on outside resources as well. A community in Honduras that served as an interesting contrast to the two principal project areas of the study provides a good example. The community demonstrated a very high uptake of LEIT and exhibited excellent local organization. But pre-project activity (including interventions from several external individuals and agencies) had already led to the development of a producers' cooperative. The community's location close to markets, its strong leaders, and opportunities for producing organic coffee all contributed to further success and particular interest in LEIT. The project played an important role in supporting this activity, but we can expect such a confluence of favourable circumstances in only a minority of cases.

The conclusion that the projects did not make the contributions to human and social capital that some LEIT advocates envision should not, of course, be taken as the final word on the subject. Identifying changes in individual or organizational capacity is not straightforward, and more innovative research methods may be developed to investigate this issue. But at this point we should be sceptical of any claims made on the basis of anecdotal evidence, and descriptions of project merry-go-rounds should not be taken as demonstrations of sustainable local capacity. In addition, just as the distributive implications of the technology require investigation, biases inherent in project strategies must be addressed. For instance, Gugerty and Kremer (2002) argue that some bottom-up rural development projects organized through groups may offer more opportunities for resource capture by an elite than do traditional top-down activities.

Effective promotion of LEIT

These results have implications for the way that LEIT is promoted. First, it is necessary to address the fact that LEIT does not necessarily reach the poorest farming households. A cogent criticism of some of the early support for the Green Revolution focused on the unreasonable expectation that technology could effectively redress inequalities in access to resources. The seed-fertilizer technology did not do this, and neither does LEIT. Place et al (2002, p281) conclude that natural resource management technologies, 'like agricultural technologies more generally, fail to be adopted by women farmers and poor farmers at the same rate as male farmers who enjoy greater wealth, education and socio-economic power'. Careful targeting and extra resources to include the poor in project activities may help redress these imbalances, but such strategies do not obviate the need for a much more realistic assessment of rural livelihoods. There are many so-called farming households that depend only marginally on agricultural activities. Their plight deserves particular attention, and solutions may include political reform that provides more equitable resource distribution, development of rural infrastructure and services, identification of alternative opportunities for rural labour and enterprise, and effective safety-net strategies for the vulnerable. Agricultural technology is only one part of the solution to persistent rural poverty, and technology projects must be linked with broader rural development strategies.

LEIT (or any other technology) has a much better chance of making an impact in situations where there is a dynamic agricultural economy. The case studies clearly showed that farmers engaged in commercial agriculture were more likely to take advantage of LEIT, and that those with fewer agricultural opportunities were in danger of neglecting farm stewardship, in some cases actually depending more heavily on external inputs such as pesticides. There are many instances where the use of LEIT is preferable to dependence on purchased inputs, and LEIT can make an indispensable contribution to farm management. The environmental motivations behind the promotion of LEIT remain valid, but these are rarely the principal factors in farmers' decision making. An approach that provides farmers with a wide range of opinion, information and options would seem, in the long run, a more productive strategy than one that insists on a fairly narrow ideological stance. It is possible to dismiss the notion that LEIT represents some kind of separate technological realm that automatically brings with it altered incentives and attitudes for farming but at the same time acknowledge the importance of developing a more thoughtful and varied use of local resources and knowledge. To insist that LEIT stands apart (as a minority of its practitioners do) is inefficient and unrealistic.

How can the lessons, techniques and motivations that characterize the best work in LEIT be promoted? The problem is often discussed in the context of the high per-participant costs of successful projects, and the usual policy prescription is scaling up. But given that any intensive local-level endeavour involves considerable start-up costs, and taking into account the fact that many LEIT projects are limited in breadth and focus, the search should be for economies of *scope* rather than *scale*. That is, the emphasis should be on establishing modalities through which farmers have access to a sustainable source of information and support for broad agricultural innovation rather than being subject to a series of projects, each one concentrating on a few specific technologies and often covering a relatively limited number of communities. Each project may have a separate focus and unique methodological preferences that militate against wider application. It should not be surprising that this strategy rarely results in the development of human and social capital.

Although it is fashionable to talk about offering farmers 'a basket of choices', the baskets developed by many LEIT projects are unacceptably limited. Attention to agricultural sustainability has highlighted the dangers of conventional agricultural technology simplifying farming systems and relying on a narrow range of options, lowering diversity and resilience. But efforts in LEIT are also subject to faddism and uniformity. Methodological uniformity is also a problem, as in the rush to organize farmer field schools for almost every subject imaginable. There is also a need to build further technical competence. NGOs can offer support for farmer organization, advocacy and local technology testing and adaptation, but something as complex as LEIT is not effectively promoted by well-meaning but inexperienced generalists.

The project approach to LEIT involves unrealistic assumptions about the possibilities of engineering local innovations and too little attention to building underlying capacity. There are very strong justifications for encouraging the emergence of viable groups, but these need to be based on interests that are broader than those of the usual LEIT project. Groups offer efficiencies in information transmission, form a basis for social learning and can help foster environmental consciousness. Much agricultural technology requires hands-on learning, and groups can facilitate access to these opportunities. In addition, group action is usually the most effective way for farmers to draw on external resources. Rather than serving as gatekeepers for access to agricultural research stations, projects should strive to make farmers understand that public research belongs to them and that a visit to an experiment station to seek attention to pressing problems is a right rather than a brokered privilege. Similarly, developing strong, broad-based farmer organizations that can exert pressure for more effective public extension may have higher payoffs than small-group activity in response to a brief donor project.

Current project-driven group formation related to LEIT is based on much too narrow a base, sometimes the development of a single technology. Project activity is an inefficient way of making up for deficiencies in basic education, information and markets. Farmer organizations will only be sustainable if they address major issues of concern to their members. Access to technology may be one of these, but it is unlikely that technology generation, on its own, will be the basis of a significant growth in viable organizations; it is less likely that specific technological issues (IPM, soil erosion control) would provide such a basis. Organizations need to offer as many advantages to farmers as possible in order to elicit commitment and offer opportunities for varying levels of participation. The transaction costs of group formation are considerable, and there is no sense in repeatedly making such investments for a series of short-term, isolated interests. The various initiatives with resources and rationales for group activities related to LEIT need to join forces in order to make a contribution to building sustainable local institutions.

Summary

LEIT includes an exceptionally wide array of technologies that challenge any attempt at generalization. Nevertheless, this study of three large and well-managed projects, combined with an extensive review of the literature, provides a basis from which to offer some fairly broad, but hopefully robust, conclusions. There are many instances where farmers are able to take advantage of LEIT. The technologies help farmers become more productive and conserve resources, and these techniques deserve further investment in research, development and promotion. However, the use of LEIT is much less widespread than some observers would hope. In addition, LEIT does not necessarily behave the way that either its supporters or sceptics maintain. On the one hand, LEIT is certainly not the rudimentary, hopelessly labour-demanding technology that some critics assume. On the other hand, despite its focus on self-sufficiency and its concern for marginal farming conditions, most LEIT is not particularly targeted to the poorer members of farming communities; its adoption exhibits patterns similar to those of conventional agricultural technology. In addition, the diffusion of the technology from farmer to farmer is often slow. Finally, despite the fact that LEIT is promoted as an approach to farming rather than as a particular technology, there are very few examples where LEIT efforts have served as a spark to ignite further individual innovation or group action.

These conclusions provide further evidence that there are no easy answers for improving the welfare of poor rural households. Although certain technologies are more appropriate than others for resource-poor farmers, time and resource constraints – as well as the demands and opportunities of off-farm income – limit the degree to which low-input farming can make important contributions to the poorest households. This implies a more realistic approach to policies for rural poverty reduction and full consideration of the role of non-agricultural opportunities. Where agriculture is important for household livelihoods, technology-specific, project-based strategies are inadequate. Much more attention is required for information provision and the development of broad-based organizations that allow farming households to gain access to the widest possible range of innovations.

Acknowledgements

The research summarized in this paper was managed by: Michael Richards, Laura Suazo (Honduras); Catherine Longley, Nelson Mango, Wilson Nindo, Caleb Mango (Kenya); Mahinda Wijeratne and V. Hiroshini Piyadasa (Sri Lanka). The research was supported by the UK Department for International Development (DFID), whose support is gratefully acknowledged. Initial summaries of the studies were presented at a workshop in London in June 2004, and the contributions of workshop participants helped to sharpen the analysis. The useful comments of two anonymous reviewers are also acknowledged.

The Politics of Food: An Introduction

Marianne Elisabeth Lien

In recent years, food has emerged as a political topic par excellence. Capable of connecting individual bodies to abstract communities and techno-scientific innovations to moral concerns, food has become a highly charged and contested field. Recent food scandals, such as the outbreak of BSE (bovine spongiform encephalopathy) and the public debates over GMOs (genetically modified organisms) have shattered the idea that 'food is food' as we always knew it, and have exposed fundamental dilemmas of modern food production related to risk and control. At the same time, food is increasingly involved in controversies at a transnational level, in relation to issues of access, dominance, trade and control in what is seen as a shared global environment. Such controversies have placed food at the forefront of political debates both within and between nationstates.

Not long ago, the term 'Politics of Food' would have drawn notice to a fairly specific set of problems within a particular set of arenas. The politics of food would have taken place within the domain of state bureaucracy. The term would have denoted a range of issues such as food security, social inequality, nutrition policy and agricultural policies. Focusing on the micro level, the politics of food could also involve the gendered and unequal distribution of food and labour within the household (Murcott, 1982; Charles and Kerr, 1988; Counihan, 1999). Going beyond the level of the state, the term might have applied to the study of unfair trade, the dominance of multinational corporations and food as a human right (Eide et al, 1984). Most importantly, the term 'politics of food' would have focused attention on the access to food at different levels of scale and the problems of matching access to needs. In other words, seeing food as a source of nutrients, and politics essentially as what political institutions did (or ought to have done), the *politics of food* would have been located where the two came together.

Since then, the field has been extended in novel directions. In light of current controversies, a purely institutional approach to food politics is, in itself, no longer capable of capturing the vast array of connections that relate to food production,

distribution and consumption. We do not argue here that institutional approaches to the politics of food are irrelevant, nor that the issues of need, access, nutrition policies and global inequalities are less important today than they were a generation ago (see Pottier, 1999; Hart, 2001). Rather, we argue that contemporary issues require that our notion of the politics of food is expanded to fields and arenas not traditionally thought of as 'political'. Accordingly, our aim is to draw attention to some of the less obvious ways in which food is politicized. Most contributions to this book are inspired by anthropological perspectives on food and eating, and many apply an ethnographic approach. Yet, this book is not strictly anthropological, as it draws on insights and methods that are central also to other disciplines in the humanities and social sciences, most notably linguistics, political science, history and sociology.

To indicate that the politics of food takes place both inside and outside the arenas normally designated as political is to draw attention to controversy, hegemony, resistance and conflicts of interest that underlie both the structuring of food choice and the structuring of public and media agendas. But it also implies drawing attention to how food itself has become a political object. These issues are elaborated in the introduction. But first, let us briefly recapitulate some events that have changed the way we think about the food we eat.

What Happened? Transformations of Substance and Scale

A notion of risk has been introduced. When in 1996 a UK laboratory demonstrated the suspected link between BSE in British cows and the rare and mortal brain disease in humans called vCJD (a variant of Creutzfeldt-Jakob Disease), the event provoked chain reactions all over the world. Apart from making headlines in most European newspapers and causing a worldwide ban on British beef, the event epitomizes what, in hindsight, may be seen as the emergence of both a new awareness of risk and an increased distrust in political institutions as key issues in public debates about food in Europe, and subsequently also in the US.[1] The case of BSE in Britain demonstrated for many that government officials could not be trusted (a picture of the then UK Minister of Agriculture feeding his daughter a beefburger to prove its safety was circulated widely across Europe). It also exposed how the beef industry, seeking to cut expenses, had used bovine meat in the production of feed for bovine animals, thus transgressing the rule that, until then, had largely remained unspoken, namely that herbivores should not be forced to feed on species of their own kind – a type of cannibalism. This practice might never have become public knowledge had it not been for the fact that temperatures used in feed production were turned down (another cost-cutting measure), thus allowing the prions causing BSE to migrate from contaminated carcasses to healthy cows and, in turn, across species boundaries to human consumers (Franklin, 1999). In this way, the case of BSE also became a vivid illustration of commercial greed, of inept food-safety authorities, untrustworthy politicians and a nature that, according to media coverage, had the ability to 'strike back'. Thus, in the case of BSE, the political implications of a food scandal have had significant and far-reaching consequences, even if the implications for human health are still being debated, as the number of people directly affected by vCJD is still relatively low (Zwanenberg and Millstone, 2003).

The BSE scandal came in the wake of other scandals, such as salmonella and dioxins in chicken, so that the 1990s may be seen to represent a historical watershed with regard to the way food is thought about, talked about and handled. Food is no longer simply a much-needed material resource; its purchase is now linked to the need for consumers to balance monetary concerns with issues of risk and distrust. What could previously be left to food safety authorities and nutrition expertise hit the headlines of the news media and became a topic of expert controversy and public debate. Where policy measures used to be dominant, a complex interplay of food producers, food control, state policies, news media and the public is now involved in defining food safety. As a result, 'what's for dinner?' has become an issue of considerable concern, demonstrated yet again in the most recent food scare about carcinogens in salmon sparked by a food safety report published in the US (see www.foodstandards.gov.uk/news/pressreleases/sciencesahiion). Food is politicized, not only as a commodity for consumption, but all the way into the kitchen and the dinner table, with implications for cooking and family care.

Genetic modification of food, which again hit the headlines in the 1990s, has meant that many of our most common foodstuffs can no longer be taken for granted. Since the emergence of GMOs on the food market, the material properties of food itself have become the subject of controversy. Some argue that genetic modification represents only a faster method of plant cultivation, and one with immediate benefits. Critics maintain that speed makes a difference, as it collapses qualitatively significant material changes into a time span of a few years that would previously only be noticeable over several generations. Such changes expose the malleability of edible substances, and force us to realize that the foods we eat are the result of human manipulation, often with unintended consequences. No longer trapped in a 'black box' of conventional (agri-) cultural practices (Latour, 1987), food is thus exposed as a hybrid phenomenon. As such, it immediately enters the battlefield of conflicting agendas and interests. In this way, the politics of food has come to be implicated in the very notion of food itself, what food is and what it should be.

Genetic engineering has implications far beyond its actual implementation. Even in Norway, where GMO foods are still marginal and essentially banned, public awareness of the options inherent in genetic engineering has opened the food debate toward new problem areas, and has thus politicized the very substance of food, even though our tomatoes are still more or less the same. In this way, the politics of food is no longer confined to policy making within the nation state, but closely connected to innovations and discourses that take place on the transnational arenas of science, technology and trade.

Food on Transnational Arenas

Food is increasingly involved in controversies at a transnational level. The global politics of food involves not only the unequal distribution of access and rigged producer markets, but also moral and political engagements in relation to what is seen by many as a single global environment (Franklin et al, 2000). In this way, the politics of food is also politics at a distance, as exemplified by consumer boycotts, internet petitions and other examples of global-environmental activism. Several factors constitute the background for this development. First, although the long-distance transport of food is far from new (cf. Pelto and Pelto, 1983; Mintz, 1985), the delocalization of food has become more significant during the last decades, leading to what some scholars refer to as the 'globalization of food and nutrition systems' (Sobal, 1999). Using the terminology of Held et al (1999) one may reasonably argue with regard to food that we have witnessed an increase both in the extensity of global networks, in the intensity and impact of global interconnectedness, and in the velocity of global flows. This implies that the potential impact of local events on distant affairs have become even more significant. This imbues some affluent consumers with a sense of responsibility for relations that are not only distant, but also extremely complex and hard to grasp, and thus brings world politics into the shopping cart. At the same time, as global consumers, we are vulnerable to shifts in practices, regulations and routines that take place in distant regions of the world. Negligence, fraud and adulteration represent sources of risk to most of us, even if they happen elsewhere, just as corporate decisions that are made in New York, or policy decisions made in Brussels, may have dramatic consequences for the access to food and livelihood in rural India.

This is just another way of saying that as food systems are globalized, food becomes entangled in complex webs of political significance. It does not, by itself, make food a political object, but it vastly increases the number of diverse interests, relations and regulatory frameworks that are enrolled as each food item makes its way from production through to consumption (Fine and Leopold, 1993). Hence, the potential for interests to diverge and come into conflict also rises exponentially, even if only a few of these conflicts ever surface on the political agenda of the public media.

In the case of food, therefore, its socio-political relations of production are always more significant than the food item itself might reveal. What appears to be a carrot or a piece of meat is indeed a product with a history and implications more complex and profound than most of us even want to think about. This gap between what we actually know about the food we eat and what we could potentially know (and even act upon), makes transparency a key issue. Thus, the politics of food is also a politics of silence and exposure, a quest for the power to control what will be declared, what will be the focus of public debate and what will remain unspoken (Nestlé, 2002). This issue has been in the forefront of the debate concerning GM food in Europe, where the issue of explicit and exhaustive labelling has brought European governments into conflict with the US. Transparency is also a key theme in the debate in the wake of the first diagnosis of BSE in a cow in the US in 2003 (cf. *The Guardian*, 12 January 2003; www.oie.int/eng/press/en_031224.htm).

The problem of safety and transparency is not new. It was the basis for the creation of regulatory systems for food control established as early as the 19th century. Yet, we argue that with more abstract relations[2] between producer and consumer, a weakening of expert authority (Beck, 1992) and frequent exposures of food 'scandals' in public media, consumers sense even more strongly the impossibility of being 'fully informed'. As a result of what is experienced by some as a 'knowledge deficit', the politicization of food is more than ever a selective process of choosing to highlight one particular issue out of myriad potential candidates. Since the list is almost endless, the question of which items to politicize becomes a political issue in itself.

At the same time, food is always locally embedded. The cultural, social and moral context for the provision and consumption of food is also a local context. Such local contexts filter which food-related issues are to surface on the public agenda, and provide a framework within which such issues are constructed, interpreted, discussed and solved. In other words, all novel developments, from the impact of foot-and-mouth disease (FMD) on the English countryside to new technologies of genetic engineering, are always understood in the light of relations and distinctions that are significant in relation to a local and familiar framework. Thus, the discovery of BSE in the Czech Republic resonated with the prominent ambivalence about East–West boundaries in the post-Soviet states, while the French campaign against GMO was absorbed in an anti-American, anti-globalization movement and expressed through promotion of French Roquefort. Similarly, the British debate about the 'foot-and-mouth' epidemic tapped into a pre-existing framework of urban consumer guilt about the greedy capitalist exploitation of the local countryside, while transnational anti-whaling campaigns draw upon Euro-American notions of individualism and family values to evoke sympathy for the whales. In this way, controversies that may appear at first to be part of a discourse that some scholars refer to as 'transcultural' (Milton, 1996, p170) turn out to be strongly embedded in values and distinctions that are, in fact, highly specific. Thus, in an era of so-called globalization, when it comes to food, the boundaries between local concerns and global affairs are not easily drawn.

Why Food?

Much of what has been said so far about transformed processes of production and globalized systems of provision could have been said about a whole range of material products, such as textiles, petroleum, hardwood, pharmaceuticals and more. Yet, several features make food a unique phenomenon, more profoundly absorbed in complex relations than any other product, and yet different from everything else. What is so special about food?

As a material substance with a crucial balance of nutrients and toxins, food has immediate biological implications. Unlike clothing, piercing, or body paint, food is literally transformed and becomes *part of* the human body. Thus, the saying 'you are what you eat', has several layers of meaning, from the symbolic to the material. But the absence of food has profound implications as well. The physiological need in humans to eat every day makes access to food a crucial issue, and has compelled human beings throughout history to develop social and technical systems of provision that aim to ensure stable food supplies through domestication, exploitation, reciprocity and trade. It also makes us vulnerable, weak and easy to control. In this way, food is entrenched in structures of subordination, governance and domination.

Second, as food and eating are routinized on an everyday basis, food becomes a convenient medium for the expression of social and ceremonial distinctions, and for naturalizing relations of community and hierarchy. As such, the symbolic meaning of food in any given context may be seen as sedimentation of historical structures of power and inequality that have been operating through generations (Bourdieu, 1979; Mintz, 1985). As a symbolic system of meaning, food is therefore both a structured and a structuring force.

Third, humanity's attempts to enhance bodily functions and abilities through scientific means have paved the way for what in the field of food is captured by the term 'nutritional science'. As nutrition has become one of the most significant fields of preventive medicine, it serves also as a structuring agent in relation to food choice. In this way, scientific nutrition advice may run contrary to agricultural interests (Kjærnes, 1993), food industry (Nestlé, 2002) and even national food and nutrition policies (Lien, 1990). In this way, connections between food and body also give rise to conflicts between policy interests, business and science.

The Legacy of Anthropology

As anthropologists have demonstrated since the inception of the discipline, food is a profound medium of reciprocity that marks and distinguishes persons and relations through acts of sharing, giving and receiving (Malinowski, 1922; Mauss, 1925). Add to this the significance of food in systems of classification (Leach, 1964; Douglas, 1966, 1975; Lévi-Strauss, 1970), the social organization of labour in food production (Richards, 1939; Evans-Pritchard, 1940), food in religious and healing rituals (Archetti, 1997), and the precarious interplay between the extraction of food resources and the environment (Rappaport, 1968), and we have a rough idea of the various ways in which food would make its way into holistically oriented anthropological monographs of the 20th century (for an overview, see Douglas, 1984; Murcott, 1988; Sutton, 2001). Food's importance as a social mediator, a cultural symbol and a natural resource is readily apparent in holistic studies of small-scale societies.

Yet, as anthropologists' attention shifted from small-scale exotic societies to post-industrial societies closer to 'home', the holistic approach has become more difficult to realize. At the same time, there has been a tendency toward analytical specialization through subfields since around the 1970s. Today, food is no longer an indispensable component of a social and cultural analysis. Rather, in more recent publications, food tends to be either the paramount topic of analysis, or hardly mentioned at all. Thus, the 'anthropology of food' has emerged as a distinct subdiscipline,[3] widely popular but often also somewhat detached from more general research issues. What we witness here is partly an attempt at cutting problems 'down to size' (such as 'food and gender', 'systems of provision', 'food production', 'food and risk', 'food consumption' and so on) in order to address urgent challenges in applied research, or to link food to topical concerns. However, as a result of such delineations, the complex entanglements that were the hallmark of more holistic anthropological accounts tend to be lost.

Furthermore, the way we choose to cut the problem down to size is often informed by the way we order and classify food generally, that is deeply entrenched in Western ways of thinking about and ordering the world. Certain Euro-American cultural distinctions have therefore – almost unnoticed – slipped into our theoretical apparatus and provided us with approaches to food that split apart dimensions of food that are, in fact, closely connected. Thus, broadly speaking, food is approached as either nature or culture, either production or consumption, either as an aspect of the private *or* the public domain. Although this is a common problem and difficult to escape, it is perhaps more problematic in the field of food than in other areas, because it often implies that we cut our analyses precisely at the most interesting junctions. As a result, the analytical possibilities inherent in the multiplicity of food, i.e. the analytical potential of food as a mediator between domains commonly set apart, is often lost.

What we need is not a return to meticulous accounts of villages as in the anthropological classics, but rather a re-evaluation of an underlying premise that has shaped the anthropological structure of inquiry: the fundamental assumption that relevant connections cannot be defined in advance, but emerge as a result of empirical research. This inductive approach lay at the heart of functionalist anthropology and went hand in hand with the holistic approach. Today, in an academic world already ordered by neat and sharp subcategories (risk, globalization, embodiment, etc.), a more holistic approach may seem impossible to achieve. Research projects must to be formulated in relation to culturally predefined domains, and food studies are no exception. Yet, I would suggest that precisely in this situation, more widespread intellectual disobedience in relation to the overarching categories would allow food studies to move a step forward. The degree of entanglement of a phenomenon can never be ascertained in advance, and this is especially the case in relation to food. In a world of global systems of provision, abrupt material transformations and complex layers of governance, most efforts at compartmentalizing food in accordance with predefined categories are bound to be too narrow. Malinowski claimed in 1922 that:

> An Ethnographer who sets out to study only religion, or only technology, or only social organisation cuts out an artificial field for inquiry, and he will be seriously handicapped in his work. (Malinowski, 1922, p11)

Malinwoski's advice to anthropologists in the early 1920s captures what could be seen as the most significant lesson to be learnt from anthropology in the field of food studies today: one who sets out to study food only as consumption, production, globalization, embodiment, nutrition, family life or economics is likely to be trapped by the same boundaries that structure the very field that she or he tries to illuminate. Fresh insight into contemporary dilemmas requires research that challenges such sectorial boundaries. I am proposing an approach to food which resists such preconceived distinctions and follows instead the connections that food allows humans to make. Just as Appadurai (1986) suggests we might study the 'social life of things', food may be followed through its various entanglements, across boundaries both legal and moral, beyond and between nations, bodies, persons and nutrients. If we do that, we will find that what appears as controversies about food often turns out to be controversies about something else.

Mary Douglas once said, referring to consumption more generally, that 'the essential function of [food] is its capacity to make sense' (Douglas and Isherwood, 1979, p40). I argue that the essential function of food is its capacity to make connections. Approached holistically, food effectively dissolves most preconceived distinctions between nature and culture, production and consumption, morals and markets, family and society, the individual and the collective, body and mind. At the same time, it remains a profound medium of reciprocity, constituting meaningful relationships at different levels and of different kinds. It is precisely through this capacity to make connections that food has become a highly charged political object.

To state that food is a political object is another way of drawing attention to the fact that many relations that are constituted by and through the medium of food are also power relations, and should be analysed as such. Our approach to power relations goes beyond, or even bypasses, a focus on the formal institutions of the state (Gledhill, 1994; Vincent, 2002). In light of the crisis of legitimacy characterizing political life in general, and the deregulation and liberalization currently affecting food in particular, a focus on policies, bureaucracies and politicians would simply be too narrow to grasp significant issues and changes. Politics, like food, is embedded in social practice, discourse, controversy and conventions that are not always labelled 'political'. Thus, our approach to the politics of food is based on the premise that 'action which contests existing power relations may take many forms', and that much of this is 'in constant danger of slipping from view, simply because of its everyday and inchoate quality' (Gledhill, 1994, p23). Drawing attention to some of the less obvious ways in which food is politicized, we seek to contribute to a more nuanced understanding of both politics and food.

Governmentality, Risk, Embodiment, Nature

What connections are illuminated through an empirical focus on food? Most issues below have been developed theoretically by other scholars and from other topical angles. They are included here because they are particularly relevant for analyses of contemporary power relations surrounding food.

One such connection is captured by the term governmentality (Foucault, 1991; Coveney, 2000) referring to the emergence in Europe of a concern for the governance of a complex of 'men and things' through a range of techniques for knowing about populations (statistical surveys, medicine, demography) and for managing populations through such knowledge. In the book *Food, Morals and Meaning*, John Coveney makes a powerful link between a Foucauldian concept of governmentality and the 20th-century discourse on food and nutrition, arguing convincingly that nutrition is:

> a government of food choice which situates the individuals within a field of knowledge for explicit objectives, and, at the same time, provides them with a way of constituting themselves as ethical subjects through a decipherment of their pleasures and fulfilments. (Coveney, 2000, p177)

Coveney's use of Foucault helps us to trace how food mediates relations between the state and the individual, or between the nation and 'its' human bodies. Most importantly, he demonstrates how governmentality in relation to food involves the socialization of family members as 'good' parents, 'good' children and 'good' citizens, and thus involves the construction of ethical subjects.

Another set of issues relevant to the study of food and social connections is captured by the recent emphasis on institutional reflexivity (Giddens, 1991), risk-society (Beck, 1992) and related terms like radical doubt, uncertainty and (lack of) trust. Although these descriptions of high modernity are somewhat eurocentric and hardly applicable on a global scale, they draw attention to a range of dilemmas that are strongly felt along the North Atlantic rim. Because they transcend the physical boundaries of the body, food and eating practices are highly sensitive to shifting configurations of risk and trust (Fine and Leopold, 1993). Furthermore, since what is harmful in food often escapes the senses (i.e. toxic substances cannot always be seen, smelled or tasted), trust in relation to food is abstract, involving social relations that are often distant, and often more imagined than real (Lien, 1997). Consequently, changing configurations in the relation between the state and its citizens, or between supplier and consumer, are likely to be expressed as uncertainty about food and risk. Similarly, as the case of BSE has shown, food scandals can bring about significant changes in the organization of safety regulations and systems of provision. In recent years, scientific authorities have been losing public trust. Although European countries differ greatly in this respect (Poppe and Kjærnes, 2003), there is a general trend in which science and experts no longer offer the sense of certitude they once did. One aspect of this 'post-enlightenment' turn is the transformed role of the media from that of being disseminators of expert knowledge to becoming virtual battlefields of conflicting expert claims. In this situation, the politics of food is also a 'politics of discourse' in which the power to set the public agenda, to frame the debate, and to silence opponents become a key resource. Such politics of discourse may be analysed as the strategic use of food metaphors, the distribution of blame and shame, and the role of the media in framing abstract risks in such a way that they are perceived as 'real' or relevant to ordinary consumers.

A third set of issues that emerge from the connections that food help us make relates to the sensory and experiential dimensions of food and eating. As an anchor of embodied experience, food often plays a key role in collective or individual acts of remembrance (cf. Karen Blixen's *Babette's Feast*, or Marcel Proust's account of 'La petite Madeleine'). David Sutton has explored these dimensions by drawing attention to the often ignored potential of food to evoke memory. In his book *Remembrance of Repasts* (Sutton, 2001), he makes a fine attempt to bridge the Cartesian dualism of mind and body by analysing food in a Greek village as both semiotics *and* embodied experience. Drawing on the works of Paul Connerton (1989) on commemoration and Thomas Csordas (1994) on embodiment, he demonstrates how worlds of experience and interpretation are contained in food. Here, we take this further, showing how eating as a commemorative act highlights the role of food in political conflicts regarding land claims and displacement of refugees. Food thus emerges as a material link that confirms and establishes, in a very sensual manner, the felt connections between a people and a place. Such connections reveal important nuances to the alleged ability of globalization to weaken ties of kinship and place (Eriksen, 2003). The fact that food politics is also body-politics has also been developed in other directions, through explorations of food and gender (Counihan and Kaplan, 1998; Counihan, 1999) and of food, body image and self-identity (Lupton, 1996).

Finally, a view of food as nature draws attention to the connections that are made between food and the natural environment, and between food and an idealized image of nature as opposed to culture and technology. Today, when science and technology can more than ever before refashion what we used to see as nature, the concept of nature appears to retain an even greater capacity to capture our imagination and to encapsulate notions of what is good, sound and true. Thus, even though the foods we consume are shaped, adjusted and manipulated by human intervention, references to nature abound in food advertising, culinary discourse and public debate (Lien, 1995, 1997). This obsession with nature affects the way we think about food both in relation to environments of production (e.g. organic farming methods), in relation to food products themselves (e.g. processed foods versus 'natural' foods), and in the way we envisage the way food shapes our body and health (e.g. popular 'Paleolithic' diets). We need to pay attention to a 'politics of nature' which, in contemporary discourse, goes beyond what is traditionally captured by the term environmentalism. As Macnaghten and Urry (1998) note, there is not one single nature, only a diversity of natures that are contested and constituted through a variety of social, cultural and political processes. When we envisage food and diets as more or less 'natural', or argue for schemes of production that are more (or less) sustainable or harmoniously adapted to our notions of nature, we latch on to these debates, and thus find ourselves in a field which is already highly charged with assumptions of a rather dubious kind. Bruno Latour (1987) offers a way out by suggesting a symmetrical approach in which nature and society are analysed on equal terms. In his analysis of modern practices of purification and translation between nature and culture (Latour, 1993), he provides us with a theoretical framework which is fruitful for understanding the hybrid nature of food, and its contemporary oscillation between the natural and cultural domains.

Thanks go to Keith Hart and Brigitte Nerlich for their careful comments and constructive criticism.

Notes

1 We do not argue that BSE in the only factor contributing to this awareness – several other food scandals played a part. Nor do we argue that food distrust was caused by the BSE event in a straightforward manner; in the UK such distrust had in fact been 'simmering' for years. What we argue is that the case of BSE was significant, both in bringing about political change and in serving as a model for exposing controversies in media, even in countries that remained uncontaminated by the disease itself. In this way, it represents a case in which, afterward, things were never quite the same.

2 Abstract relations refers both to the distance, socially, culturally and spatially, between production and consumption, and to the processes of abstraction that characterize the ways in which suppliers and consumers are made apparent to each other (through market surveys, sales statistics, and through the emphasis on brand name at the expense of structures of ownership and agency in food production, cf. Lien, 1997).

3 This is exemplified by the development of nutritional anthropology as a distinct subfield in the US. In Europe, we find similar developments toward compartmentalization under the heading 'anthropology of food'.

The System of Rice Intensification (SRI): A Challenge for Science, and an Opportunity for Farmer Empowerment Towards Sustainable Agriculture

Abha Mishra, Max Whitten, Jan Willem Ketelaar and V M Salokhe

Introduction

Rice is the dominant staple food crop throughout Asia and is an important source of carbohydrate and fibre globally. In Asia alone, more than 2 billion people obtain 60–70 per cent of their calories from rice (FAO, 2004); and global demand is expected to rise by 38 per cent above the current production within 30 years (Surridge, 2004). No doubt the Green Revolution helped many Asian countries achieve food sufficiency, but it also degraded the environment and threatened agricultural sustainability (Pretty, 2002). Competition for land due to urbanization, an impending water crisis (Wopereis et al, 1994; Barclay, 2004), declining soil fertility, and overuse and misuse of harmful agrochemicals pose threats to production. At the same time, current technologies are approaching their limits (Horie et al, 2005) and are no longer sufficient to meet increasing demands with relatively shrinking natural resources. These considerations have generated a number of novel rice production management techniques, some of them overlapping. These include alternate wetting and drying (AWD) (Belder et al, 2002), aerobic rice culture (Bouman and Tuong, 2001), integrated crop management (Balasubramanian et al, 2004), use of controlled-release of fertilizer (Shoji and Kanno, 1994) and, more recently, the System of Rice Intensification (SRI) (Stoop et al, 2002). SRI, among these 'alternative' options, is currently perhaps attracting the greatest interest, and certainly the most controversy. The article in *Nature* (Surridge, 2004) acknowledged SRI's growing popularity

Reprinted from Mishra A, Whitten M, Ketelaar J W and Salokhe V M. 2007. The System of Rice Intensification (SRI): A challenge for science, and an opportunity for farmer empowerment towards sustainable agriculture. *IJAS* 4(3), 193–212, Earthscan, London.

and presented a review on its current status, reporting statements for and against. The 'SRI' coordinating website, managed by The Cornell International Institute for Food, Agriculture and Development (http://ciifad.cornell.edu/sri) provides an overview of the set of management practices that define SRI and documents what is happening globally with SRI, mainly at farmer's field level.

Many small-scale SRI farmers are witnessing phenomena that are entirely novel within their lifelong experiences. Individual rice plant, grown from both traditional and 'Green Revolution' improved varieties, are seen to respond to SRI growing conditions with unexpected increased vigour in three major areas – roots, vegetative parts and grain yield. These responses, at the individual plant level, are real. It has been found that improved varieties respond positively, usually better than traditional varieties, but the latter also have given some remarkable increases in yield and profitability (Koma, 2002; Anthofer, 2004).

In many cases, farmers are claiming that the positive responses at the individual plant level have translated into higher crop yields while reducing key inputs, in particular, seeds, synthetic fertilizers and water. Controversy surrounds particular aspects of these lower input claims: some say labour demands have increased, e.g. for weeding; some say unsustainable levels of organic matter are required; some argue that crop yields have been unrealistically extrapolated from small experimental plots.

It would be simplistic to say that the enormous gains achieved in rice production by the Green Revolution technologies have been entirely due to the development and use of certain genotypes that respond favourably to high inputs of synthetic fertilizers. But, to the extent that these two elements fuelled the Green Revolution, it created a path dependency which has demanded continual genetic improvements to maintain production levels, let alone increased production from limited land. It is also acknowledged that the Green Revolution, by increasing dependency on external inputs and alien technology, reduced the opportunity and incentive for farmers to manage their natural resources and make their own crop management decisions. In essence, the Green Revolution had tended to disempower rice farmers.

Biotechnology favours the notion that 'the solution lies in the seed' and gives renewed enthusiasm to supporters of the Green Revolution philosophy. It is not surprising that some of the Green Revolution scientists have dismissed SRI as an unnecessary distraction (Sheehy et al, 2004; Sinclair and Cassman, 2004; McDonald et al, 2006). Sinclair (2004) described SRI reports as an 'Agronomic UFO' (unidentified field observation); while Sheehy et al (2005) labelled SRI 'a flawed idea and nonsense curiosity'. These characterizations say more about the emotions SRI has generated than about scientific reasoning or investigation. The reality is that millions of smallholder rice farmers in developing countries are experiencing a wide gap between potential and actual farm yield (Papademetriou et al, 2000; Stoop and Kassam, 2005; McDonald et al, 2006). The gap has become manifest at a time when scientists are claiming that rice yield is approaching a limit.

This gap and current economic exigencies should be providing an incentive for farmers to explore the potential of novel options. Why is SRI attracting the lion's share of attention? SRI offers a set of management practices that farmers can evaluate, adapt and then adopt to meet their own local requirements, rather than adopt some preset package of practices. Moreover, it relies minimally on external inputs and maximally on farmers acquiring and using new knowledge. The FAO Community IPM programme in Asia (www.communityipm.org/) demonstrated the ability and willingness of rice farmers to become experts at growing a healthy crop. For example, these empowered farmers learned the merits of conservation biological control – exploiting local biodiversity to manage pests instead of the unnecessary use of synthetic pesticides – a process labelled 'informed non-intervention'(Gallagher et al, 2005). SRI provides farmers with a new set of options that create considerable scope for 'informed intervention' (Stoop et al, 2002); for example, careful, rapid and shallow transplanting of younger seedlings, that are more widely spaced and use less water. These interventions are counter-intuitive, given current practices and beliefs, and certainly grate with the guiding influence of a rich tapestry of traditions that go back many generations. However, empowered farmers, determined to increase production sustainably, are prepared to explore all aspects of SRI practices, mindful of local agronomic conditions. To the extent that SRI is and will continue to be a successful innovation, an explanation for SRI's apparent popularity lies in the central role played by farmers.

Proponents of SRI argue that there are synergistic effects among the recommended practices, giving more increase in yield when all are used together rather than when practices are used singly and separately. Some are dismissive of any 'reductionist' approach which entails teasing apart the individual and combined impacts of specific components of SRI on plant growth. However, the claimed synergistic effect of components of SRI practice rekindles some latent issues that are still not given adequate attention, by either 'opponents' or 'proponents' of SRI. One such critical issue is the contribution of root vigour towards yield. The evidence that SRI produce vigorous plants with larger root systems has been recognized (Dobermann, 2004; Stoop, 2005), but why roots can make so much difference to yield is not fully understood. Therefore, the contribution of rice roots to the grain yield demands research intervention as a priority.

This chapter looks into several important questions. What is the scientific basis for the observed responses by individual plants and resulting crop yields to SRI growing conditions? What are the important gaps in knowledge that need to be addressed so that the potential benefits/limitations from SRI can be realized/identified? And what are the respective and collective roles of farmers, trainers and researchers in filling the gaps?

Attention has been drawn to the 'hidden half' of the plant and to evidence that indicates that SRI management practices might be increasing 'root activity' for better yield performance. A large body of research, mainly from Asia, validates some of the claims of SRI. In particular, the four basic management practices (see below) of SRI that appear to enhance root activity have been focused on. An integrated model for a high-yielding rice plant, relevant to both traditional and improved varieties and based on optimal root activity, is presented below. A collaborative approach by researchers and farmers is also discussed, based on SRI methodology and sound science, to enable farmers to provide optimal growing conditions for rice production that is sustainable both ecologically and economically.

SRI and the High-Yielding Theory of Rice Production

SRI is defined as a set of basic management practices (Stoop et al, 2002; http://ciifad.cornell.edu/sri) that includes:

- transplanting very young seedling (10–15 days old);
- rapid and shallow transplanting one or two seedlings with wider spacing (30 × 30cm or 40 × 40cm);
- practising alternate wetting and drying (AWD) during the vegetative phase (or keeping the soil moist but not continuously saturated);
- applying compost in preference to chemical fertilizer.

The SRI concepts developed by Fr. Laulaniè in the 1980s in Madagascar (Stoop et al, 2002), have many similarities with an earlier production approach (Horie et al, 2005) called 'High-Yielding Theory' (HYT) (Matsushima, 1973; Table 4.1). HYT was a yield-increasing strategy, researched and practised in some Asian countries, but largely overlooked during the Green Revolution period.

The one feature that differentiates SRI and HYT is plant density. SRI strives to increase yield by maximizing yield per plant, whereas HYT pursues the same objective by increasing plant densities per hectare. In doing so, HYT did eventually pay some attention to root activity but this effort was focused on increasing the number of aerenchyma mainly by genetic manipulation (Lee, 1980). The rationale was to minimize lodging at later growth stages which was the most common problem for rice plants grown with HYT. Although there was evidence that the main compound which influences plant growth and development through root activity was cytokinin (Richmond and Lang, 1957), this useful piece of information was largely ignored until recently. In the late 1980s it was assumed that higher root activity can increase a plant's physiological efficiency; but this concept was mainly acknowledged as a future breeding strategy (Kumura, 1989). The reason for not pursuing root activity was fairly obvious, i.e. the factors enhancing and maintaining root activity at later growth stages were not fully understood and explored; and so remained untouched.

Only recent research has corroborated Richmond and Lang's (1957) earlier findings that the highly efficient photosynthetic performance of super high-yielding rice cultivars is largely due to the increased cytokinin content in their roots (Shu-Qing et al, 2004), contributing to higher grain yield. In addition, it has also been found recently that, by minimizing plant density by transplanting a single seedling per hill, root quantity and cytokinin content are enhanced in the rice plant at later growth stages. This results in increased grain yield per plant due to

Table 4.1 *Model for cultivation of an ideal rice plant based on High-Yielding Theory (HYT)*

Yield	Percent of ripened grains	×	No of grains per unit area
Six prerequisite for ideal rice plant	(1) Necessary and sufficient number of grains for obtaining the target yield	(2) Many short panicles with short culms for realizing prerequisite (1) (2) Short, thick and erect upper three leaves	(4) Leaf colour not faded even after heading (5) As many green leaves per culm as possible (6) Favourable weather conditions for 40 days (15 days before and 25 days after heading)
Growth period	<u>Early growth period</u> Up to the leaf number index 69	<u>Middle growth period</u> Leaf number index 69 to 92	<u>Late growth period</u> Leaf number index 92 and later
Main target for cultivation	Securing number of panicles (tillers)	Controlling plant type (improving light receiving efficiency) Preventing lodging Improving physical condition	(Increasing the percentage of ripened grains)
Cultivation practices	Raising healthy seedlings Early season planting Heavy application of nitrogen in such a way that the nitrogen supply can be restricted in the middle growth period Shallow transplanting Prevention of root damage Dense planting	Restriction on nitrogen supply* Midsummer drainage	Topdressing of nitrogen (at the late spikelet differentiation and full heading stages) Making the root healthy (intermittent irrigation) Abundant sunshine (heading at most sunny time)

Note: * Measures to restrict nitrogen supply must be taken mainly during the early growth period.

Source: Matshusima, 1973

enhanced physiological efficiency of the plant (San-oh et al, 2006). The practice of planting a single seedling per hill, and its impact on root activity is one of the unique and novel components that could be explored using SRI management.

Theory of Root Oxidation Activity

Before we discuss SRI management practices in relation to root activity, we need to review the physiology of root activity; and how it influences the physiology of the rice plant by enhancing photosynthetic efficiency.

Roots supply nutrients and water, synthesize plant hormones, anchor plants and interact with soil biota. The physiological activities of roots contribute to the reinforcement of their oxidation activity. Oxidation activity in roots is measured by a phenolic redox pigment, particularly ά-napthylamine, which is widely employed to assess root activity. Rice root respiration has a proportional relationship with ά-napthylamine-oxidizing activity (Yamada and Ota, 1958). The oxidation rate is greater in new roots compared to old ones (Aimi and Fuzimaki, 1959). Therefore, by root activity, we are mainly focusing on root respiration.

Rice roots follow an aerobic pathway like other plant parts, although the root environment under flooded cultivation is hypoxic. For this purpose, lysigenous intercellular spaces, called aerenchyma, operate as an oxygen supply route to the roots (Yamada and Iyama, 1953). It was shown that the development of lysigenous intercellular space varied greatly according to the growing period and environmental conditions (Yamada et al, 1954; Arikado, 1955). Initially, it was believed that root activity increases with increased number of aerenchyma (to the extent that oxygen is a limiting factor in respiration) (Arashi and Nitta, 1955); and the number of aerenchyma not only varies with the growing environment, but also varies with the rice growth stages itself. In general, it has been found that flooded rice has its peak root activity from the beginning to the middle heading period, whereas upland rice has a wider peak compared to submerged rice (Mitsui and Tensho, 1952). It was argued that by increasing the number of aerenchyma, root activity can be enhanced. But later it was found that upland cultivars with fewer aerenchyma had higher root activity compared to lowland cultivars (Puard et al, 1986). Further, it was discovered that in addition to the supply of oxygen provided mainly by aerenchyma, sugar content of roots also has a close relationship with root respiration rate and activity (Tsuno and Yamaguchi, 1987).

The supply of photosynthates or sugar to the roots is mostly done by the lower leaves (Tanaka, 1958). Therefore it was suggested that, to sustain high root activity, it is necessary that the rice plant's configuration allows sunlight to reach the lower leaves as much as possible. Thus, the suggestion emerged to keep the upper leaves erect for this purpose. In addition, it was also found that oxygen supply to the roots is also easier from lower leaves than from upper ones and that withered lowered leaves, especially at later growth stages, lose their ability to take up and pass on oxygen (Arikado, 1975). Consequently, it was considered essential to keep lower leaves alive as long as possible so as to provide roots with both photosynthates and oxygen (Arikado, 1975). Thus a healthy root function depends on the rate of respiration, sugar content and oxygen supply.

Therefore, when the rice plant, especially the upland cultivars that have fewer aerenchyma compared to lowland cultivars, is grown under continuously flooded conditions with dense planting pattern, it retards the function of lower leaves and so the root activity, resulting in >75 per cent root degeneration at the time when flooded rice plants commence flowering (Kar et al, 1974), i.e. at a time when peak root activity is required by plants to achieve higher yield. Also, the lower oxygen concentration in the rhizosphere and continuous soil submergence results in more accumulation of carbon dioxide around the roots which speeds up the root senescence.

Impact of Root Activity on Plant Physiology and Yield

The details of how a healthy root system influences the physiology of the 'visible' plant, especially how it affects yield, are discussed here. For the purposes of discussion, indicators for root health are defined as root mass and respiration rate. In general, factors listed as responsible for increasing the physiological efficiency of rice plants include: canopy architecture (Takeda et al, 1984); single leaf photosynthetic activity (Park and Ota, 1969; Hayami, 1983); root activity and root quantity (Lee, 1980; Jiang et al, 1985); and plant adaptability to pure stands or monoculture (Donald, 1968, 1981; Ishi et al, 1986). All these factors are closely dependent on root activity since higher ά-naphthylamine-oxidizing activity of roots is correlated with higher chlorophyll content of the leaves, slower leaf senescence (Ota and Lee, 1970; Youn and Ota, 1973), and more erect standing leaves.

These important findings reflect the causality in the relationship between above-ground and under-ground plant parts. Similarly, Jiang et al (1985) suggested that if root activity is kept high during the ripening period, leaf blades will maintain their upright posture; and they will also age more slowly, delaying both withering and declining photosynthetic activity. In addition, they also found that when root activity is high, the photosynthetic rate does not decline so much in the afternoon. Therefore, these authors concluded that keeping root activity high is very important to maintain the functioning of the source, i.e. higher photosynthetic efficiency of the leaves during the ripening period. The conundrum was how to do just that since HYT was based on the supposition that higher yields were dependent on higher plant densities, leaving little scope to reduce the root activity-inhibiting effects of shading. A partial solution was suggested by Matsushima (1973) – intermittent irrigation at later growth stages to stimulate root activity. Based on Matsushima's suggestion, Tsuno and Wang (1988) concluded that drained field conditions could induce higher root activity by enhancing root respiration and root revitalization, resulting in greater leaf area, higher photosynthesis activity and higher yield. Recently, these finding have been complemented by another two major findings, i.e. high root activity contributes to a higher photosynthetic rate (Osaki et al, 1997), and the growth of shoots is very much dependent on root growth (Nikolaos et al, 2000).

Another valuable clue regarding the importance of root growth derives from the suggestion of Xuan et al (1989) that root quantity, as well as root activity, are both required for raising yield. This suggestion came after the discovery by Terashima et al (1988) that a super high-yielding cultivar has larger root systems compared to other indigenous cultivars.

In general terms, a larger root surface area is associated with higher cation exchange capacity, and thus more nutrient uptake becomes possible. Further, greater root quantity also correlates with drought tolerance. Several research groups have shown that, in the case of drying soil, water deficits first appear near the surface and then progress to the deeper layers; increased depth of rooting is common under these conditions (Proffitt et al, 1985; Newell and Wilhelm, 1987). Thus, root systems can be enhanced (deepened) by lowering soil moisture status, during the vegetative stage, providing a buffer against drought conditions.

This finding is in agreement with earlier findings (e.g., O'Toole and Chang, 1979; Yoshida and Hasegawa, 1982) that those cultivars which are characterized by higher ratios of deep root weight to the weight of the above-ground plant parts have a higher drought-tolerance score. The force required to pull up rice seedlings from the paddy soil is correlated with root weight, root branching, and thick root number (O'Toole and Soemartono, 1981). Based on the relationship between root abundance and drought tolerance, Ros et al (2003) recently proposed seedling selection with higher shoot/root ratios as a means of increasing drought tolerance and yield.

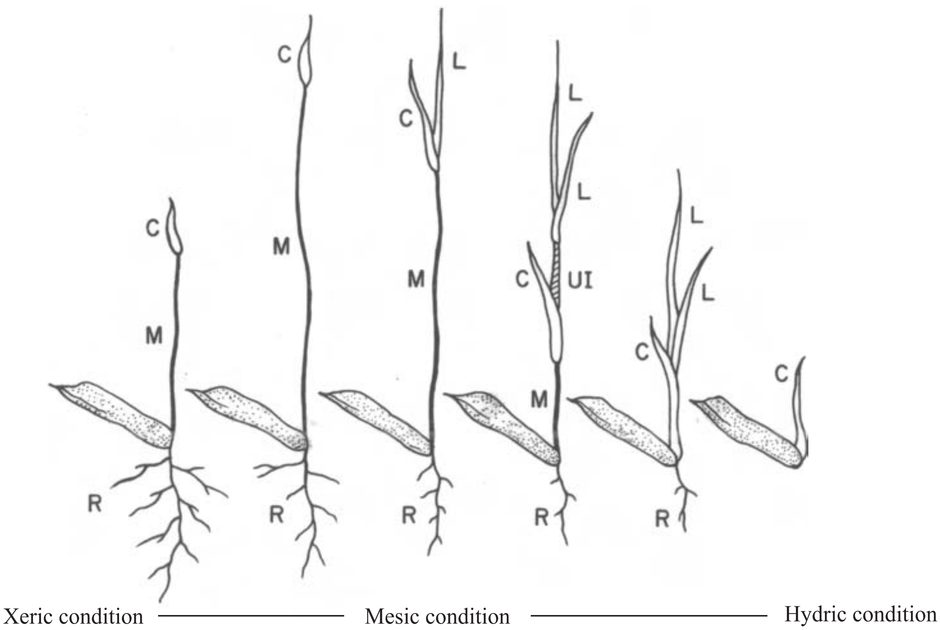
Thus there is abundant evidence to confirm the crucial role of the 'hidden half' plant parts in co-determining grain yield; this becomes all the more important when the crop needs to be managed under limited soil moisture conditions. However, despite these supporting facts, the importance of root activity in relation to yield has been given limited attention in rice research. One of the reasons for this oversight might be the dramatic success of the 'Green Revolution' which eclipsed, by and large, almost all traditional cultural practices in Asia, including HYT-based techniques. Perhaps it was also a case of out of sight, out of mind!

Only recently the 'half told' story of rice roots resurfaced when SRI practice became more widely known, when rice plants showed more vigorous root growth irrespective of cultivar species under SRI management. This indicates that the cultural practices recommended in SRI have an influence on root quantity and root activity and so provide the basis for reviewing basic management practices of SRI which might have an influence on root activity and quantity.

SRI Management and its Relation to Root Quantity and Activity

Growing seedlings in well-drained nursery beds with fewer seeds, and transplanting at the 2–3 leaf stage (germination and early seedling growth)

Although rice plants are 'semi-aquatic' and seeds germinate well in water (unlike true aquatic plants, the germination of rice is not inhibited by lack of oxygen), this does not mean that rice is an aquatic plant that grows better under submerged



2.69	2.35	1.40	1.30	0.75	
50	100	150	200	250	

Note: Where M = mesocotyl, C = coleoptile, R = root, L = leaf.

Equivalent values are shown between pF and percent scale: e.g. 2.69 is equivalent to 50% moisture content in the medium (vermiculite).

Figure 4.1 *Relationship between seedling growth and moisture content in a culture medium*

conditions. Many studies have examined the germination pattern of rice seeds under submerged conditions (Yokoi, 1898; Sasaki, 1926; Takei, 1941; Takahashi, 1978). These researchers have concluded that low oxygen tension in water caused elongation of coleoptiles and the prevention of radicle growth at initial stages. When Takahashi (1978) looked at the growth pattern of seedlings under different levels of moisture content in the media (Figure 4.1), he found that the elongated growth of the mesocotyl took preference over that of the coleoptile until near pF 2.4 (the forces necessary for plants to extract water from the soil for their use); then, as the pF was further lowered, coleoptiles growth occurred preferentially. No growth of the mesocotyl occurred under saturated condition. Takahashi (1978) reported that at lower oxygen tension in the water (as with hypoxic condition) compared to the atmosphere, several metabolites including carbon dioxide are accumulated in the surrounding root media and adversely affect seedling growth.

Similarly, Kordon (1974a, 1974b) reported that the primary and adventitious root growth was prevented by less oxygen in the root media.

Ros et al (2003) also showed that increased competition for nutrients at higher seed rates in the nursery bed reduced seedling vigour after transplanting. Based on these two facts it may be assumed that the SRI practice of maintaining well-drained soil in an SRI seed bed helps roots to grow at the very early seedling stage. At the same time, less inter-plant competition due to reduced seedling density helps seedlings access more growth-promoting nutrients, leading to healthier seedlings. Thus SRI seedlings are heavier and sturdier compared to seedlings grown in conventional nursery beds (Stoop, 2005).

Transplanting rice seedlings at a younger stage has been supported by many researchers (Ota, 1975; Yamamoto et al, 1995; Horie et al, 2005). This practice captures the benefit of the early phyllochron[1] stages (less than four leaves) having higher potential to produce more tillers/plant (Katayama, 1951). However, in the SRI method, special attention has also been given to careful uprooting and then gently transplanting seedlings immediately into the field with minimal root loss so as to minimize transplanting trauma. This practice makes an important contribution to subsequent root vigour and activity and hence to overall yield performance, compared to conventional management practices. In addition, SRI practice also suggests that the seed sac along with the soil attached to the seedling should be kept intact while uprooting to ensure that the endosperm is still attached, so that there is maximum sustained nutrition of the young plant. In general, uprooting causes stress to the seedling which could be minimized when the endosperm remains attached (Sakai and Yoshida, 1957; Ota, 1975; Hoshikawa et al, 1995).

In conventional management practice, it has been reported that around 40–60 per cent of the root remains in the soil during pulling up from the nursery. Pruning up to 60 per cent of the root during transplanting significantly decreased subsequent root and shoot dry matter (Ros et al, 1998). This suggests that a considerable loss of roots at the seedling stage affects seedling vigour and hence yield. Therefore, it may be suggested that SRI practices lead to increased shoot and root dry matter by protecting root systems during transplanting. SRI practices lead farmers to give greater attention to the conditions of growing, uprooting, storing, transporting and planting seedlings; and the effects that these practices have on plant development and yield.

One important factor that influences plant morphogenesis, and which has a profound influence on the formation of roots and shoots and their relative growth, is the level of cytokinin in the plant. As a phytohormone that is mainly synthesized in the roots, cytokinin has a significant effect on tiller bud formation (John et al, 1993; Bangerth et al, 2000); it mobilizes plant nutrients (Li et al, 1992), delays leaf senescence, regulates chloroplast development, and determines sink–source relationships (Hutchinson and Kieber, 2002).

Therefore, it may be assumed that SRI plants, at the seedling stage, that have more root quantity compared to conventionally grown rice seedlings, also have a greater supply of cytokinins. The implication of this for tiller development is discussed later. In addition, higher root quantity should enhance both nutrient and water-absorbing functions. This assumption is in agreement with the finding of Hanada (1976) where tiller bud formation was promoted by the application of kinetin to the rice roots at the five leaf stage.

In summary, careful transplanting at the 2–3 leaf stage should yield improved results as seedlings enjoy the benefit of both endosperm nutrition and of newly formed roots. However, careful and early transplanting requires increased skill, and hence labour; but once farmers realize that there is a set of options to evaluate in growing and transplanting seedlings that will have an impact on production and yield without heavy demands for costly inputs, rigid traditional practices will be seen in a new light.

Transplanting single seedlings with wider spacing

Plants grown with wider spacing have more area of soil around them to draw nutrients from. Such plants also have better access to solar radiation for better photosynthesis. Hence they perform better as individual plants. Consequently, there should be no mystery about why SRI plants invariably perform better than conventionally managed rice in terms of yield per plant. The reason for the deviation of this linearity in the case of grain yield per plot is that the yield is not entirely dependent on the performance of the individual plant. It is also a function of the total number of panicles per plot and on the other key yield-contributing parameters, number of filled grains per panicle and grain weight. Clearly, spacing is critical in modifying the components that influence final yield. In this regard, Takeda and Hirota (1971) showed that grain yield was unchanged between planting densities from 10 to 100 hills per m^2.

There is significant interaction between varieties and spacing. Generally, long-duration varieties do better with wider spacing than short-duration varieties (Baloch et al, 2002). This is in agreement with the recent finding of Stoop (2005) who suggested that long-duration varieties will perform better under SRI management practice. These responses support the hypothesis (Kira et al, 1953) that, with increasing planting density, biomass yield reaches a ceiling value that is limited by the supply of resources. The supply of resources mainly depends on the root system activity. So, it can be suggested that wider spacing allows roots to grow profusely along with production of more tillers per plant.

Under SRI management it can be suggested that early transplanting provides a longer vegetative growth period, and single seedling per hill reduces competition and helps to minimize the shading effect on lower leaves. This helps lower leaves to remain photosynthetically active, for much longer; and, in turn, root activity remains higher for a longer period due to the plant's enhanced supply of oxygen and carbohydrates to the roots (Tanaka, 1958; Horie et al, 2005). Further, higher root activity, in turn, supplies cytokinins to the lower leaves, delaying senescence and helping to maintain photosynthetic efficiency of the plant at later growth stages. This outcome has been confirmed by a recent research finding where single seedling per hill had higher yield compared to three seedlings per hill (San-oh et al, 2006). In addition, they reported that plants with one seedling/hill had greater numbers of crown roots, root length density and cytokinin content compared to plants with three seedlings/hill. The photosynthetic rate at later growth stages was significantly higher in single seedling/hill compared to three seedlings/hill.

However, single seedling/hill may be justified with the concept that the yield-contributing parameter within the plant can be modified by manipulating intra-hill interactions; still, inter-hill and row spacing need to be adjusted according to varietal characteristics (plant height, leaf area index, leaf posture and plant canopy area) to achieve optimum plant population per plot to realize higher yield potential under SRI management practices. Once again, farmers are well placed to experiment with spacing and its relation with varieties and crop yield. Increased spacing with younger seedlings runs counter to the traditional experiences of rice farmers and is one aspect of SRI that is approached with much scepticism by farmers who are experimenting with SRI concepts for the first time, with even more scepticism from neighbouring farmers. However, the impact of these practices on plant growth is sufficiently spectacular that neighbouring farmers start asking, 'what variety are you using?' Regardless of the eventual merits of SRI, it stimulates self-development and increased ownership by farmers of their production processes.

Intermittent irrigation

In recent years, the main aim of developing intermittent irrigation of rice has been to save water. It was reported that 25–50 per cent of water used could be saved by this method without any adverse effect on rice yield (Ramamoorthy et al, 1993; Tajima, 1995). In contrast, it has also been reported that intermittent irrigation increased water consumption and water stress, decreased leaf area index, induced early senescence and decreased the rate of photosynthesis and net assimilation rate (Lu et al, 2000). Recently, Belder et al (2005) have found that in aerobic rice culture, crop growth and yield was limited by water deficits and not by nitrogen deficiency. However, it was also found that growth is not harmed when plants are exposed to limited water conditions during their vegetative stage (Boonjung and Fukai, 1996). These authors concluded that the plant adopts osmotic adjustment at the vegetative stage which constitutes the most noticeable mechanism of dehydration tolerance in the rice plant (Steponkus et al, 1980). But, any drought stress at later stages in plants which are not exposed to such drying treatment can cause great loss, especially when plants are in the early reproductive phase (Kobata and Takami, 1981).

Interestingly, in HYT, intermittent irrigation served a different purpose. According to the HYT theory, the so-called 'broken irrigation' method was used to control tillering, improve soil conditions and to maximize efficiency at harvest by changing the sink–source relationship. The 'broken irrigation' method entailed the following procedure: after flooding the field, water intake was cut so as to let the water level go down gradually until the soil surface appeared, the field surface was exposed to air for three to five days, and then flooded again.

These findings indicate that intermittent drying in the vegetative stage may not only induce root growth into deeper soil layers but could also help the plant to develop xeromorphic characteristics. Intermittent drying also improves soil, stimulates tiller development and alters sink–source relationships. These findings are very illuminating for current rice production situations where various efforts are focusing on producing more food with less water.

In relation to root activity, it has been found that the three yield-improving components, that is, tiller development, soil condition and sink–source relations, have a close relation with cytokinin production which is regulated by root activity. It is greatly regulated by environmental conditions such as nitrogen availability, soil moisture condition, root mass, etc. Another phytohormone which is closely linked to nitrogen status of soil and may vary with the intermittent irrigation is auxin. Evidence exists that indicates that auxin induces lateral root formation while cytokinin helps in their elongation (Debi et al, 2005).

The hypothesis that cytokinin concentration is regulated by N (Kuiper et al, 1988) is supported by the positive relationship between N supply and cytokinin production (Mercier et al, 1997). It has also been indicated that production of cytokinin, as well as biomass, is stimulated by a mixed N source (NO_3^- : NH_4^+ ratio 1:1) (Wang and Below, 1996; Briones et al, 2003) rather than any single source. This statement is in agreement with the finding, reported by Kronzucker et al, (1999), that rice yields can be 40–60 per cent higher for any given amount of nitrogen taken up if the N is equally divided in forms between ammonium (NH_4) and nitrate (NO_3), rather than being entirely absorbed as ammonium. This synergistic mode of uptake is still poorly understood, but has been reported repeatedly in the literature (Ta and Ohira, 1981; Ta et al, 1981; Smiciklas and Below, 1992). Interestingly, hybrid rice cultivars, which tend to have higher root activity and quantity compared to traditional cultivars, are also more responsive to mixed sources of nitrogen (Luo et al, 1993).

A second important factor which influences cytokinin is soil nitrogen. The status and availability of soil N are dependent on the soil's aerobic/anaerobic environment. This influences the rate of N mineralization resulting from microbial decomposition of organic matter. In this context, it is reported that microbial decomposition responds to soil water content and to intermittent drying. The latter kills off a large portion of soil microbes, thereby releasing N for plant uptake during rewetting cycles (Birch, 1958; Bottner, 1985; Kieft et al, 1987). These findings indicate that soil nitrogen status may be enhanced, in terms of maintaining a balanced ratio of NO_3^- : NH_4^+ nutrition to enhance root-available nitrogen. These, in turn, regulate cytokinin, and therefore, root activity. NO_3^- increases the auxin:cytokinin balance required for tiller and biomass production, while urea and NH_4^+ shift this ratio in favour of cytokinin (Mercier et al, 1997), probably delaying root senescence at later growth stages. This is important in the context of SRI management practices where, after intermittent irrigation, shallow flooding has been recommended during the reproductive stage. This late flooding practice allows NH_4 to dominate, hence favouring cytokinin production.

A third component that affects cytokinin content is the root mass. It has been indicated that quantitative root growth is higher in high-yielding cultivars (Kim et al, 1985; Harada et al, 1988). These cultivars transport larger amounts of cytokinin to the above-ground parts of the plant during the ripening stage. This has the effect of suppressing a decline in rubisco content (Ookawa et al, 2004), resulting in a higher rate of grain filling and delayed senescence of the plant.

Since higher root mass is a greater supplier of cytokinin compared to fewer roots, there is evidence to indicate that intermittent irrigation may increase root mass during vegetative stages (Matsuki and Katsutani, 1940; Baba, 1977) and stimulates more root activity, and hence more cytokinin content. This favourable outcome can be achieved by maintaining higher rates of cytokinin production at a later growth stage, first by following intermittent irrigation during vegetative stage and then by maintaining shallow flooding during the reproductive phase. Clearly, this is not possible under completely flooded conditions because of the lesser quantity of roots and minimal root activity since, under continuously flooded conditions, over 75 per cent of roots degenerate by the time plants are entering their reproductive phase. (Kar et al, 1974).

This adaptive trait could be exploited to manage rice crops under limited water conditions without compromising grain yield. This could also be why farmers claim that they experience better yield with SRI practice compared to conventional production methods under drought conditions.

Application of compost

The fourth management practice of SRI is compost application. In general, plant root growth is greatly affected by the soil environment and, in this context, the effect of organic manure on soil is well known. The incorporation of organic manure into soil can bring beneficial effects to root growth by improving the physical and chemical environments in which roots grow (Sidiras et al, 2001; Yang et al, 2004). These non-biological aspects of the soil create a productive biological environment by stimulating root growth-promoting bacteria (Timmusk, 2003). In addition, the effectiveness of organic manure in improving root growth and nutrient uptake by rice plants is significantly different under different water regimes. For example, continuous water logging significantly decreases root growth (Sahrawat, 2000), whereas under intermittent irrigation, the incorporation of organic matter improves root morphological characteristics and root activity of rice plants. It has the effect of increasing root density, active absorption area, root oxidation ability and nutrient uptake (Yang et al, 2004).

There are immense benefits from compost application in rice farming given that compost improves the soil's physical, chemical and biological properties. And, therefore, it is not surprising that SRI recommends application of compost. However, the question of compost availability for large areas needs to be addressed.

First, it is clearly stated that application of compost in SRI practice is optional (http://ciifad.cornell.edu/sri/proc1/sri_03.pdf), even though some proponents of organic production present SRI otherwise (Schiller, 2004). This flexibility indicates that the observed positive SRI responses are not entirely based on organic fertilizer as it is assumed by some SRI critics (Sinclair and Cassman, 2004). However, in the past, agricultural utilization of organic materials was the common traditional practice in Asia when rice was produced and consumed locally. But, more recently, widespread introduction of chemical fertilizers together with the high costs of labour and transport of organic manure, plus diminished availability of biomass in some or many places, has led to a decline in the use of organic materials in cropping systems. At the same time, intensification of crop production and urban concentration have led to a large increase in the production of agricultural waste in many regions of the world. As with other grain crops, rice production is now more akin to an open-cycle extractive industry, driven by externally supplied synthetic inputs with nutrients being transported to urban concentrations, ultimately ending up as displaced pollutants. And in the absence of effective recycling procedures, the remaining crop residues are often mismanaged, leading to further nutrient loss.

The promotion of compost application in SRI serves two purposes: for farmers, it draws attention to the vital importance of soil structure and biology in growing a healthy crop sustainably; and for governments, it highlights the need to address the bigger question of returning nutrients to the rice paddy from the urban concentrations once the grain has been consumed and discarded as human waste. SRI advocates argue that the more extensive root systems of SRI plants and the improved soil structure and biology, induced by compost applications, provide access to a much larger pool of nutrients (Uphoff, 2003). To the extent that these claims are valid, they only provide a breathing space until agricultural production systems return to the closed cycle practised with traditional rice production.

Moving Ahead from HYT to SRI

It has been revealed that SRI management practices for rice production in Asia have strong linkages with the previous cultural practices such as HYT. Of course, SRI-inspired farmers appreciate the considerable savings in labour and seed costs, if they can reduce seedling density without compromising on yield. But why is SRI proving more successful in spreading than HYT, whose success was limited to a few farms where farmers could access large amounts of compost?

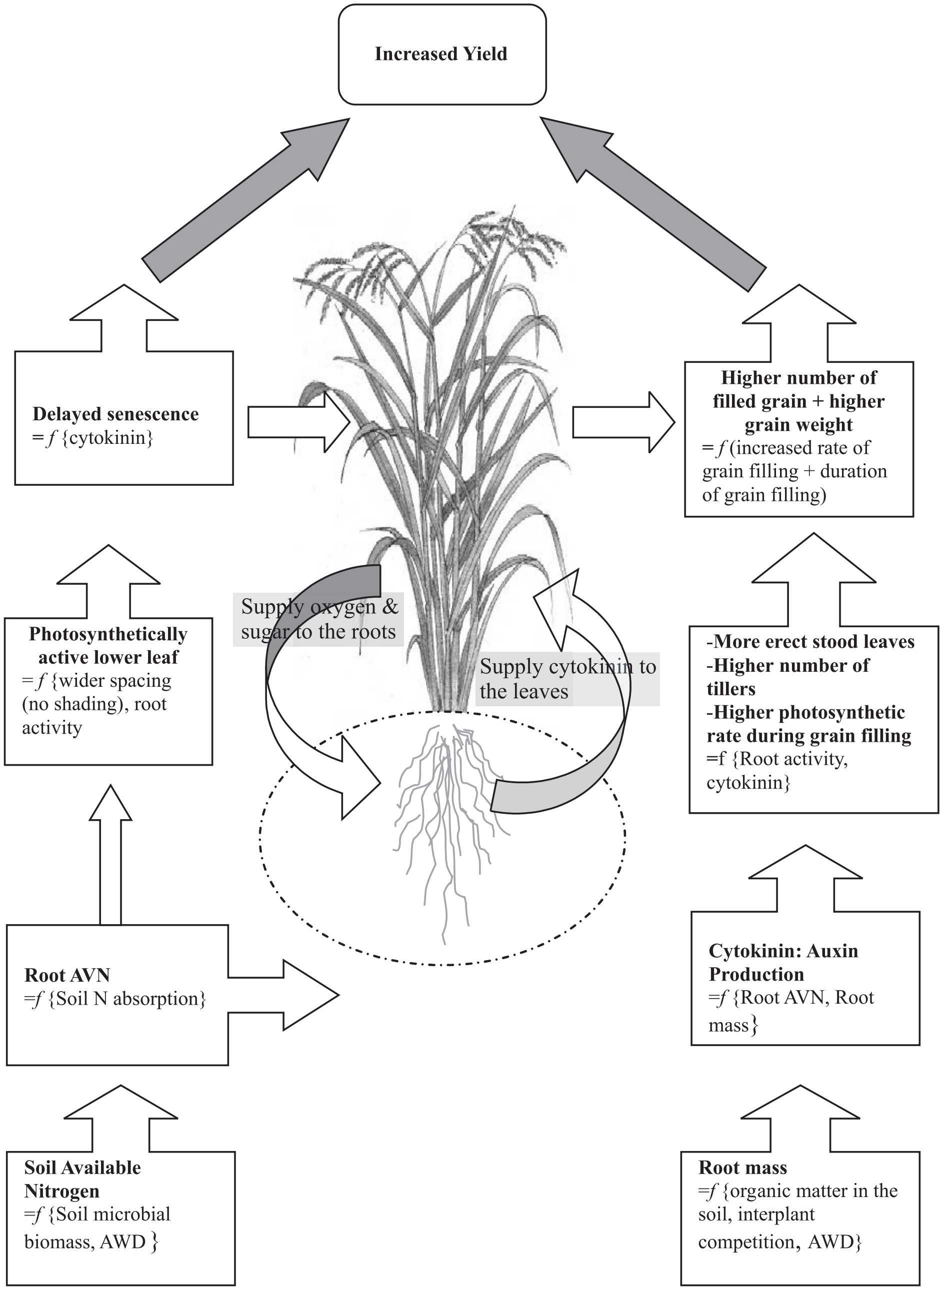
Matsushima (1973) suggested that in adopting HYT for high yield, the first step is to prepare a large ‘container’ and second is to fill this container with rice. By ‘container’ he means the number of spikelets per square metre, and the content of the container is the percentage of ripened grains. For the first step he suggested that there should be dense planting to secure the maximum number of tillers per square metre, and hence in turn the greatest number of grains per square metre. To achieve this, he suggested that the plant should absorb as much as nitrogen as possible without compromising plant health. Since lodging – and thus reduced photosynthesis capacity – at a later stage was the major constraint, he also added that improvement should also be made in the light-receiving efficiency of the rice crop. For this, he suggested revitalizing the roots by intermittent irrigation at later growth stages to increase root longevity. The idea was that this would prevent lodging and improve the physical condition of the plants by restricting their nitrogen absorption during the middle growth period while it will also help to maintain root function at later growth stages.

However, it proved extremely difficult for the growers to properly manage high plant density rice crops without lodging. And hence, just as there were a number of successful cases, there were various studies reporting failure also. Failures in securing sufficient number of grains per unit area explained most of the disappointing results (Kumura, 1989). This occurred mainly because of the unfavourable growth of the crops during the early growth period where plants were not able to absorb as much nitrogen as is required for achieving sufficient grains per unit area. It was based on the fact that the number of grains per square metre is in direct proportion to the amount of nitrogen absorbed by the rice plants per square metre during the late spikelet differentiation stage, and so a higher number of grains could not be achieved unless the plant is made to absorb much nitrogen. Therefore, without efficient promotion of root growth in early growth periods, high yields could not be realized. The latter provides a basis to support the SRI view that seedling vigour with healthy roots is important, and why sparse planting is needed along with intermittent irrigation during the vegetative period in order to realize the high yield potential of the rice plant.

The above presented review on root activity and quantity provides enough evidence to suggest that the physiological efficiency of the plant is improved by enhancing cytokinin activity, first by increasing root quantity and activity; second, by increasing root longevity; and third, by regulating available soil nitrogen status.

An Integrated Model of High-yielding Rice Plants Under SRI Management Practices

The above review and interpretation allow us to propose the following integrated SRI model of the rice plant with appropriate emphasis on optimal root activity (Figure 4.2).



Note: All variables are shown as functions (*f*) of the variables that drive them. (AVN = available nitrogen, AWD = alternate wet and dry).

Figure 4.2 *Integrated model of the high-yielding rice plant under SRI management practices*

Younger seedlings with higher root–shoot ratio encourage root–shoot growth along with higher rates of cytokinin synthesis

A most important crop production objective during the early growth period is to secure the optimum number of tillers per square metre. Tiller production and panicle development (at later growth stage) is related to cytokinin synthesis in the root along with the number of phyllochrons of growth completed.

Transplanting single seedling per hill further enhances root growth and root activity when grown with AWD during the vegetative period

To realize the full potential of tiller development, it is necessary to improve the light-receiving efficiency of the plant, prevent lodging and to improve the physical condition of the plant. This could be enhanced by further root growth and activity (1) by minimizing inter-plant competition and (2) by reducing leaf area density which will ensure more erect and upstanding leaves without any shading effect. At the same time, AWD will encourage root growth into deeper layers of soil. This will maximize the roots' surface area for better nutrient uptake. Greater root length will also minimize water stress should the plant be exposed to drought conditions during any period of crop growth.

AWD enhances microbial response and regulates the most available nitrogen forms in the rhizosphere

AWD should balance the NO_3:NH_4 ratio in the rhizosphere with higher root length density for higher biomass production and should also regulate cytokinin-auxin production for better tiller development. This effect could be further enhanced when the soil has sufficient organic matter to reduce leaching loss of NO_3 along with higher root growth at deeper layers of soil.

Shallow flooding during the post-anthesis period maintains higher cytokinin content with higher root activity

Cytokinins are high nitrogen-demanding compounds so cytokinin production increases sharply during high root nitrogen events which could be induced by supplying the NH_4 form of nitrogen by shallow flooding during the grain-filling stage. This would be better realized with higher root surface area and higher cation exchange capacity as high root nitrogen events result from increased root absorption of nitrogen from the soil as well as mobilization of stored nitrogen in the rhizosphere.

Higher root growth and activity increase physiological efficiency of the rice plant

Prolonged photosynthetic efficiency of the lower leaves could be maintained by avoiding shading between plants and by keeping root activity high during later growth stages. In turn, the photosynthetically active lower leaves would provide sugar as well as oxygen to maintain high activity of the roots during the later growth period.

Discussion

There is sufficient documented evidence to suggest that integration of the four key management practices of SRI could produce better on-farm yields compared to conventional production methods through improving the physiological efficiency of the rice plant. Therefore, one can challenge the contrary argument of McDonald et al (2006) that there is no correlation between these four practices and the physiological efficiency of the rice plant. Further, a careful review of the existing agronomic literature confirms that SRI practices have a sound scientific base (Horie et al, 2005).

High-yielding varieties (HYVs) and hybrid cultivars which are highly responsive to chemical fertilizers can have a clear place in SRI. Anthofer (2004) suggested that modern varieties also respond positively to SRI practices. SRI-grown plants show higher root growth (Stoop, 2005), but, interestingly both HYVs and hybrid rice do have higher root growth and activity compared to traditional varieties (Harada et al, 1988; Ookawa et al, 2004). These issues need to be addressed and investigated by systematic research focusing on varietal responses to SRI practices, particularly on root growth and its relation to yield.

Further, it seems reasonable to infer from a wide body of relevant research that all four SRI management practices have synergistic effects on root growth. However, a greater opportunity for productivity gains exists by using just the two major components that have attracted the greatest interest of thousands of farmers in Cambodia (Anthofer, 2004), i.e. using less seed and less water by planting single seedlings per hill with wider spacing and intermittent irrigation. In this context, giving emphasis to growing and transplanting vigorous seedlings singly is more pertinent than simply recommending planting single seedlings. Seedling vigour with minimal root disturbance needs to be taken into consideration along with seedling age in order to realize higher yield potential. Little differences in yield were found between SRI and conventional management practices in the three Chinese trials that Sheehy et al (2004) reported. This is an important finding since in both practices single seedlings were transplanted. Fortunately, there is now evidence that a single seedling per hill increased yield compared to three seedlings per hill. This effect was due to higher root growth and root activity which delayed senescence and increased the rate of photosynthesis at later growth stages (San-oh et al, 2006).

Further Sheehy et al (2004) reported fewer panicles per square metre in SRI than with conventional production methods. This accords with our claim that hill spacing needs to be decided according to varietal characteristics, most notably tillering capacity. This factor may be one of the reasons for yield variation observed under SRI practices either at the same or different locations.

The second major component that many farmers can adopt is water management according to SRI principles. It is evident from the literature that AWD, or intermittent irrigation, is already a component of water management practices of Asian rice-growing countries such as China, Japan and Korea. AWD is currently being evaluated and promoted among rice farmers producing in water-limited environments (Bouman and Tuong, 2001). But, in general, traditional practices focus on intermittent irrigation at later growth stages (Matsushima, 1973; Sheehy et al, 2004), while SRI recommends AWD at the vegetative stage. Certainly, in the latter case, due to a temporary drying effect at early growth stages, plants would develop with osmotic adjustment and develop more roots at a deeper soil layer. This root induction practice at the early vegetative stage may be useful for plants grown under limited water conditions such as aerobic rice cultivation where water stress has been found to be a more limiting factor than any other stress. It has been found that under these situations, water stress reduces crop nitrogen demand (Belder et al, 2005*)* and hence yield is significantly reduced. However, temporary drying through intermittent irrigation also affects soil nitrogen status by changing nitrification–denitrification and/or ammonia volatilization processes. This can lead to more nitrogen loss compared to completely flooded conditions, especially in soils with low organic matter.

Research opportunities lie in the measurement of redox potential at increased depths in the soil. This information may explain the pathway of nitrogen transformation processes in situations where deep root systems might get an advantage of transformed nitrogen (ammonium form) in the deeper soil layer, i.e. under a reduced soil environment. Moreover, if the AWD/intermittent irrigation practice at the vegetative stage is integrated with the split dose of nitrogen at crucial growth stages, this may overcome many limitations of aerobic rice culture and intermittent irrigation practice.

Apart from this, changing the soil status from aerobic to anaerobic by practising AFD (alternate flooding and drying naturally) three–four times during the vegetative stage can improve plant type, light-receiving ability and resistance to lodging, along with root health. But again it is important to consider when and how long the intermittent irrigation should be applied to save water as well as increase yield since rice root–shoot responses and their physiology also differ at the genetic level along with environmental factors. Certainly, these scientific considerations of SRI principles and related research questions offer opportunities for further studies.

Reported cases where SRI plants performed no better than best management practices, as claimed by critics of SRI, cannot be ignored (Sheehy et al, 2004; Latif et al, 2005). In this context, we note that Stoop and Kassam (2005) contend that neither SRI advocates nor its critics have a complete understanding of the biophysical basis of the relatively higher yields. It is noted that (e.g. McDonald et al, 2006) there is a wide yield gap between farmer's practice and best management practice. However, realization of the 'on-farm management issues', by both groups, is the most important outcome from the current debate on 'SRI'. The 'miracle' is not so much that SRI *practices* can lead to exceptional yield performances – we believe this is explicable from the existing literature – but that the *process* of investigating 'SRI' encourages farmers and researchers to think seriously, and as partners, about how to grow a healthy crop sustainably. The phenomenon of SRI should help the research community reach the millions of small farmers in developing countries to meet the future rice demand. We need a new paradigm in technology generation and transfer, and SRI seems to be promoting this outcome.

The primary focus and challenges of the past were mainly to increase food production; but the present scenario is quite different. The challenges are multifold where food production has to be increased by countering other challenges such as global warming, water scarcity, soil fertility degradation and misuse and overuse of farm chemicals. At the same time, social changes and a growing concern for the environment have brought about a recognition of the 'multifunctionality' concept (Molden et al, 2000). The quality and quantity of all the products embracing 'multifunctionality' depends on how the farmers treat them with confidence and appreciation. Modern agricultural research often focuses more on increasing productivity per se and ignores social externalities; it is largely built on technologies that maximize biological uniformity and ignores the natural ecosystem. Certainly, this approach is not optimal for managing sustainable production systems. Hence it demands a paradigm shift in technology development and adoption. Millions of smallholder farms in developing countries where SRI is showing promise reflect the importance of involving farmers in such activities. This requires a participatory approach to knowledge creation and innovation such as Farmers Field Schools (FFS) to empower farmers as experts in growing healthy crops efficiently in an economic and sustainable manner (Whitten and Settle, 1998). The success to date of the 'SRI movement' where it competes with the best available technology justifies applying these cooperative approaches for mitigating food demand without relying too heavily on imported technology

Conclusion

The combination of cultural practices recommended in SRI increases the physiological efficiency of rice plants through enhanced root activity and provides many alternatives to enhance resource-use efficiency. There is a sound basis in the existing literature which allows us to put SRI in scientific purview; but the practical constraints in managing a favourable interaction of the plant–soil environment should not be underestimated. However, these constraints could be minimized if SRI is used as a heuristic vehicle for linking rice research with participatory farmer empowerment programmes. The SRI movement should be seen as a unique opportunity to integrate science with the society for sustainable development. Moreover, SRI should be seen as a means of enhancing system productivity and not merely as a vehicle for increasing yield.

Note

1 Phyllochron – a periodicity in plant growth expressed as the number of days to complete a unit of growth which produces one or more phytomer (the unit of plant growth in gramineae species, consisting of a leaf and subtending internode with a tiller bud at its base) (Stoop, 2005).

The Struggle to Govern the Commons

Thomas Dietz, Elinor Ostrom and Paul C. Stern

In 1968, Garrett Hardin[1] drew attention to two human factors that drive environmental change. The first factor is the increasing demand for natural resources and environmental services, stemming from growth in human population and per capita resource consumption. The second factor is the way in which humans organize themselves to extract resources from the environment and eject effluents into it – what social scientists refer to as institutional arrangements. Hardin's work has been highly influential[2] but has long been aptly criticized as oversimplified.[3–6]

Hardin's oversimplification was twofold: he claimed that only two state-established institutional arrangements – centralized government and private property – could sustain commons over the long run, and he presumed that resource users were trapped in a commons dilemma, unable to create solutions.[7–9] He missed the point that many social groups, including the herders on the commons that provided the metaphor for his analysis, have struggled successfully against threats of resource degradation by developing and maintaining self-governing institutions.[3,10–14] Although these institutions have not always succeeded, neither have Hardin's preferred alternatives of private or state ownership.

In the absence of effective governance institutions at the appropriate scale, natural resources and the environment are in peril from increasing human population, consumption and deployment of advanced technologies for resource use, all of which have reached unprecedented levels. For example, it is estimated that 'the global ocean has lost more than 90% of large predatory fishes' with an 80 per cent decline typically occurring 'within 15 years of industrialized exploitation'.[15] The threat of massive ecosystem degradation results from an interplay among ocean ecologies, fishing technologies and inadequate governance.

Inshore fisheries are similarly degraded where they are open access or governed by top-down national regimes, leaving local and regional officials and users without sufficient autonomy and understanding to design effective institutions.[16,17] For example, the degraded inshore ground fishery in Maine is governed by top-down

Figure 5.1 *Comparison of landings of groundfish (gadoids, solid line) and lobster (dashed line) in Maine from 1980 to 2002, measured in millions of kilograms of groundfish and lobsters landed per year. International fishing in these waters ended with the extended jurisdiction that occurred in 1977*

rules based on models that were not credible to users. As a result, compliance has been relatively low and there has been strong resistance to strengthening existing restrictions. This is in marked contrast to the Maine lobster fishery, which has been governed by formal and informal user institutions that have strongly influenced state-level rules that restrict fishing. The result has been credible rules with very high levels of compliance.[18–20] A comparison of the landings of groundfish and lobster since 1980 is shown in Figure 5.1. The rules and high levels of compliance related to lobster appear to have prevented the destruction of this fishery but probably are not responsible for the sharp rise in abundance and landings after 1986.

Resources at broader scales have also been successfully protected through appropriate international governance regimes such as the Montreal Protocol on stratospheric ozone and the International Commission for the Protection of the Rhine Agreements.[21–25] Figure 5.2 compares the trajectory of atmospheric concentrations of ozone-depleting substances (ODS) with that of carbon dioxide since 1982. The Montreal Protocol, the centrepiece of the international agreements on ozone depletion, was signed in 1987. Before then, ODS concentrations were increasing faster than those of CO_2; the increases slowed by the early 1990s and the concentration appears to have stabilized in recent years. The international treaty regime to reduce the anthropogenic impact on stratospheric ozone is widely considered an example of a successful effort to protect the global commons. In contrast, international efforts to reduce greenhouse gas concentrations have not yet had an impact.

Knowledge from an emerging science of human–environment interactions, sometimes called human ecology or the 'second environmental science',[26,27] is revealing which characteristics of institutions facilitate and which undermine sustainable

Figure 5.2 *Atmospheric concentration of* CO_2 *(solid line, right scale) and three principal ODS (dashed line, left scale). The ODS are chlorofluorocarbons (CFCs) 11, 12 and 113 and were weighted based on their ozone-depleting potential*[168]

use of environmental resources under particular conditions.[6,28] We know most about small-scale ecologies and institutions whose many successes and failures have been studied for years. Researchers are now developing a knowledge base for broader-scale systems. In this chapter, we address what science has learned about governing the commons, how adaptive governance can be implemented and why it is always a struggle.[29]

Why a Struggle?

Devising ways to sustain the Earth's ability to support diverse life, including a reasonable quality of life for humans, involves making tough decisions under uncertainty, complexity and substantial biophysical constraints as well as conflicting human values and interests (Box 5.1). Devising effective governance systems is akin to a co-evolutionary race. A set of rules crafted to fit one set of socio-ecological conditions can erode as social, economic and technological developments increase the potential for human damage to ecosystems and even to the biosphere itself. Furthermore, humans devise ways of evading governance rules. Thus, successful commons governance requires that rules evolve.

Effective commons governance is easier to achieve when (i) the resources and use of the resources by humans can be monitored, and the information can be verified and understood at relatively low cost (e.g. trees are easier to monitor than fish, and lakes are easier to monitor than rivers);[30] (ii) rates of change in resources, resource-user populations, technology, and economic and social conditions are

Box 5.1 *Fish moved by warming waters*

Mason Inman

Climate change has fish populations on the move. In Europe's intensively fished North Sea, the warming waters over the past quarter-century have driven fish populations northward and deeper, according to a study by conservation ecologist John D. Reynolds of the University of East Anglia in Norwich, UK, and his colleagues. Such warming could hamper the revival of overfished species and disrupt ecosystems, they assert. The warming is expected to continue in the North Sea, and although fish species living to the south will likely move north and replace departing ones, the forecast for the region's fisheries will depend on whether the species that succeed are marketable.

'This is another clear indication that warming is playing a role' in ocean ecosystems, says physical oceanographer Ken Drinkwater of the Institute of Marine Research in Bergen, Norway. Although there have been many studies looking at the effects of climate change on marine species, 'no one has looked in detail at changes in distributions of commercial and noncommercial species', says fish biologist Paul Hart of the University of Leicester in the UK. Similar climate-induced shifts in fish populations, he adds, might happen in other temperate seas, including those around Europe and much of the US.

The study used extensive records of fishing catches made by research vessels between 1977 and 2001, a period during which the North Sea's waters warmed by 1°C at the sea floor. Reynolds's team cast a wide net, compiling data on the sea's 36 most common bottom-dwelling fish. They found that two-thirds of the populations moved toward cooler waters – either going north or to deeper waters, or both. 'We saw shifts in both commercial and noncommercial species, and across a broad set of species', says conservation ecologist Allison Perry of the University of East Anglia. The fish species whose distribution have shifted tend to be smaller and mature earlier, she and her colleagues noted.

moderate;[31–33] (iii) communities maintain frequent face-to-face communication and dense social networks – sometimes called social capital – that increase the potential for trust, allow people to express and see emotional reactions to distrust, and lower the cost of monitoring behaviour and inducing rule compliance;[34–37] (iv) outsiders can be excluded at relatively low cost from using the resource (new entrants add to the harvesting pressure and typically lack understanding of the rules); and (v) users support effective monitoring and rule enforcement.[38–40] Few settings in the world are characterized by all of these conditions. The challenge is to devise institutional arrangements that help to establish such conditions or, as we discuss below, meet the main challenges of governance in the absence of ideal conditions.[6,41,42]

Selective Pressures

Many subsistence societies present favourable conditions for the evolution of effective self-governing resource institutions.[13] There are hundreds of documented examples of long-term sustainable resource use in such communities as well as in more economically advanced communities with effective, local, self-governing rights, but there are also many failures.[6,11,43–45] As human communities have expanded, the selective pressures on environmental governance institutions increasingly have come from outside influences. Commerce has become regional, national and global, and institutions at all of these levels have been created to enable and regulate trade, transportation, competition and conflict.[46,47] These institutions shape environmental impact, even if they are not designed with that intent. They also provide mechanisms for environmental governance (e.g. national laws) and part of the social context for local efforts at environmental governance. Broader-scale governance may authorize local control, help it, hinder it or override it.[48–53] Now, every local place is strongly influenced by global dynamics.[49,54–58]

The most important contemporary environmental challenges involve systems that are intrinsically global (e.g. climate change) or are tightly linked to global pressures (e.g. timber production for the world market) and that require governance at levels from the global all the way down to the local.[49,59,60] These situations often feature environmental outcomes spatially distant from their causes and hard-to-monitor, broader-scale economic incentives that may not be closely aligned with the condition of local ecosystems. Also, differences in power within user groups or across scales allow some to ignore rules of commons use or to reshape the rules in their own interest, such as when global markets reshape demand for local resources (e.g. forests) in ways that swamp the ability of locally evolved institutions to regulate their use.[61–63]

The store of governance tools and ways to modify and combine them is far greater than often is recognized.[6,64–66] Global and national environmental policy frequently ignores community-based governance and traditional tools, such as informal communication and sanctioning, but these tools can have significant impact.[64,67] Further, no single, broad type of ownership – government, private or community – uniformly succeeds or fails to halt major resource deterioration, as shown for forests in multiple countries.[68]

Requirements of Adaptive Governance in Complex Systems

Providing information

Environmental governance depends on good, trustworthy information about stocks, flows and processes within the resource systems being governed, as well as about the human–environment interactions that affect those systems. This information must be congruent in scale with environmental events and decisions.[49,69] Highly aggregated information may ignore or average out local information that is important in identifying future problems and developing solutions.

For example, in 2002, a moratorium on all fishing for northern cod was declared by the Canadian government after a collapse of this valuable fishery. An earlier near-collapse had led Canada to declare a 200-mile zone of exclusive fisheries jurisdiction in 1977.[70,71] There was considerable optimism during the 1980s that the stocks, as estimated by fishery scientists, were rebuilding. Consequently, generous total catch limits were established for northern cod and other groundfish, the number of licensed fishers was allowed to increase considerably and substantial government subsidies were allocated for new vessels.[72] What went wrong? There were a variety of information-related problems, including that fisheries managers (i) treated all northern cod as a single stock instead of recognizing distinct populations with different characteristics, (ii) ignored the variability of year classes of northern cod, (iii) focused on offshore-fishery landing data rather than inshore data to 'tune' the stock assessment, and (iv) ignored inshore fishers who were catching ever-smaller fish and doubted the validity of stock assessments.[72–74] This experience illustrates the need to collect and model both local and aggregated information about resource conditions and to use it in making policy at the appropriate scales.

Information also must be congruent with decision makers' needs in terms of timing, content and form of presentation.[75–77] Informational systems that simultaneously meet high scientific standards and serve ongoing needs of decision makers and users are particularly useful. Information must not overload the capacity of users to assimilate it. Systems that adequately characterize environmental conditions or human activities with summary indicators – such as prices for products or emission permits, or certification of good environmental performance – can provide valuable signals as long as they are attentive to local as well as aggregate conditions.[78–80]

Effective governance requires not only factual information about the state of the environment and human actions but also information about uncertainty and values. Scientific understanding of coupled human–biophysical systems will always be uncertain because of inherent unpredictability in the systems and because the science is never complete.[81] Decision makers need information that characterizes the types and magnitudes of this uncertainty, as well as the nature and extent of scientific ignorance and disagreement.[82] Also, because every environmental decision requires trade-offs, knowledge is needed about individual and social values and about the effects of decisions on various valued outcomes. For many environmental systems, local and easily captured values (e.g. the market value of lumber) have to be balanced against global, diffuse and hard-to-capture values (e.g. biodiversity and the capability of humans and ecosystems to adapt to unexpected events). Finding ways to measure and monitor the outcomes for such varied values in the face of globalization is a major informational challenge for governance.

Dealing with conflict

Sharp differences in power and in values across interested parties make conflict inherent in environmental choices. Indeed, conflict resolution may be as important a motivation for designing resource institutions as is concern with the resources themselves.[83] People bring varying perspectives, interests and fundamental philosophies to problems of environmental governance;[76,84–86] their conflicts, if they do not escalate to the point of dysfunction, can spark learning and change.[87,88]

For example, a broadly participatory process was used to examine alternative strategies for regulating the Mississippi River and its tributaries.[89] A dynamic model was constructed with continuous input by the Corps of Engineers, the Fish and Wildlife Service, local landowners, environmental groups and academics from multiple disciplines. After extensive model development and testing against past historical data, most stakeholders had high confidence in the explanatory power of the model. Consensus was reached over alternative governance options, and the resulting policies generated far less conflict than had existed at the outset.[90]

Delegating authority to environmental ministries does not always resolve conflicts satisfactorily, so governments are experimenting with various governance approaches to complement managerial ones. These range from ballots and polls, where engagement is passive and participants interact minimally, to adversarial processes that allow parties to redress grievances through formal legal procedures. They also include various experiments with intense interaction and deliberation aimed at negotiating decisions or allowing parties in potential conflict to provide structured input to them through participatory processes.[91–95]

Inducing rule compliance

Effective governance requires that the rules of resource use are generally followed, with reasonable standards for tolerating modest violations. It is generally most effective to impose modest sanctions on first offenders and gradually increase the severity of sanctions for those who do not learn from their first or second encounter.[40,96] Community-based institutions often use informal strategies for achieving compliance that rely on participants' commitment to rules and subtle social sanctions. Whether enforcement mechanisms are formal or informal, those who impose them must be seen as effective and legitimate by resource users or resistance and evasion will overwhelm the commons governance strategy.

Much environmental regulation in complex societies has been 'command and control'. Governments require or prohibit specific actions or technologies, with fines or jail terms possible to punish rule breakers. If sufficient resources are made available for monitoring and enforcement, such approaches are effective. But when governments lack the will or resources to protect 'protected areas' such as parks,[97–99] when major environmental damage comes from hard-to-detect 'nonpoint sources', and when the need is to encourage innovation in behaviours or technologies rather than to require or prohibit familiar ones, command and control approaches are less effective. They are also economically inefficient in many circumstances.[100–102]

Financial instruments can provide incentives to achieve compliance with environmental rules. In recent years, market-based systems of tradable environmental allowances (TEAs) that define a limit to environmental withdrawals or emissions and permit free trade of allocated allowances under those limits have become popular.[78,101,103] TEAs are one of the bases for the Kyoto agreement on climate change.

Economic theory and experience in some settings suggest that these mechanisms have substantial advantages over command and control.[104–107] TEAs have exhibited good environmental performance and economic efficiency in the US Sulfur Dioxide Allowance Market intended to reduce the prevalence of acid rain[108,109] and the Lead Phasedown Program aimed at reducing the level of lead emissions.[110] Crucial variables that differentiate these highly successful programmes from less successful ones, such as chlorofluorocarbon production quota trading and the early EPA emission trading programmes, include (i) the level of predictability of the stocks and flows, (ii) the number of users or producers who are regulated, (iii) the heterogeneity of the regulated users, and (iv) dearly defined and fully exchangeable permits.[111]

TEAs, like all institutional arrangements, have notable limitations. TEA regimes tend to leave unprotected those resources not specifically covered by trading rules. For example, fish species caught as by-catch are often not covered.[112] These regimes also tend to suffer when monitoring is difficult. For example, under the Kyoto Protocol, the question of whether geologically sequestered carbon will remain sequestered is difficult to answer. Problems can also occur with the initial allocation of allowances, especially when historic users, who may be called on to change their behaviour most, have disproportionate power over allocation decisions.[78,113] TEAs and community-based systems appear to have opposite strengths and weaknesses,[113] suggesting that institutions that combine aspects of both systems may work better than either approach alone. For example, the fisheries tradable permit system in New Zealand has added co-management institutions to complement the market institutions.[103,114]

Voluntary approaches and those based on information disclosure have only begun to receive careful scientific attention as supplements to other tools.[64,79,115–118] Success appears to depend on the existence of incentives that benefit leaders in volunteering over laggards and on the simultaneous use of other strategies, particularly ones that create incentives for compliance.[79,118–120] Difficulties of sanctioning pose major problems for international agreements.[121–123]

Providing infrastructure

The importance of physical and technological infrastructure is often ignored. Infrastructure, including technology, determines the degree to which a commons can be exploited. The extent and quality of water systems determine how they distribute water, for example, and fishing technology has a decisive influence on the size of the catch. Infrastructure also determines the extent to which waste can be reduced in resource use, and the degree to which resource conditions and the behaviour of human users can be effectively monitored. Indeed, the ability to choose institutional arrangements depends in part on infrastructure. In the absence of barbed-wire fences, for example, enforcing private property rights on grazing lands is expensive, but with barbed wire fences, it is relatively cheap.[124]

Effective communication and transportation technologies are also of immense importance. Fishers who observe an unauthorized boat or harvesting technology can use a radio or cellular phone to alert others to illegal actions.[125] Infrastructure also affects the links between local commons and regional and global systems. Good roads can provide food in bad times but can also open local resources to global markets, creating demand for resources that cannot be used locally.[126] Institutional infrastructure is also important, including research, social capital and multi-level rules, to coordinate between local and broader levels of governance.[49,127,128]

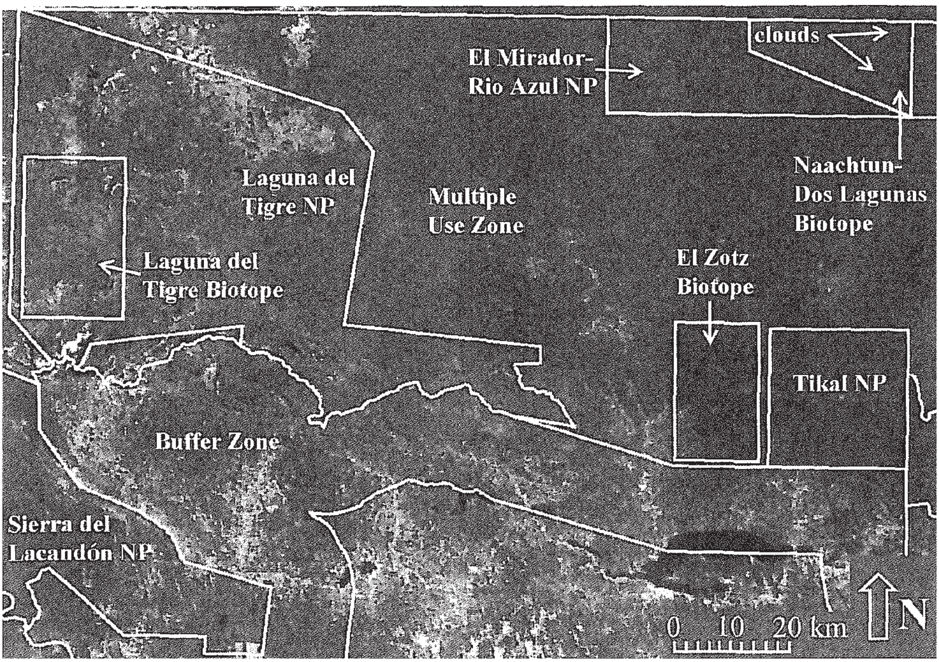
Be prepared for change

Institutions must be designed to allow for adaptation because some current understanding is likely to be wrong, the required level of organization can shift, and biophysical and social systems change. Fixed rules are likely to fail because they place too much confidence in the current state of knowledge, whereas systems that guard against the low-probability, high-consequence possibilities and allow for change may be suboptimal in the short run but prove wiser in the long run. This is a principal lesson of adaptive governance research.[29,32,129]

An Illustration of the Challenge of Inducing Rule Compliance

Meeting these requirements is always a challenge. We illustrate by focusing on the problem of inducing rule compliance and comparing the experience of four national parks, three different biological communities and a buffer zone contained within a single, large and very famous biosphere reserve – the Maya Biosphere Reserve (MBR) in Guatemala.[130] MBR (Figure 5.3) was created in 1990 by government decree to protect the remaining areas of pristine ecosystems in northern Guatemala.[131] The region saw a marked advance of the agricultural frontier in the 1980s resulting from an aggressive policy of the central government to provide land to farmers from the south.[132] MBR occupies over 21,000km^2, equivalent to 19 per cent of the Guatemalan territory, and represents the second-largest tract of tropical forest in the Western Hemisphere, after the Amazon.[133] Much of the territory within the reserve has been seriously deforested and converted to agriculture and other uses. Figure 5.3 shows examples of several governance strategies and outcomes within MBR,[134] but we concentrate here on two protected areas that have interesting institutional differences.

Tikal National Park is one of few protected areas in Guatemala to receive the full support of the government. The revenue from entry fees paid by tourists covers the entire budget for the park plus a surplus that goes to the Ministry of Culture and Sports. Directors of the park are held accountable by high-level officials for the successful protection of this source of government revenue. The park has permanent administrative and support staff, paid guards and local residents hired to prevent forest fires. Although Tikal National Park is in better shape than many other parks,[135] it faces multiple threats, especially from bordering communities in the form of forest fires ignited to transform the land for agricultural and livestock purposes and illegal extraction of forest products.[136] The dark grey colour of the park in Figure 5.3 shows the areas of stable forest.



Source: Composite constructed by Glen Green, Edwin Castellanos and Victor Hugo Ramos.

Figure 5.3 *This figure shows land-cover change and the numerous zones of the Maya Biosphere Reserve in northern Guatemala. The composite shows a uniform, dark grey colour within Tikal, indicative of stable forest cover. El Mirador-Rio Azul National Park and Naachtun-Dos Laguna Biotope are also stable, due to inaccessibility. The other four potected areas have experienced extensive inroads of deforestation shown in light grey and white. Official designation as a protected area is not sufficient unless substantial investments are made in maintaining and enforcing boundaries*

Laguna del Tigre National Park and Biotope are managed by two different conservation agencies and include the largest protected wetland in Central America. The principal threats are human settlement and immigration, encroaching agriculture and livestock, oil prospecting and drilling, construction of roads and other infrastructures, and lawlessness (e.g. intentional setting of forest fires and drug trafficking and plantations). Like Tikal, Laguna del Tigre has been designated for the highest possible level of government protection. However, land speculation inside and outside the park and biotope, fuelled by cattle ranchers, corrupt politicians, and other officials, has pushed illegal settlers deeper into the reserve, where they clear tree cover to establish new agricultural plots and homesteads. Numerous light gray patches within the park and biotope in Figure 5.3 reveal forest clearing.[137] Oversight in Laguna del Tigre has been weak. The small and underpaid group of park rangers is unable to enforce the mandates assigned to them to protect the park from human settlements, illegal harvesting and forest fires, and to sanction those who do not comply. It has not been unusual for people accused of violating conservation laws to threaten park officials to the point where the latter are afraid to enforce the law.

The Guatemalan cases illustrate that legally protecting threatened areas does not ensure rule compliance, especially when non-compliance is easy or profitable. Further illustrations of the roles of institutions in forest protection are discussed in *Science* supplemental online materials[68] and in a new book.[138]

Strategies for Meeting the Requirements of Adaptive Governance

The general principles for robust governance institutions for localized resources (Figure 5.4) are well established as a result of multiple empirical studies.[13,40,139–148] Many of these also appear to be applicable to regional and global resources,[149] although they are less well tested at those levels. Three of them seem to be particularly relevant for problems at broader scales.

Analytic deliberation

Well-structured dialogue involving scientists, resource users and interested publics, and informed by analysis of key information about environmental and human–environment systems, appears critical. Such analytic deliberation[76,150–152] provides improved information and the trust in it that is essential for information to be used effectively, builds social capital, and can allow for change and deal with inevitable conflicts well enough to produce consensus on governance rules. The negotiated 1994 US regulation on disinfectant by-products in water that reached an interim consensus, including a decision to collect new information and reconsider the rule on that basis,[76] is an excellent example of this approach.

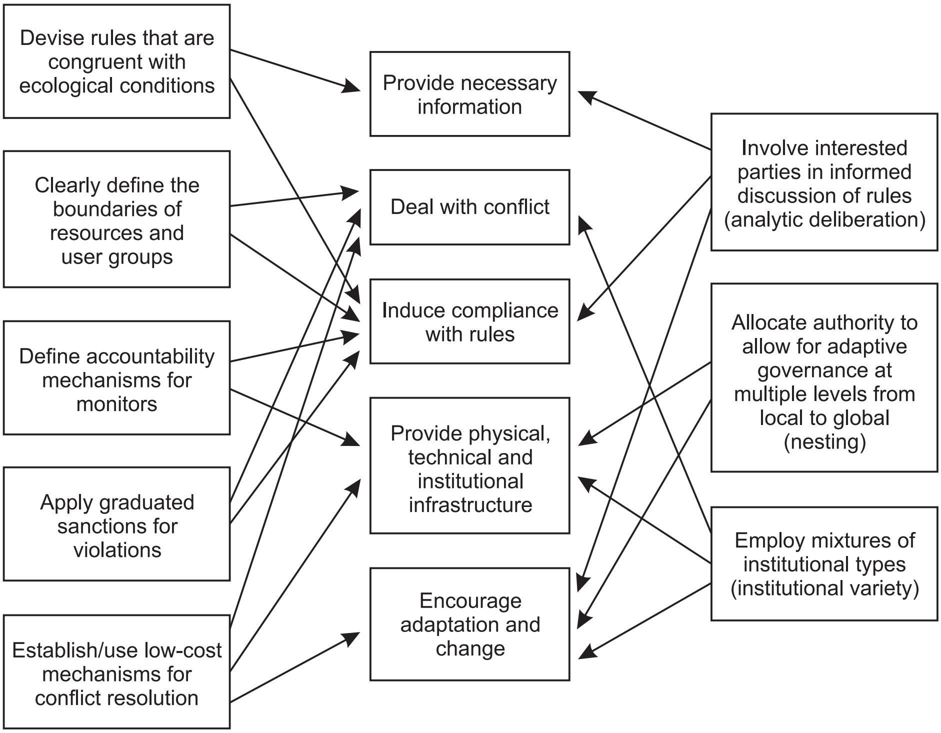


Figure 5.4 *General principles for robust governance of environmental resources (left and right columns) and the governance requirements they help meet (centre column).*[13,170] *Each principle is relevant for meeting several requirements. Arrows indicate some of the most likely connections between principles and requirements. Principles in the right column may be particularly relevant for global and regional problems*

Nesting

Institutional arrangements must be complex, redundant and nested in many layers.[33,153,154] Simple strategies for governing the world's resources that rely exclusively on imposed markets or one-level, centralized command and control and that eliminate apparent redundancies in the name of efficiency have been tried and have failed. Catastrophic failures often have resulted when central governments have exerted sole authority over resources. Examples include the massive environmental degradation and impoverishment of local people in Indonesian Borneo;[97] the increased rate of loss and fragmentation of high-quality habitat that occurred after creating the Wolong Nature Reserve in China;[155] and the closing of the northern cod fishery along the eastern coast of Canada, which is partly attributable to the excessive quotas granted by the Canadian government.[72] Governance should employ mixtures of institutional types (e.g. government bureaus as well as markets and community self-governance) that employ a variety of decision rules (about when and what resources should be harvested by whom) to change incentives, increase information, monitor use and induce compliance.[6,64,119] Innovative rule evaders can have more trouble with a multiplicity of rules than with a single type of rule.

Conclusion

Is it possible to govern such critical commons as the oceans and the climate? We remain guardedly optimistic. Thirty-five years ago it seemed that the 'tragedy of the commons' was inevitable everywhere not owned privately or by a government. Systematic multidisciplinary research has, however, shown that a wide diversity of adaptive governance systems have been effective stewards of many resources. Sustained research coupled with an explicit view of national and international policies as experiments can yield the scientific knowledge necessary to design appropriate adaptive institutions.

Sound science is necessary for commons governance, but not sufficient. Too many strategies for governance of local commons are designed in capital cities or by donor agencies in ignorance of the state of the science and local conditions. The results are often tragic, but at least these tragedies are local. As the human footprint on Earth enlarges,[156] humanity is challenged to develop and deploy understanding of broad-scale commons governance quickly enough to avoid the broad-scale tragedies that will otherwise ensue.[172]

29 We refer to *adaptive governance* rather than *adaptive management* (*32, 129*) because the idea of governance conveys the difficulty of control, the need to proceed in the face of substantial uncertainty, and the importance of dealing with diversity and reconciling conflict among people and groups who differ in values, interests, perspectives, power and the kinds of information they bring to situations (*150, 160–163*). Effective environmental governance requires an understanding of both environmental systems and human–environment interactions (*27, 84, 164, 165*).

137 A recent report in *U.S. News & World Report (171)* strongly verifies the satellite data and illuminates the causes of continuing deforestation in the Laguna del Tigre National Park since the most recent satellite image in Figure 5.3, taken in 2000. The reporter wrote: 'Since the end of the civil war in 1996 desperately poor farmers and rich cattle ranchers have been pouring into this vast, virgin rain forest. In the past five years, more than 5000 homesteaders have illegally built homes and set fires to clear the land for corn and cattle. In 2003, [Dr David] Freidel's first year of excavation here [at the "El Peru" archaeological site], the flames got so close – about 2 miles away – that he had to pull workers off the ruins to dig fire lines to save the camp… The ground fires have so far burned an estimated 40 per cent of the park, which is supposed to protect a lake that is one of the most important wetlands in the world' (online at www.usnews.com/usnews/culture/articles/050627/27profile_3.htm).

Words and Ideas: Commitment, Continuity and Irreversibility

R. Chambers

All words are pegs to hang ideas on (Henry Ward Beecher, 1887).

Part 1 presents writing on settlement schemes in tropical Africa from the late 1960s and early 1970s. Part 2 reviews subsequent developments with settlement schemes, and then explores and develops wider contemporary meanings, relevance and applications for three words and ideas from the earlier experience: commitment, continuity and irreversibility.

Part I: Learning from Experience

In the 1950s and 1960s, settlement schemes were conspicuous in tropical Africa. Many of them were politically committing and effectively irreversible. Once settlers had been introduced they were difficult to abandon. Schemes considered failures became robust dependent survivors. Many arguments could be mustered to justify continuing support, although this was often at high financial cost to governments. The Perkerra Irrigation Scheme in Kenya was one such project which by almost any criteria should never have been started, and once started, not continued. It performed disastrously but became increasingly difficult to abandon. In project appraisal, the political irreversibility of commitment is a neglected aspect of risk, and varies by type of project.

Introduction: Settlement schemes in tropical Africa (2004)

In the sub-Saharan Africa of decolonization and early national independence, much prominence was given to agricultural settlement schemes. They seemed to promise win–win solutions to political demands, perceived pressures of population, and the need to produce more from the land. With many origins, taking many forms, having high political priority, and being bounded and visible, they were attractive to

Reprinted from Chambers R. 2005. Words and ideas: Commitment, continuity and irreversibility. In Chambers R. *Ideas for Development*, Earthscan, London.

researchers. I was one of those who succumbed to the temptations they presented. I started my research on the fragile and vulnerable Perkerra Irrigation Settlement in Kenya, and then concentrated on its stronger sibling, Mwea. The Mwea Irrigation Settlement had several advantages. It was by most criteria more successful; it had a stable water supply and in irrigated rice a reliable crop and a protected market; it was better organized; it had a high profile and was frequently visited, being a convenient distance from Nairobi for VIPs;[1] and, for the indolent PhD student it had the advantage of being well documented, with time series tables which could (I hasten to add, with due acknowledgement) be transposed easily to make a thesis look good, at least to any examiner too pressed for time to look deeply. Many researchers were attracted to Mwea, and the managers were so interested and articulate that we were able to combine to produce a book with 13 chapters and 529 pages (Chambers and Moris, 1973).[2]

In parallel, numerous studies of settlement schemes were undertaken in other countries, especially Sudan, Zimbabwe (Southern Rhodesia as it was), Zambia (Northern Rhodesia as it was), Tanzania, Uganda, Nigeria and Ghana. These provided a wonderful collection for comparisons. Much of what was learnt is now of mainly historical interest. However, analysis at the time pointed to three neglected angles or themes which were important then and remain important and still relatively neglected: commitment, continuity and irreversibility. The two extracts of studies from this period, which follow, raise practical questions not only about projects, but also about policies and programmes promoted and pursued by lenders, donors and governments in the 2000s.

Conclusions from *Settlement Schemes in Tropical Africa* (1969)

Risks and irreversibility of commitment[3]

A neglected aspect of evaluation, which has far wider application than merely to settlement schemes, concerns the relationship between risks and irreversibility of commitment.

Settlement schemes, especially those that are more complex in system and costly in capital, are high-risk undertakings. They share with non-settlement approaches to agricultural development the uncertainties of innovations, weather, pests and markets, and the disruptions of rapid turnovers in senior staff. In addition, however, they have to face other serious risks and difficulties which do not have to be borne in non-settlement situations. The land on which settlement takes place may be available for settlement for the simple reason that it is marginal or unsuitable for cultivation. The locations of many settlement schemes, often with poor communications and far from the services of urban centres, raise costs and the difficulties of management. There is a danger that both organizational and productive effectiveness will be restrained by the inbuilt incompatibilities of complex schemes, by the cancelling out of managerial and settler efforts, in the games of enforcing and beating the system. Moreover, adaptations of schemes to ensure the continued presence and participation of settlers may have to be made through increased payouts or through services which, at best, reduce revenue to government and, at worst, add to a loss. In addition, where government withdrawal is intended, there is a high risk that it will take longer than expected. At the point at which implementation of a settlement scheme or programme is considered, all these factors, all of them implying economic risks, should be weighed.

But these risks do not present the complete picture. Wherever a government starts a programme or project the actual risks are compounded by the extent to which the commitment to maintain the programme or project is irreversible. The process of commitment can be lengthy, subtle and insidious. It begins with an opportunity and a vision. These may arise from a disturbance in the relationships of men[4] and land, or the perception of unoccupied land: the Mwea (in Kenya), inviting development after the Kenya Land Commission's recommendations; the bush of South Busoga (in Uganda) after its evacuation in the first decade of this century; the narrow strip of uncultivated land on the edge of the Rift Valley at Upper Kitete (in Tanzania); the cleared bush of Kongwa, Urambo and Nachingwea after the Groundnut Scheme fiasco (in Tanzania). Or the opportunity may be provided by a resettlement operation which presents a captive population which can be directed into a new agricultural system: the displacement of Halfawis by the Aswan Dam, (in Sudan) was exploited through resettlement on the controlled irrigation scheme at Khasm-el-Girba; and the evacuees from the Volta Lake were thought to provide 'a unique opportunity to wean an appreciable proportion of Ghana's farmers from the wasteful, fragmented, and shifting system of agriculture to a settled and improved pattern of farming'.[5]

The opportunity attracts and nourishes the idea of a scheme. In such conditions a personal commitment can develop in a man of vision like Simon Alvord in Rhodesia or Chief Akin Deko in Nigeria. Funds are obtained for surveys: the surveys that are carried out are themselves committing. Where their findings are marginal, as was the United Nations Special Fund survey of the proposed Tana Irrigation Project in Kenya,[6] further investigations are called for. It becomes increasingly difficult to turn back. Once funds have been made available for a substantive scheme, the successive activities of planning, construction, settlement and production draw after them deeper and deeper personal, departmental and political commitments. The establishment of settlers sets a seal on commitment at a higher level, making abandonment extremely difficult and the use of protective political arguments extremely easy. The full repertoire of defences to ensure scheme or programme survival can now be brought into play. Moreover, officials and politicians in circumstances such as these may regard government funds as fair game, as an ecological feature to be exploited much as a river might be tapped for irrigation water. The risks involved in the original initiation of a project are now more obvious: risks not merely that it would fail, but that having failed it would survive as a parasite that could not be shaken off or killed.

The issues involved in a decision to terminate a scheme are, of course, not simple. Those responsible for the decisions may not even agree about whether the amount of money already sunk in a project is a relevant consideration. Attitudes and ideas are sufficiently confused and contradictory for irrational elements to have free play. It is extremely difficult, for example, to see the large quantities of fine onions grown on the Perkerra Scheme in Kenya, and to compare the green irrigated fields with the surrounding desert, and at the same time to sustain a conviction that the scheme should be abandoned. Running water through channels and onto dry land, growing abundant crops where there was only bare soil and barren bush before, and enabling people to enjoy a level of prosperity they have never previously known, appear inherently and incontrovertibly good. It is Isaiah's vision:

> The wilderness and the solitary place shall be glad for them; and the desert shall rejoice, and blossom as the rose (The Bible).

To suggest closure seems ignoble and destructive, an affront to the aspirations and achievements of the human spirit. If a neutral visitor can have this feeling, it may be expected all the more in those whose lives and work are bound up in a scheme. Yet the power of this emotion multiplies the risks of starting projects of this sort through making it exceptionally difficult to close them down however uneconomic they may prove.

There is, indeed, a strain of Utopianism in most complex settlement schemes. Often there is an idealized view of the human situation that settlement will create. In colonial times this was often the stabilized African, fixed and controlled on a piece of land. Since independence, it has varied: in West Africa it has been an urban farmer; in Kenya, a sturdy yeoman; in Tanzania, a cooperative worker. Another Utopian aspect is the frequency with which stresses and breakdowns are not anticipated: as Apthorpe (1966, p23) has pointed out, provision is often lacking either for failure of the social system or for mechanical repairs. Again, it is very common for the targets for land preparation, settlement, production and withdrawal to be wildly optimistic and for achievements to fall far short of them. These features are partly explicable in terms of the self-delusion of men who are transported by a vision. When an ideal is pursued by a whole community, as in some communal economy schemes, it may make a scheme feasible through the sacrifices the participants are prepared to accept; but when the vision is only in the mind of the initiator, as it has been with most complex settlement schemes, the effects are often a sequence of unrealistic estimates, uneconomic measures and personal commitments which comprise part of the risks of the project.

Resisting temptation[7]

Since all these disadvantages have applied in the past they can be expected to continue to apply in the future, and should be taken into account in assessing proposals for settlement schemes and similar agricultural projects. It is not enough to carry out evaluations[8] which consider only those economic factors which can be quantified; it is necessary also to include administrative factors and the probable motivations and behaviour of the actors involved. Allowance has to be made, for example, for the expected patterns of settler and managerial behaviour, for departmentalism, for staff discontinuities and for the inbuilt incompatibilities of scheme systems. Moreover, comparisons with alternative approaches to agricultural development should take into account the high opportunity costs of trained staff and the expected ease or difficulty of abandoning a project or programme if it proves uneconomic. When all this is done the case against high capital and complex settlement schemes becomes stronger than when only conventional cost–benefit criteria are used. While this does not mean that such schemes should be ruled out altogether, it does mean that they should be approached with greater care and understanding.

Where a settlement scheme is unavoidable, and where there is a choice of type to be adopted, there is much to be said on organizational grounds for the simplest type of scheme that is compatible with the circumstances of settlement. The simpler approaches are relatively undemanding of scarce administrative and technical capacity, and engage it for shorter periods. They involve relatively low risk and low commitment. Moreover, schemes with individual holdings exploit the drives of property ownership and individual incentive which can make productive the labour which is the most abundant unused resource in much of the third world. The simpler schemes also require intermediate levels of organization corresponding with the intermediate technology which may also be appropriate. If the beginning is ambitious, a complex organization may collapse and find equilibrium at a lower level; but if the beginning is modest, a more complex technology and organization can grow up organically and gradually. For example, the tractors appearing on Chesa in Rhodesia and on the Kenya Million-Acre Schemes as a result of settler initiative represent a self-sustaining upward movement in which productivity may increase without heavy government investment or commitment. If such developments are to be possible, it is important that advisory and technical services be available when needed, and even more important that the system of land tenure adopted should allow for future flexibility in farm size. Given such flexibility, it is usually safer and sounder to develop piecemeal from an existing base, whether this is farmers already on their land or settlers, already on a scheme, than to attempt radical transformation in one long step.

Settlement schemes, particularly those which are complex in system, will remain temptations. Because of their creative possibilities, they will continue to find energetic and enthusiastic sponsors. Because of their visibility, clear boundaries, organizational coherence and Utopian overtones, they will no doubt continue to attract successive colonization – by administrators who negotiate their emergence, constructors who build them, agriculturalists who manage them, settlers who populate them, and in their wake foreign aid personnel and research students[9] in various capacities – all of whom will find satisfaction in occupying a bounded and identifiable territory. What is vital is not that such schemes should be avoided on principle, but that those who act in these situations should appreciate what is happening. It is especially important that those who make development decisions should understand themselves well enough to be able to compensate in their acts of judgement for the strong pull of the psychological attractions of such schemes, and should be able to see clearly the risks they entail and the benefits that might accrue from alternative uses of the resources involved. Exceptional restraint and imagination are needed among politicians and civil servants if the lure of the big scheme is to be neutralized so that a balanced and realistic assessment can be made. Perhaps it is fortunate that so many African politicians and civil servants possess and farm their own land. While this may be a distraction it may also satisfy desires for property and territory, so that they are less prone than their expatriate predecessors to seek such satisfaction through their work. It may in the long term enable them to take more balanced views of policy and to appreciate more fully the alternatives that exist. Certainly it is important to recognize that the choices are neither clearcut nor easy. It is not enough, as was done in Kenya before independence (Government of Kenya, 1962, p1), to quote Gulliver's report of the views of the King of Brobdignag:

> And he gave it for his opinion, that whoever could make two ears of corn or two blades of grass to grow upon a spot of ground where only one grew before, would deserve better of mankind, and do more essential service to his country than the whole race of politicians put together (Swift, 1726, Chapter 7).

For the issues are less simple: they include whether, with the same resources, many more ears of corn, or many more blades of grass, might not be grown in other ways or in other places; and whether those politicians and civil servants who make major policy decisions have the freedom, the insight and the courage to choose those other ways or places, however unspectacular they may be.

Learning from project pathology: The case of Perkerra[10]

Introduction (2004)

The Perkerra Irrigation Scheme in Kenya was launched precipitously in 1952 during the Mau Mau Emergency. It was known that there had been a proposal for irrigation on the Perkerra river, but the 1936 exploratory report could not be found. Detainees were placed in camps on the site and employed on road building and preparing works and fields for irrigation. From the start, capital and recurrent costs were high and revenue negligible. Tenants were settled but many left. Areas irrigated consistently fell far short of those targeted. Agricultural and marketing problems were intractable. In 1959 with just over 100 settler families, it was decided to close the scheme down. The decision was then reversed and changed to running on a care and maintenance basis for three years. By 1962 closure had become more difficult. The scheme was instead expanded to try to make it less of a recurrent burden on government. By 1967, with over 500 settler families, commitment had become even harder to reverse, and the scheme continued, with cross-subsidies from an economically successful sister scheme in another Province, the Mwea Irrigation Settlement.

Lessons from Perkerra (1973)

Many lessons could be culled from the Perkerra experience. Only some of the more obvious and important will be mentioned here.

In the first place, the high costs and risks of hasty development with inadequate surveys are abundantly clear. To embark upon a major irrigation project with little knowledge of river flows and with what limited knowledge there is indicating unreliability; without any assurance that a cash crop can be grown and marketed; without experience of tenants' performance; and without any pilot project – these are to court disaster. Moreover, one effect of such ignorance is to encourage over-investment in unprofitable directions which have then to be abandoned: the 430 acres of basin irrigation which were overrun by nutgrass, and the extensive cultivation, before adequate trials had been carried out, of tomatoes, groundnuts and even onions. When, as has occurred at Perkerra, most of the experimental work is carried out not on a research station but with tenants on their plots the risks of failure are multiplied by the dangers of tenant dissatisfaction, of loss of confidence in the management, of absenteeism and ultimately of permanent departure from the scheme.

Second, when a complex project requiring a favourable coincidence of several interdependent factors begins to run into trouble, difficulties tend to compound one another. On Perkerra, lack of water has sometimes limited the acreage that can be irrigated, in turn limiting returns to tenants and revenue to the scheme, increasing the dependence of the scheme on subsidy and aggravating the problems of tenant management. Unstable onion prices have affected tenant and staff morale as well as revenue. Evictions and other disciplinary measures to secure effective tenant performance may be partly self-defeating by reducing the tenants' sense of security on a scheme and encouraging them to spend more time and energy on their off-scheme activities. Such chain reactions as these make heavy demands both on managerial skill and patience and on the financial resources of a parent organization. Where a scheme has, like Perkerra, a generally unfavourable physical environment and narrow technical limits of tolerance, able management may reduce or cushion some of these reactions but is unlikely always to overcome them. In these circumstances, financial support of various forms becomes the variable that is easiest to manipulate, with the result that a scheme is maintained but at a heavy cost to the rest of the economy.

A third lesson emerges from the process of creeping commitment to the scheme, starting with the first ideas of replacing the indigenous irrigation which had been destroyed (by a flood in 1919), leading to preliminary surveys and then to a situation in which the idea of irrigation was at large and ready to be seized on whenever an opportunity presented itself. There was never any meeting or moment at which a decision to implement the Scheme was clearly taken. Even the siting of the camp at Marigat was only partly associated with the possibility of irrigation. But the very presence and use of the labour; the posting in of staff; the allocation of funds; the physical developments such as building the camp, construction of the weir, and land preparation; the deepening enthusiasms of individual officials and the increasing involvement of departmental interests; the visits of VIPs to inspect progress; the selection, induction and management of tenants; the growing and marketing of crops – all these in multiple ways progressively secured the scheme as a permanent entity and strengthened its capacity to survive. It became increasingly difficult to close it down. To abandon the scheme would have meant to accept failure, to write off heavy government expenditure, and to have to resettle tenants, transfer staff and save a number of faces. It was always easier and involved less immediate acceptance of responsibility to allow the scheme to continue. The chance in 1962 when the tenants could have been resettled in the former European highlands was allowed to slip, and by 1968, with some 500 tenants to varying degrees dependent on the scheme, closure had become politically and humanly difficult even to contemplate.

A fourth observation is that the true costs of a project like Perkerra may usually be greater than their apparent costs. To evaluate any scheme is, of course, a complex operation with several quantifiable and many unquantifiable factors to be taken into account; and, to be sure, even with Perkerra there have been hidden benefits – learning on the part of the tenants, including their introduction to a cash economy; experience gained by government officials; investment of incomes generated by the scheme; indirect government revenue; and seasonal employment, among others. But schemes which are heavily committing in terms of capital expenditure, departmental and individual involvement, and political interest and support tend to receive a perverse protection: the levels of external support and of tolerance in evaluation vary inversely with their economic performance. Except in stringent economic evaluations, 'success' for a scheme like Perkerra is defined in less exacting terms than for an economically more viable scheme such as Mwea. Protective standards of assessment and hidden subsidies are easily combined to give a false impression of favourable economic performance. Moreover, a scheme such as Perkerra has to be evaluated not just in isolation but in terms of benefits forgone from alternative uses of the resources involved – especially capital, managerial competence and effort, and labour. Had the sum of over £500,000 and the human resources invested in Perkerra by 1968 been used in other ways, the results might have been substantial benefits instead of continuing indefinite liabilities.

These four lessons – the costs and risks of haste and ignorance; the compounding of problems in complex projects; the irreversibility of the creep of commitment; and the high true costs of poor projects – combine in a criterion applicable to choices in agricultural development. The Perkerra Irrigation Scheme, with its requirement from the start of complex and continuing organization involving government support, can be contrasted as a policy with the implications of an incident in the history of the scheme. In 1961 the manager noted that 'A tenant was given a sample of Taboran maize seed which ripened about four weeks earlier than the local variety and yielded at a rate of 11 bags per acre. The tenant concerned was besieged by others wanting seed to plant.' This was, of course, an event on an irrigation scheme, but the implications are wider and apply to non-irrigated agriculture. The contrast here is between on the one hand a major project like Perkerra which requires ongoing government involvement, and on the other programmes like the introduction of a new seed variety which can be one-shot efforts. In a major project the risks and liabilities are shouldered by government: if the project succeeds, government is obliged to continue to service and manage it; if it fails, it may prove politically and administratively impossible to abandon it. In the one-shot programme, however, the risks and liabilities are accepted by the individual farmers: if the innovation succeeds, it is propagated without further government intervention; if it fails, it is quickly and easily abandoned by the farmers without additional cost or administration for government.

There are, of course, a great many other considerations which bear on policy choices; but capital and administrative capacity are typically scarce resources to be used sparingly; and in choosing between alternative approaches to agricultural development there is a case, other things being equal, for preferring those which are cheap, simple, administration sparing and easy to withdraw from to those which are expensive, complex, administration intensive and committing.

It is not enough merely to be aware of these considerations; there must also be a climate and machinery in government to make sure that they are taken into account. In British colonial government in East Africa in the 1950s there was a relative absence of economic criteria in official thinking and a readiness to support the initiative of officers at the local level when they promoted projects. There was sympathetic backing in the Kenya central government for the vision and enthusiasm of the civil servants at provincial and district level who energetically launched the Perkerra Irrigation Scheme. Entrepreneurial capacity of the sort which they demonstrated is certainly an asset to a government, but as the Perkerra story shows it can be dangerous unless it is controlled. What is needed is a powerful and perceptive presence in governments which, while not stifling local initiatives, ensures that schemes as unpromising as Perkerra are never begun; for it is far easier to prevent a bad project than, once it has been started, to close it down.

Part 2: Developments, Concepts and Discourse (2004)

The legacy of Perkerra and its need for subsidies has continued into the 21st century. After the 1960s, agricultural settlement projects became less favoured in most parts of the world. Big dams and other projects were increasingly recognized to have high human costs in the many who were displaced, dispossessed and inadequately compensated. Champions within the World Bank and internationally networking activists made lenders, donors and, to a lesser degree, governments, more aware of human costs and more reluctant to fund dams and other projects which displaced people.

Commitment to projects and continuity of aid agency and developing country government staff, created conditions for innovation, learning and changes in practices and policies. In the 1990s, as aid agencies and governments shifted their priorities to *programmes and policy, there were human and ethical costs as projects were abandoned. With the new priority to influence policy so continuity, partnerships, relationships, understanding and trust became and remain more important than ever.*

Irreversibility is neglected in conventional economics compared to risk and uncertainty. The precautionary principle in environmental and other decision making recognizes irreversibility, but it remains underdeveloped as a practical concept. Far more attention should be paid to human activities like quarrying and mining, which are controllable but have effects that are irreversible.

Commitment, continuity and irreversibility are Cinderella words and concepts, which merit more analysis and prominence in development discourse and practice.

Agricultural settlement in decline: Twists in the tale

After the 1960s, agricultural settlement schemes became less common and less conspicuous. In Africa, their problems and costs, the less land available and political factors combined to reduce their popularity and prevalence. In Zimbabwe, although earlier settlements had been quite successful, the greed and intransigence of the later political leadership prevented an orderly programme that might have served equity and peace by transferring land from European to African farmers, as had been achieved during the 1960s in Kenya. More generally, the withdrawal of the state from administered development such as settlement schemes has been so widespread and so comprehensive that we find ourselves now, in the 21st century, looking back on the 1960s as another world.

Legacies of earlier irreversibility have, though, lingered on, with twists in their tails and tales. The Perkerra Irrigation Scheme has survived. For a long time it was probably still a costly recurrent liability.[11] Reportedly its performance improved somewhat in the 1990s with diversification of crops, and contracts from the Kenya Seed Company for growing hybrid maize seed. A research station was established at Perkerra, jointly under Horticulture Research International and the Kenya Agricultural Research Institute. The irrigated area remained low. Papaya and maize were grown on 350 hectares out of the 2350 hectares designated for irrigation. Perkerra was reported to perform relatively well compared with other irrigation schemes such as Hola, West Kano and Bunyala, which were 'virtually dead' (Akumu, 2002). But the vulnerability and financial dependence of the scheme continued.[12] In December 2002, floods in the Perkerra River destroyed the weir and 259 houses. 'The embankment of the water reservoir which used to flow through the canal to the scheme, and which was built way back in 1954, collapsed under pressure from the waters' (Njeru, 2003). So the history of vulnerability to flash river flows, which in 1919 broke the sill of rock on which the Njemps built their brushwood weir for irrigation, was repeated in 2002. For reconstruction the NIB (National Irrigation Board) was to put in US$20,000[13] and the United Nations Development Fund Kenya, US$100,000.[14] It remains to reflect on the relative ease and low cost of closure in 1959 and for a few following years when there was the option of resettlement in the (as they were) 'White Highlands', and then on the continuing costs of rehabilitating and maintaining the scheme. For each generation of government officers, and for local politicians, the easier course was always to keep it going. Moreover, commitment can hardly have been diminished by the scheme's location in the constituency of Daniel arap Moi, the long-time powerful President of Kenya. The opportunity cost of the funds devoted annually to maintaining the project must have been high, indeed.

The history of the rice-growing Mwea Irrigation Settlement is a contrast. From its inception, it was economically more viable. But, increasingly, during the 1990s farmers' incomes were hit by dues deducted by the management, heavy charges for milling and marketing, and competition from cheap rice imports with liberalization. The centralized administration, seen in earlier days as a strength of the Mwea scheme (Giglioli, 1973; Veen, 1973), gave scope for much resented corruption. Cross-subsidization also took place from Mwea to Perkerra and other schemes. In 1998, farmers rebelled and took over the management, milling and marketing. The next year two young men were shot dead in a confrontation with police (Kenya Human Rights Commission, 2000). In 2003, negotiations were in progress to establish a new relationship between the Mwea settlers and the NIB. Interestingly, the very continuity of the draconian rules and centralized organization of the scheme can be seen as a factor leading to the Mwea rebellion, and its end, for a time, as an administered scheme. The lack of democracy, accountability and transparency, earlier thought to be a strength, had become a liability.

Worldwide, administered agricultural settlement schemes became rare during the 1980s and 1990s. There were fewer resources, less land and the state was in retreat. In India, large- and medium-scale irrigation did not settle farmers, but supplied water to farmers on the land that they already farmed. In Israel, the idealistic and communal organization of the *kibbutzim* eventually came to an end. Elsewhere, the state disengaged where it could from responsibilities to settlers.

Some exceptions to these trends do, though, stand out, ranging from the tightly administered to the near chaotic. For example, on Palestinian land, the closely protected, notoriously illegal Israeli settlements were precisely intended to be irreversible forms of appropriation and colonization, excluding Palestinians from their land. In Sri Lanka, in a humane but closely administered tradition, the Mahaweli Development Authority continued to settle families on newly irrigated land and to provide a high level of special services. In southern Africa, there were limited programmes of buying out large European farmers and settling African smallholders. In Ethiopia, despite the bad record of earlier population transfer and resettlement, the early 2000s saw renewed attempts to resettle people from the highlands to the lowlands. At the chaotic extreme, in Zimbabwe, self-settlement of self-designated freedom fighters took place on commercial farms from 2001 onwards, carried out by force and with disastrous economic consequences.[15] In their different extreme ways, the Israeli and Zimbabwean governments pursued or permitted settlement with gross disrespect for human rights and legality.

As for refugees, in 2003 there were, in the world, some 20 million persons identified by the UNHCR (United Nations High Commissioner for Refugees) as 'people of concern' (UNHCR, 2003). Of these, 12 million were refugees. The remainder included internally displaced persons, stateless persons, asylum seekers and returnees. Refugees were concentrated especially in Africa, Thailand, Iran and Pakistan. Earlier, during the 1970s and 1980s, hundreds of thousands of refugees had been established on agricultural settlements, notably in Tanzania at Mpanda and Ulyankulu. But during the early 21st century, almost all refugees were either dispersed among host populations or held and supported in camps. New agricultural small farming settlement projects for refugees and displaced people followed the global trend and had become rare.

'Oustees', rights and ease of exit

The retreat from agricultural settlement during the 1970s and 1980s was paralleled by neglect by governments of responsibilities for people displaced by dams, roads and other infrastructure projects. In 1994 and subsequently, those displaced were estimated to number worldwide about 10 million a year (World Bank, 1994; Mehta, 2002). With dams, the word 'oustee' came to be used. Earlier, during the 1960s, Nuba and others who lost homes and livelihoods to Lake Nasser, created by the Aswan Dam in Sudan, were given the option of resettlement on the new irrigation project of Khasm-el-Girba; and some 80,000-odd people displaced by the Volta Dam in Ghana were offered resettlement in new communities, which a majority of them took up (Chambers, 1970). But no such responsibilities were similarly discharged in India on any scale, despite the building of many dams and the displacement of hundreds of thousands of marginal and politically impotent poor people. Over four decades in India, 20 million people were displaced by development programmes and forced into involuntary resettlement. Seventy-five per cent of them were without 'rehabilitation', and the vast majority were impoverished by the process (Cernea, 1997). Michael Cernea and his colleagues at the World Bank, and Thayer Scudder and others outside it, showed how damaging displacement was to lives and livelihoods, how widely ignored were the rights and interests of those displaced and how much more numerous they often were than was acknowledged in project documents. As a vigorous and committed group, they were instrumental in drawing up and gaining agreement for the World Bank's policy on involuntary resettlement, issued in 1980. This major step forward was influential both inside and outside lending and donor agencies, though less so with governments. At the same time, internationally networking activists made lenders, donors and, to a lesser degree, governments, more aware of the human costs of dams and other projects that displaced people and more cautious about funding them (Brown and Fox, 2001). Evaluation and research have improved understanding of involuntary resettlement and of what could and should be done (e.g. Cernea 1997, 1999; Picciotto et al, 2001). The World Bank code, international networking and lobbying by civil society, the new human rights agenda, and predictable protests and adverse publicity have increasingly combined to discourage lenders and donors from supporting big projects that displace many people.

The Sardar Sarovar Dam in India, and the Narmada River project of which it was a part, is a case in point. It developed into a high-profile saga with dramatic civil disobedience. The Indian Central and State Governments failed to meet World Bank requirements for compensation and resettlement of the people who were to be displaced. When a distinguished international panel laid bare misinformation and abuse (Morse and Berger, 1992), the World Bank withdrew its support. The Indian Government pressed ahead on its own, facing a long and high-profile campaign of protest led by Medha Patkar and supported by the novelist and activist Arundhati Roy (Roy, 2002).

Other withdrawals of international aid followed for other dams. The UK government backed off from supporting the Pergau Dam in Malaysia when the World Development Movement brought a case against it and a UK court ruled that it was illegal. In 2001, in the face of strong criticism, it also withdrew support from the Ilisu Dam in Turkey, which would have displaced a large Kurdish population and inundated historical sites. Meanwhile, the World Commission on Dams (WCD, 2000; Imhof et al, 2002) set new standards for inclusiveness and consultation, having among its members both Medha Patkar, who as an activist had been on hunger strikes in protest against the Narmada project, and Goran Lindahl, the chief executive of one of the world's largest engineering firms (Dubash et al, 2001, p1). The WCD's remarkable consensus report presents a new policy framework that gives prominence to the rights of people adversely affected by dams (WCD, 2000, p240ff).

In this new climate, international funders, though less so governments (as India's Narmada and China's Three Gorges projects illustrate) have become more circumspect in keeping open options for exit from such projects. With the earlier settlement schemes in Africa, irreversibility of commitment was linked to political and moral responsibility to those who had been settled. After a phase of neglect, such obligations are now again more extensively recognized and accepted. Commitments have become more public and open to scrutiny, more frequently debated and less firm. High-profile opposition has made it easier for funders to withdraw support. The irreversibility found in earlier projects is now less common because of greater awareness of the consequences of displacement and the opposition that new projects provoke.

Commitment, continuity and creativity

Changes in commitment can be understood in the context of the well-recognized changes in development policies and practices of both national governments and aid agencies.

To summarize these in broad brush terms, during the 1950s and 1960s, infrastructure projects were prominent – for example, industrial plants, harbours, roads, railways, telecommunications, airports and irrigation projects. The 1970s became a heyday for area-based initiatives, including Integrated Rural Development Projects promoted and supported by the World Bank (World Bank, 1988). These did not have settlers, only small farmers or pastoralists already on the land; so when many failed, as they did especially in Africa, they were easier to abandon. Unlike Perkerra, they passed into history on the ground, leaving a legacy of disillusion, debts and staff housing. In aid policies during the 1980s and 1990s, structural adjustment programmes became prominent, required by lenders for the repayment of debts. And the 1990s were marked by shifts towards sector programmes and direct budget support, debt relief, good governance, participation and human rights policies proclaimed as pro-poor. As the new century came in, lenders and donors were abandoning field projects and focusing on policy.

Some big projects, though, if well surveyed, fairly administered and then irreversibly implemented, are needed and justified. I was probably wrong, on an International Labour Organization mission to Sri Lanka in 1978, to muster arguments against the Accelerated Mahaweli Development Project to increase hydropower and irrigation and to brand it Sri Lanka's *Concorde*.[16] And who now would wish to argue that it would have been better not to have built the Volta Dam or the Aswan Dam? Some big projects are right. Some are not. And much depends upon how well and fairly they are undertaken.

All of this may be quite well accepted. Perhaps less explored is the changing significance of dimensions of commitment and continuity and their implications for practice. In what follows, much of the focus is on aid agencies, and their priorities, activities and relations with governments; but much also applies to governments themselves. Let us follow the historical sequence and start with projects.

Commitment and continuity with projects

For exploring the relevance of irreversibility and commitment, especially with projects, insights come from Albert Hirschman's classic *Development Projects Observed* (Hirschman, 1967). From a study of 11 World Bank-supported projects, all of which had serious problems, Hirschman put forward his hypothesis of the 'Hiding Hand'. This was the principle that those proposing and planning projects habitually underestimate the difficulties that will be encountered, but that this may be just as well, since they also habitually underestimate the creativity that can be mustered to overcome them. With hindsight, the Perkerra experience suggests that Hirschman may himself have made an underestimate – of the costs of 'creativity', for these can include recurrent costs of staff, subsidies and protection, additional infrastructure and the pre-emption of scarce administrative capacity. Still, in Hirschman's view, too little commitment and too easy withdrawal could mean premature abandonment before there was time to learn and improve. This, he argued, was a weakness of agricultural projects, which were easier to abandon than, say, electric power or railways. Irreversibility, in his view, could be an asset because of the creativity it stimulated and the learning to which it gave rise.

Hirschman's thesis about commitment, continuity, learning and creativity is borne out by the RIPS (Rural Integrated Project Support) Programme in Lindi and Mtwara Regions in Tanzania (Freling, 1998; Groves, 2004). Finland supported a programme there for some 20 years, much of it installing water supplies. By all accounts, these were a substantial failure. Accepting failure and abandoning the project would have been easy to justify. But the Tanzanian Government and the Finns did not give up. They hung in and tried again. There was then a continuity of involvement and commitment of key individuals on both the Finnish and the Tanzanian sides, which fostered a good spirit of long-term trust, understanding and partnership.[17] In 1993, an Indian trainer, Kamal Kar, introduced participatory rural appraisal (PRA) through a series of workshops (Johansson, 2000). Participatory approaches gained strong support from the two regional commissioners, Colonel Nsa Kaisi and Colonel Anatoli Tarimo (and, subsequently, his successor A. Y. Mgumia). Implications for institutionalization and bureaucratic change were recognized (Kar et al, 1998; Swantz, 1998). The programme was transformed. Innovations multiplied (Freling, 1998). To take but one example, participatory media were developed (de Waal, 2000) through a village radio network and through participatory video. These enabled people to make claims and supported mediation between competing or conflicting stakeholders. Participatory video was used in reforming a fish market, forcing officials to use the correct procedures and leading to the person who was 'eating' the tax collected being transferred elsewhere (Nyamachumbe, 2000). It also played a key part in the turbulent process of ending the dynamiting of coral to catch fish (Swantz et al, 2001). Another innovation was to introduce PRA with participatory planning and action in most of the communities in the two regions. The results of this community-level participation were so successful that, through a sequence of national workshops, it influenced Tanzania-wide policy. Results included a permanent secretaries' two-day retreat on participation (MRALG, 1999) and a later one for regional administrative secretaries. Throughout the 1990s, the donor agency and the Tanzania government were co-learners and co-beneficiaries. Had they given up after the earlier 20 years of failure, the positive lessons from pioneering participation would never have been learnt and national policies and practices would not have been influenced.

The Sida-supported Mountain Rural Development Programme in Vietnam is another striking illustration. Sida had a long-standing relationship with Vietnam as the only Western donor who hung in with support through the 1960s and 1970s. A sequence of projects, initially a pulp mill, then for forestry and farm forestry, and subsequently rural development, involved long continuities of staff and relationships. Edwin Shanks and Bui Dinh Toai noted in a paper they wrote for a conference in 2000 that their combined experience was 16 years, having worked on the project since 1993 and 1991, respectively. They also observed that 'due to the relative stability of staffing structures in Viet Nam, many of our colleagues still working on the programme at province and district levels were also involved from the very beginning' (Shanks and Toai, 2000, p23). It is difficult to imagine that the slow, patient and successful introduction and co-evolution of participatory approaches to government agencies in that project could possibly have been achieved without this continuity and sustained commitment.

With aid agencies shifting to sector support and policy influence, development projects were being abandoned during the early 2000s. In Uganda, between one financial year and the next, DFID's (the UK Department for International Development's) ratio of project-to-programme funds shifted with astonishing abruptness from 5:2 to 2:5, without a significant change in total.[18] Ironically, this was at a time when, in my view, lenders, donors and governments were getting better at learning from projects. But as and when these were terminated, governments and aid agencies lost the precious opportunities they had had for innovation and co-learning. With one project in Tanzania, local-level staff had devoted years to project preparation and negotiation only to find that they had been led up the garden path and there would be no project (Groves, 2004). With another in Brazil, after relationships with NGOs (non-governmental organizations) and communities had been built up over three years, people's time and energy had been invested, and enthusiasm and expectations had been raised, a decision was taken in DFID to withdraw, leading to much anger, anguish and disillusionment. The hidden costs of such abandonment can be incalculable. Local people who have engaged in participatory planning and have been led to expect support are left in the lurch and reconfirmed in their resentment and cynicism about government. Field staff are seen to have misled their clients; they are made to look foolish, if not duplicitous, and are furious, embittered and demotivated. Decent and perceptive aid agency staff, too, are demoralized, embarrassed and ashamed, but do not have to face the people on the ground. Centrally isolated office-bound policy makers in northern capital cities may be blithely or wilfully[19] unaware of the distant damage they have done. All too often, abandoning projects was unethical and anti-poor.

With experience from western India comes David Mosse's (2003, 2005) fascinating, perceptive and subtle analysis of the IBRFP (Indo-British Rain-fed Farming Project) with which he was closely involved until 1998, and which he revisited and reviewed three years later in 2001. Despite his early criticisms, and despite managerially exacting contradictions in the project, he shows that much had been achieved, not least through participatory seed breeding and selection. This was a core project innovation that challenged the prevailing regulatory frameworks and bureaucratic practice of Indian agricultural research (Witcombe et al, 1996), with huge implications for policy and practice. The project had also 'brought a version of "development" more meaningful than any previous to Bhil tribal communities excluded from even the most basic state services' (ibid, p24). However, by 2001 it had fallen from favour in DFID and was threatened with closure, not because it was failing but because projects had become unfashionable. As Mosse (2003) puts it:

> Project practice seemed to me unchanged – meaningful engagements between staff and villagers still produced important local benefits even under conditions of severe drought. But a fundamental change *had* occurred, not in the project but in donor policy … DFID's India programme had become reorganized around the funding of state-wide government programmes, sectoral reform and donor–government partnerships. Unable

> to articulate this policy, the IBRFP project began to lose its support and, consequently, its reality. It bore new policy labels of exclusion: 'enclave project', 'niche project', 'replicable model', 'parallel [to the state] structure', 'sectoral, downstream, micro-managed project'. IBRFP had suddenly become the flared trousers[20] of the DFID wardrobe.

In abandoning projects, lenders and donors have succumbed to a tragic pathology. Notwithstanding the common view of colonialism, I found, in the late colonial settlement projects that I studied in Africa, a strong commitment of local-level administrators to 'their' projects and to the settlers. Administrators on the ground were face to face with the realities. To varying degrees, subsequent political representation also provided commitment and support to local projects. It is only now, with lenders, donors and policy makers interacting and influencing one another more and more, insulated in their capital city cocoons, that projects can more easily be abandoned. RIPS in Tanzania, the project in Brazil, and IBRFP in India all provoke sad reflection on the costs of abandoning projects: staff demoralized, people disillusioned, government discredited, 'money down the drain', benefits to the poor forgone, and opportunities lost for ground-truthing, learning, innovation and capacity-building. In our brave new 21st century of aid, for many poor people, projects have not proved irreversible enough.

Commitment and continuity with policy

This view gains new relevance with the dominant development aid policies of the new century. There are signs of a new consistency in two domains: in rhetoric, extolling partnership, country ownership and policies that are pro-poor; and in targets, with the international and now MDGs (Millennium Development Goals) set for achievement by 2015. Sector programmes may, perhaps, not demand as much long-term commitment as projects. But whether for projects or for sector support, inconstancy is a feature of much aid. In this, agencies differ. United States Agency for International Development (USAID), for example, stands out for its short-term swings of policy and vocabulary, and its relative unreliability.[21] Overall, the shift from projects to sector programmes and policy influence may have meant a move for aid agencies from the grounded, bounded and stable to the more nebulous, permeable and inconstant.

With projects, failures were harder to hide. There were reasons to hang in there and try to make them work. With sector support, failures by lenders, donors and governments may, perhaps, tend to be less embarrassingly conspicuous and responsibility less attributable. More actors are involved. The scale is wider. The impacts are further away. So responsibility and accountability are more diffuse. Both political risk and institutional commitment have diminished. In consequence, it may be easier to exit and to deny responsibility. The new dangers implied may not be well recognized by lenders, donors and recipients. The dangers include, as Albert Hirschman might note were he to revisit the aid scene, that less long-term commitment and less continuity mean less creativity and less learning.

Personal continuity, motivation and effectiveness

With the shift of emphasis in aid from projects to sector programmes and policy influence, and with the language of partnership and ownership, so relationships and continuity have become ever more important (Eyben, 2004; Groves and Hinton, 2004). Good relationships are fostered by continuity of aid agency staff in country and in post. Continuity also provides incentives and opportunities for vital learning. How can a foreigner be engaged in sensible policy dialogue without knowing and understanding a country?

A crucial aspect of continuity is people staying in the same post, place or sector, gaining experience and developing good working relationships. Quite exceptionally for an Indian Administrative Service officer, Syed Hashim Ali was left in charge of irrigation command area development in Andhra Pradesh for seven years, from 1974 to 1981. Through this continuity and his personal commitment, much learning took place and he was able to make and oversee major shifts and improvements in policy and practice. Continuity in linking field experience with policy can also be important. E. G. Giglioli's experience as manager of the Mwea Irrigation Settlement was crucial to the insights and authority that he later brought to the establishment and management of the NIB in Kenya (Chambers and Moris, 1973).

Partnerships in the Philippines and in Uganda show how continuity and long-standing relationships can be the foundation for major changes. Over some ten years in the Philippines, Benjamin Bagadion of the National Irrigation Administration and Frances Korten of the Ford Foundation worked together with a stable network of colleagues. During this time they were instrumental in gradually transforming much irrigation policy and practice (Bagadion and Korten, 1989). In Uganda, the UPPAP (Uganda Participatory Poverty Assessment Process) was promoted and supported by an alliance of champions in both donor and recipient organizations working closely together over a number of years (Yates and Okello, 2002, pp90, 93; Kakande, 2004). It continues as an innovative programme that has given poor people's priorities policy clout and has also influenced PPAs (participatory poverty assessments) in other countries. In my judgement, neither the Philippine irrigation reforms nor UPPAP could have occurred without the relationships, trust and shared purpose, which could evolve because the main actors remained for some years in their posts and organizations. Without that continuity, the loss would have been not just national, to the Philippines or to Uganda: irrigation management in the Philippines has probably been more influential worldwide than in any other country, and UPPAP experience has influenced many other PPAs. The loss would have been international, to many countries and to our understanding of how to do better in development.

Expected and actual continuity in post has profound effects on motivation, behaviour and learning, whether in government, INGOs (international non-governmental organizations) or aid organizations. Over time relationships can go beyond mutual respect and collegiality and flower into friendship.[22] Three conditions that help are long journeys together by car or train, mild hardships in the field and a shared vision. Continuity in post and relationships rise in some places and decline in others. In INGOs, in some countries, there is an impression that staff are switching organizations with greater frequency, treating them as stepping stones more than as places in which to stay and work for a matter of years. But those who do hang in gain types of experience denied to those who hop about. World Neighbours, one of the most innovative INGOs, has staff members with over 20 years' service. In recruiting it looks for people whose careers have shown 'stick-to-itiveness' – that is, who have stuck to the same job or organization for a substantial time (Jethro Pettit, pers. comm.).

The behaviour of those who expect short spells is predictable. If foreigners, they lack incentives to learn a local language or to take pains to understand local people and conditions, or to take a long view. If energetic and committed, they are liable to be tempted to go for actions with quick effects, neglecting those that need longer-term negotiation and support. For aid agency staff, 'It is difficult to learn and to assume a long-term vision in a local donor community. Each individual is operating in a short time frame related to average residence of three years in any country and she wants to see herself as having "made a difference"' (Eyben, 2003, p28). In their haste, staff make mistakes from avoidable ignorance. Not having to stay long enough to deal with intractable problems, they do not have to muster Albert Hirschman's creativity in overcoming them. Moving on soon, they are not there when the chicken comes home to roost. There is little incentive to develop more than superficial relationships, and as Rosalind Eyben has argued and shown, relationships matter for supporting change in favour of poor people (Eyben, 2004).

Opportunities to learn and change are missed. These are among the costs of staff moves in the restructurings endemic, if not epidemic, in some aid agencies. Uncertainty and transfers impede other changes. In ActionAid in the UK, the introduction of the new radical ALPS (Accountability, Learning and Planning System) became increasingly difficult when 'staff were coming and going at all levels' as part of a massive restructuring process (David and Mancini, 2004, pp17–18). Individual and organizational learning are hampered. Lack of continuity means that by the time lessons can be learnt from what works and what does not, and how mistakes can be mitigated, staff have moved on. After reviewing the history of a donor-supported development programme in Kenya, Samuel Musyoki (2003, p166) concluded: 'The staff turnover in bilateral programmes is very high and there is a tendency of the new management to erase history and create a new knowledge base.' Just as the benefits of continuity are habitually underestimated, so too are the costs of premature transfers. A successful incumbent in almost any responsible post, whether in a government, national NGO or aid agency, tends to achieve more in a third year than in the first two together, and again more in a fourth year than a third, by which time much has been learnt, and relationships and understandings have had time to mature. Diminishing returns set in, if at all, after five or six years or more.

The importance of continuity is also indicated in the reactions of developing country nationals, whether in governments or NGOs, to foreign staff, and whether this is at local or central levels. They resent the short time that those in aid agencies spend in one place. No sooner have they got to know and developed a working relationship with one person than they leave, another takes over and they have to start all over again. Relationships are fractured and understandings are undermined. In the words (October 2003) of a developing country national about USAID 'When we negotiated there was a very good person. Then the boss changed and was very bureaucratic and she left.' Such discontinuities occur with nationals working in INGOs as well as with foreigners. ActionAid's community development workers in The Gambia 'have, on average, been moved every one or two years, with the attendant need to familiarize themselves with a new area, to build trust and sometimes even to learn a new language before they could start to perform to a reasonable standard' (Howes, 2002, p114). When some ActionAid staff in India were concerned that their local NGO partners would resent their relatively high salaries, they were surprised that there was no objection as long as they stayed in the same place for a decent length of time. Then they could get to know one another and develop mutual understanding. Salaries were unimportant compared with continuity and longer-term relationships (Amar Jyoti, pers. comm.).

In sum, the costs of lack of staff continuity are unseen, unaccounted for, incalculable and often unnecessary. At the same time, continuity is not a simple thing, always to be maximized. From the point of view of a foreign agency, a danger is perceived of out-posted staff 'going native', becoming personally, professionally and emotionally too close and too attached to a country and people. When staff fail it can be right to transfer them. When they move they learn new things. But with the focus of aid on policy, it matters more than ever for aid agency staff to understand local conditions.[23] The costs of lack of continuity, always high, have risen further. Only three years in a post looks too low. The proximate costs of early transfers are relationships broken, trust undermined, demotivation and learning forgone. The wider effects are bad for poor people through errors of judgement and what is then done and not done.

Responsible commitment and continuity can, then, be seen to matter now more than ever. They are a moral imperative where poor people have been led to invest their time and energy in expectation of support. They are a practical condition for constructive relationships, trust and learning. Understanding and optimizing commitment, continuity and their synergies should be high on the agenda for development in the 21st century.

Irreversibility

When a word lodges in the mind, it surfaces in different contexts. So it has been for me with 'irreversibility' since writing my thesis.[24] What began with seeing how commitment to settlement schemes could be irreversible, as with Perkerra, led to thinking of and seeing irreversibility in other domains, including economic decision making and environmental change.

To sharpen the issues, consider extreme and tragic forms of irreversibility. Perhaps the best known is the extinction of species. A world without the tiger, white rhinoceros or panda would be profoundly diminished. Nor is this a question of only such iconic species, but of a great range that are endangered. The irreversibility and uncertain risks of GM (genetically modified) crops are another case. Less recognized is the destruction of rocks. A stark tragedy is the destruction through quarrying of rocks near Delhi and in and near Hyderabad.[25] These were formed billions of years ago and have weathered over geological time. Apart from intrinsic worth, they have (or had before being destroyed) cultural, aesthetic, ecological, recreational and spiritual value to us humans, giving experiences of place and beauty, sustaining a diversity of life, and providing for the recreation and fulfilment of rock-climbing. Their destruction is utterly irrevocable. Trees that are cut can be replanted. Even soil that erodes can be replaced. But with rocks, restoration is not an option. Once blasted and removed, they are gone. Forever. With a dreadful finality.

Reflecting on these biological and physical examples, if we are to assure options and resources for future generations, irreversibility simply has to be a key concept embedded in our thinking and informing our decisions and actions and non-actions. It is then striking that it is not significant in mainstream economic thinking. Much attention is paid to *risk* – 'the probability or probability distribution of an event or the product of the magnitude of an event and the probability of its occurrence' (Alcamo et al, 2003, p214) and *uncertainty*, the condition of not being known or predictable, where the probability distribution is not known (Devereux, 2001, p508), and each has a considerable literature. But *irreversibility* is less well developed and less frequently mentioned as a concept. Two standard economics textbooks – *Economics* (Begg et al, 2003) and *Economic Development* (Todaro and Smith, 2003) – include risk in their glossaries; but neither mentions irreversibility.

Not only is irreversibility little considered, but conventional economic practice systematically undervalues it. First, discounting gives low or negligible present values to distant future benefits or costs (Chambers and Conway, 1992, pp18–19). Present value has, however, often been taken as a basis for decisions. To correct this, Zhao and Zilberman (1999) have proposed a new concept of irreversibility cost, and point out that discounting may encourage a pattern of developing now and restoring later. This applies, for example, with the high costs of decommissioning nuclear power stations, which in present value terms were very low at the time of deciding to build them. Irreversibility traps a project or society into having to pay such costs.

Second, substitutability is invoked, with the idea that technological development will find substitutes for resources or services that are depleted, damaged or destroyed. In this view, depletion and degradation of ecological capital are not irreversible in the sense that they can largely be overcome by the accumulation of knowledge and of manufactured and human capital.[26] However, even if technological substitutes exist or are found, their cost is typically high, limiting access to those who are more affluent and putting them beyond the reach of communities and people who are less well off.

Third, non-renewable natural capital resources, like rocks, minerals, oil or gas, are not normally given intrinsic value in economic assessments. When they are irreversibly exploited they appear in themselves costless. To be sure, there are the costs of land, licences and royalties, and of extraction, processing and bringing into use; and sometimes costs are attributed to loss of amenity and physical and ecological damage. But non-renewable natural resources are not given an inherent capital value. So they come out on the wrong side of the ledger as benefits when, unless recycled, they are more strictly costs in the form of irreversible losses.

Fourth, the cultural, aesthetic, ecological, recreational and spiritual values threatened or diminished by irreversible 'development' cannot be measured in money; yet they are deep elements in the quality of human life and experience. Attempts to measure some of them in cash equivalents appear crude. What is the dollar value of being able to watch a bird or climb a rock, now and for future generations? Some may justify giving these a cash value as a short-term expedient in order to talk to hard-core economists in their own terms. In my view, responsible imagination and reflection on stewardship of the heritage of countless future generations will always be better and should carry more weight.

The effects of these biases and neglect are pervasive. Take even the report of the World Commission on Dams (WCD, 2000). Though a remarkable achievement and *tour de force*, it does not give irreversibility as much prominence as the concept would seem to merit. For irreversibility applies both to structures and their impacts and to decision processes. Despite siltation, earthquakes and other hazards, dam structures and their immediate impacts are large and irreversible. As for decision making, the central values that run through the report are equity, efficiency, participatory decision making, sustainability and accountability. Irreversibility is mainly addressed indirectly, by presenting five key decision points in planning and project development. Although the last of its seven criticisms of cost–benefit analysis is ignoring 'the effect of uncertainty and irreversibility of investment', the report does not make irreversibility a central issue (WCD, 2000, ppxxiii, 181, 263).

Over the past decade, and offsetting such biases and neglect, some economists have given more attention to irreversibility and related concepts. Faucheux and Froger (1995), for example, examine decision making in the conditions of uncertainty, irreversibility and complexity, which they say characterize most environmental problems. Zhao and Zilberman (1999) distinguish between technical irreversibility, when technologies to mitigate negative impacts do not exist, and economic irreversibility, when 'it is not optimal to restore the development even though technologies exist to do so' (ibid, p560). This is because of the level of what they call irreversibility costs or restoration costs. Faucheux and Hue (2001) in their article 'From irreversibility to participation: Towards a participatory foresight for the governance of collective environmental risks' move the discussion into the social realm, stressing the need for vigilance and describing experiments with forms of participatory 'social foresights' – which articulate 'demand' as signalled in the views of citizens. These include public inquiries, citizens' panels, citizens' juries, consensus meetings and mediation.

Issues around irreversibility became clearer in 2002 in discussions about concepts for the MA (Millennium Ecosystem Assessment). The MA is an ambitious project to understand better the relationships between ecosystems, ecosystem services and human well-being. Members of the multidisciplinary group of 51 authors met four times to evolve the conceptual framework[27] published as *Ecosystems and Human Well-being: A framework for assessment* (Alcamo et al, 2003). This defines concepts relevant to this discussion (ibid, pp208–216). *Irreversibility* is 'the quality of being impossible or difficult to restore, or return to, a former condition'. Reversibility is related to *resilience* – 'the capacity of a system to tolerate impacts of drivers without irreversible change in its outputs or structure'. *Thresholds* are 'a point or level at which new properties emerge in an ecological, economic or other system, invalidating predictions based on mathematical relationships that apply at lower levels… Thresholds at which irreversible changes occur are especially of concern to decision makers.'

In the MA's conceptual framework, values are seen to bear heavily on decision making where thresholds and irreversibility are or may be involved. In the process of evolving the framework, values were much debated, both as *intrinsic* – the value of someone or something in and for itself, irrespective of its utility for someone else, and as *ecosystem services* to human well-being, classified as provisioning, regulation and cultural. Cultural values were recognized as spiritual and religious, recreation and ecotourism, aesthetic, inspirational, education, sense of place and cultural heritage (Alcamo et al, 2003, p5).

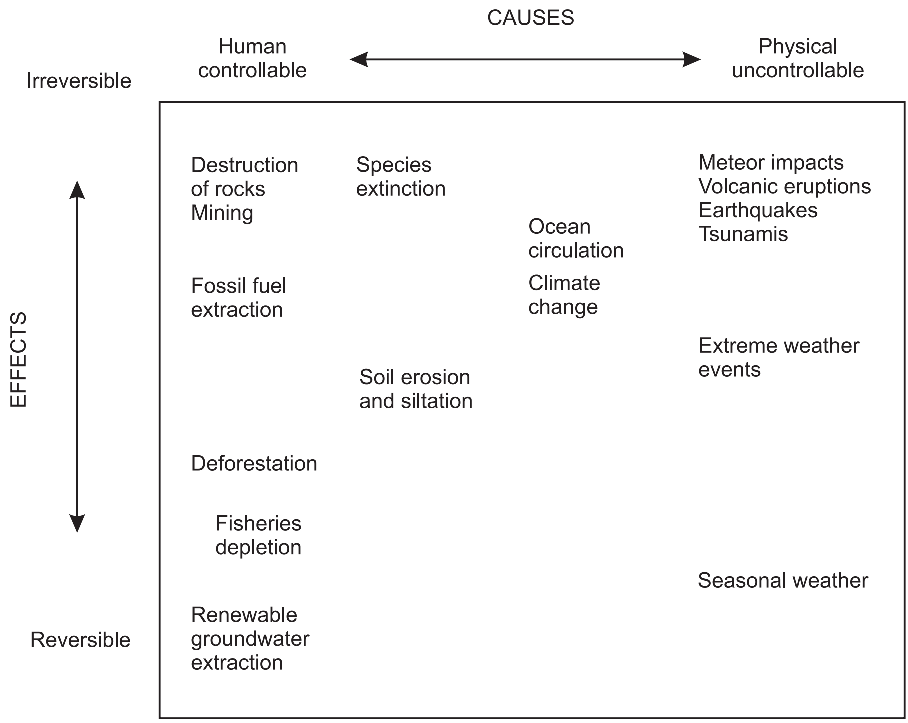
A recurrent theme was keeping options open for future generations. For this, *option value* was defined as:

> … the value of preserving the option to use services in the future either by oneself (option value) or by others or heirs (bequest value). Quasi-option value represents the value of avoiding irreversible decisions until new information reveals whether certain ecosystem services have values society is not currently aware of (Alcamo et al, p213)

The precautionary principle, embodied as Article 15 of the *Rio Declaration* (United Nations, 1992, p3; see also Harremoës et al, 2002) applies here. This is the management concept stating that in cases:

> … where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

Despite all of this, and the way it underlies much of the precautionary principle, irreversibility remains an underdeveloped concept.[28] Further steps are needed to distinguish types, degrees and sequences of reversibility and irreversibility. One approach is to classify changes as clusters according to two dimensions: causes,



Source: Developed in discussions with Christopher Chambers and Jenny Chambers

Figure 6.1 *Clusters of environmental change by types of cause and irreversibility*

polarized between primarily human and totally physical; and adverse effects, polarized between reversible and irreversible (as in Figure 6.1). In the north-east of the figure are irreversible large-scale events beyond our control, most of the effects of which are irreversible – earthquakes, meteor impacts and volcanic eruptions. In the east are tsunamis and extreme weather events such as tornadoes, hurricanes, floods and droughts that are uncontrollable, but where there is more scope for mitigating adverse effects. In the south-east is seasonal weather, uncontrollable but often with reversible adverse effects. In the south-west is renewable groundwater extraction, and above it deforestation and fisheries depletion, which are less reversible, at least in the shorter term.[29] While these are all vitally important, and so often demand urgent and sustained intervention, it is the remaining areas that merit the closest and most intense attention: the north-west with mining, oil and gas extraction, quarrying and species extinction – controllable but irreversible; and the north and centre with climate and ocean circulation change, and soil erosion and siltation. These are areas where human agency is a major cause and adverse effects are irreversible in the medium and long term or forever. It is in these areas that long-term future options are closed off through human action, and that the precautionary principle applies, and should be made to apply, with most force.

To take the rocks example, the short-term gain from blasting the rocks near Delhi or Hyderabad for building contributes to current livelihoods and GDP (gross domestic product), but is at the cost of cultural, aesthetic, recreational and spiritual experiences of future generations *forever*. And these generations, let us hope, will be billions of people over thousands, if not millions, of years. To destroy such rocks manifests an extreme of blinkered and myopic philistinism.

As articulated, the precautionary principle does not fit, and is too weak for this context. There is no lack of certainty. And the term *cost-effective* leads us astray for two reasons: first, we are concerned with incommensurable values not susceptible to economic calculus; and second, discounting overvalues the clear short-term economic gains and ignores millennia of future benefits. To offset this weakness, much depends upon social and ecological responsibility, access to information, the exercise of imagination, and commitment to the democratic representation of future generations who, we must hope, will dramatically outnumber us, giving their interests a very high weighting.

Any broader formulation of the precautionary principle risks a comprehensiveness that could be used to support a conservationism that would discriminate against today's poor people. Nothing that follows should undermine the moral and practical case for participatory conservation (see, for example, Ghimire and Pimbert, 1997). The concern has to be a balance of the social and environmental, of values and actions, and of the present and future. Each of us might wish to think through and elaborate our own version of a revised precautionary principle. Here is mine:

> In the interests of poor people, future generations and the planet, where there are threats or certainty of serious or irreversible environmental damage or loss, neither lack of full scientific knowledge nor short-term economic gain shall be used as a reason for postponing preventive action that is socially and ecologically responsible. The more irreversible the damage or loss, the greater the urgency and the higher the cost justified to prevent it.

This formulation is a provocation for reflection, not final words, and surely for debate. Not least, there are questions of what is damage and what is social and ecological responsibility. There will also always be trade-offs. But this at least can be concluded: irreversibility is a practical concept; it needs more analysis and elaboration; and it should have more weight in decisions and actions. In understanding and applying it, the key is, perhaps, to struggle, and to struggle in every context and in every generation, and to act in ways which are responsible, socially and ecologically, both for the present and the future.

Cinderella concepts and criteria

In the contexts reviewed above – of settlement schemes and other bounded projects, of staff motivation and performance, and of the environment – ideas of *commitment*, *continuity* and *irreversibility* manifest themselves in different forms, with different implications. What stands out in common is that they have been relatively neglected as concepts and as criteria for weighing choices, for deciding what to do and for evaluation. As the restless search for novelty in development impels us to learn and use new words, concepts and criteria, old ones are buried and forgotten. This is the more so with these three since at no time have they enjoyed much popularity in development. They have been marginalized even more by the new prominence of the words which refer to power and relationships: empowerment, ownership, partnership, participation, accountability and transparency. Commitment, continuity and irreversibility have become more than ever Cinderellas, unrecognized and overlooked.[30] Yet, as I have argued, they are fundamental to good development practice.

Most surprising is the neglect of continuity of staff in post. It is easy to measure, which makes it odd that it is so rarely done. Part of the explanation may be that it is so often determined by personnel or human resource departments that are out of touch with field realities, or by central people in senior posts, or by politicians, or by combinations of these. One transfer can generate a chain of other transfers, multiplying its costs. The bad effects of one transfer can then be immense, though unseen, unmeasured and unrecognized. Too long in a post can also be bad, with loss of freshness and excitement; and there is a positive side to transfers – they can give a new clean start, re-energize and broaden experience. But all too often time in post is too short.

The neglect of commitment is less surprising. It is more abstract and not amenable to measurement. It is to be optimized, not maximized. Its dimensions are diverse: they can be personal – with commitment to, for example, an ideal, a cause or a relationship; or organizational – with commitment to a programme, project, a group of people or a mission; or political – with commitment to a programme or policy. Commitment is also contextual, evolutionary and difficult to forecast.

As for irreversibility, in economics it has been overshadowed by preoccupations with risk, uncertainty and sustainability. It has not been incorporated significantly into economic analysis. It is difficult to quantify and it confronts and contradicts conclusions that come from discounting. Nor is it always bad: as with continuity, more of it can be better or worse, depending upon the case. If factors like these explain why it has been such a marginal concept, the case is strengthened for offsetting them, developing it further as a concept and giving it more prominence.

Questions of commitment, continuity and irreversibility are relevant to much decision making and action. The issues they raise differ by context. It is tempting, then, to dismiss them as too vague and variable to be of much use. But there is a paradox here. For the very diversity of their meanings makes them versatile in their applications. The lesson is not to pass them by, but to define and apply them, context by context. They should be part of any checklist of criteria for review in formulating policies, making decisions and taking action. They deserve to be brought out of the shadows into the light closer to centre stage. Given more weight in development, and applied again and again, they should prevent or reduce damage from errors and, at the same time, ensure that more good things are done.

Notes

1 Mwea was so frequently visited by VIPs, researchers, school parties, women's groups, government officials and others that the manager told me he spent 45 per cent of his time on public relations. This led to the recruitment of a deputy manager for whom this was his major work.

2 The recent history of Mwea has been turbulent. During the late 1990s, farmers increasingly protested against the National Irrigation Board's corrupt management and high service charges. In January 1999, two young men were killed by police in a demonstration. The farmers took over the scheme to run it themselves (Kenya Human Rights Commission, 2000). This evidently failed, and, in January 2003, negotiations between the farmers' cooperative and the National Irrigation Board led to the formation of a committee to oversee the scheme (*Daily Nation*, 27 and 29 January 2003).

3 This section is from Chambers (1969, pp257–262). A few details of evidence have been edited out, together with a paragraph on Perkerra.

4 I struggled with my wish to change 'men' to 'people'; but have left the male-biased word, which was in the original. It situates the piece historically. This was before the gender-awareness revolution. That said, Jon Moris and Jane Hanger, the authors of the much-cited and influential Chapter H, 'Women and the household economy', in the Mwea collection (Chambers and Moris, 1973, pp209–244) deserve credit for showing how markedly settlement conditions made things worse for women, leading, for example, to a high rate of divorce.

5 Nicholas, in *Volta Resettlement Symposium Papers* p86, subsequently edited and republished in Chambers, 1970.

6 Interim report of a United Nations Special Fund survey of the lower Tana Basin in Kenya, as reported in *East African Standard* (Nairobi), 17 November 1965, and *Daily Nation* (Nairobi), 17 November 1965. Despite a long sequence of adverse appraisals, the project (named Bura) was eventually implemented and must rank as one of the economically most disastrous settlement projects ever.

7 The heading in the original text was 'Concluding'.

8 The word now would be appraisals. Evaluations are ex post, appraisal ex ante, but this distinction was not yet a convention in the late 1960s.

9 *Mea culpa.*

10 This section is taken from the final pages of Chapter M 'The Perkerra Irrigation Scheme: A contrasting case', in Chambers and Moris (1973, pp344–364). I would like to thank the past and present officials of the Kenya government who have helped me with the research for this case study. I am especially indebted to E. G. Giglioli, J. G. Stemf, S. G. Sandford and R. E. Wainwright for comments on an earlier version. Responsibility for what is written here is, however, entirely mine and should not be attributed to any other person or to any organization.

11 Attempts to obtain accounts or details of how Perkerra was financed have not been successful. There are reasons to infer that the cross-subsidization through the National Irrigation Board using surpluses from the more viable Mwea Irrigation Settlement continued until 1998, when the Mwea farmers rebelled; but I have been unable to substantiate this with direct, authoritative or numerical information.

12 According to one report, which remains unconfirmed, the Perkerra staff went unpaid for six months when the Mwea settlers rebelled and cross-subsidization of Perkerra from Mwea ended.

13 This equates to 1.5 million Kenyan shillings.

14 *Daily Nation*, 21 March 2003, http://www.nationmedia.com. This may have subsumed the earlier US$20,000 pledged by the National Irrigation Board.

15 This is not to justify the gross inequalities of landholdings in Zimbabwe. The government, however, chose not to take up aided programmes of settlement of the sort that had been so successful in Kenya. There were numerous reports of how farm labourers suffered and lost when land was seized.

16 In October 2003, *Concorde* had its historic last flight. The Mahaweli project is still alive, extensive and, to the best of my knowledge, well.

17 A contributory factor reflecting continuity of relationships may have been that the Tanzanian President was a Finnophile. The only place in Tanzania with a sauna bath was, and to the best of my knowledge remains, Mtwara. Though its construction provoked a divisive ideological debate among Finnish expatriates, it could hardly have been a political liability when it was patronized, as it was, by the president.

18 Statistics for DFID aid to Uganda compiled by Lister and Nyamagusira (2003) from www.DFID.gov.uk/sid for 1999/2001 and 2000/2001, respectively, give project aid dropping from UK£41.467 million to UK£17.686 million, and programme aid rising from UK£17 million to UK£45 million. The possibility must be recognized that part of this dramatic contrast may have been the result of a change in accounting.

19 To be wilfully unaware is to decide not to know or not to take steps to know, when it is apparent that there is something discordant to understand. Most people do this from time to time. I certainly do.

20 Hanging in and patience can bridge gaps until fashions come back in again. My grandmother's long skirts were for long a legacy of the past, but became *avant garde* fashion when hemlines dropped again, and casual observation suggests that, in 2003, for some young women at least, flared trousers have come back. Those aided projects that survive may in due course find themselves part of a wave of the future.

21 USAID's lack of long-term commitment and tendency to lurch from one priority and language to another is a commonplace development experience, has done much hidden damage and deserves a special study. An example is its policies towards family planning. In Jordan, for example, support to a project was withheld after field preparations had begun. 'In such situations, with expectations raised at the local level, organizational credibility is diminished, and time and energy must be spent to regain the trust of partners in the field' (bint Talal, 2003, p190).

22 I owe the word friendship to Norman Uphoff, who frequently stresses it in Gal Oya (Uphoff, 1992), and to Elmer Ferrer at the Community-based Coastal Resources Management Festival, held at Subic Bay in the Philippines in June 2003, who eloquently stressed how friendship had been fostered by people from different backgrounds and organizations staying together for a long time, working with a common cause.

23 Rosalind Eyben (pers. comm.) has pointed out that: 'Interestingly, the FCO [Foreign and Commonwealth Office of the UK government] now has "anchors", so although someone is only posted for three to four years at any time to a particular country, they do go back again later on and possibly for a third time, as well, during their career. Diplomats appreciate the importance of local knowledge much more than do aid staff.'

24 While courting my wife Jenny, I was in Bihar when she had an excellent job offer that would have put us in different continents for two years. Forced to communicate by cable with few words, I pleaded with her to 'minimize irreversibility commitment'. To my great good fortune, though not necessarily hers, it worked.

25 I write this with passion, anguish and guilt. One of the biggest, most selfish errors of my life was to spend many of the Sundays during three and a half years living in New Delhi rock-climbing on endangered rocks at Damdama and Dhauj, instead of devoting my time to saving them and their environments for future generations. The finest rocks are still, but precariously, intact at the time of writing (2004); but at Dhauj outlying rocks have been mindlessly quarried and destroyed for-

ever. In Hyderabad a vigorous Society to Save Rocks has done great work; but to my knowledge there is no equivalent in Delhi, or, indeed, in any other city in the world.

26 For a discussion of substitutability and well-being, see Alcamo et al (2003, pp79–81).

27 I was lucky to be involved both in drafting the chapter on human well-being and in plenary discussions across the whole range of subjects. This was one of the most stimulating and mind-opening experiences of my life.

28 I will be grateful to anyone who can contradict or qualify the assertion that irreversibility remains underdeveloped as a concept.

29 Caution is needed here in distinguishing cases. Some groundwater can be renewed in an almost linear manner. However, restoration to a former condition implies a reversibility that is not characteristic of ecological systems. Depletion, as through overfishing, may take an ecosystem below a threshold of resilience, so that 'recovery' is very slow or follows a pathway to a different species composition and community structure. In Newfoundland fishery, the failure of cod to recover quickly is an illustration of this (David Schoeman, pers. comm.).

30 The Cinderella analogy works as a metaphor for exclusion by those with power and influence. Her ugly sisters did this to Cinderella. Ugly in this sense myself, I was responsible for excluding 'continuity of staff in their posts' from the prescriptions of an IDS (Institute of Development Studies) policy briefing paper on power, procedures and relationships (Chambers et al, 2001), as I recollect murmuring that continuity was 'old hat'.

Well-being and Ill-being: The Good and the Bad Life

D. Narayan, R. Chambers, M. K. Shah and P. Petesch

Well-being is Multidimensional

A better life for me is to be healthy, peaceful and to live in love without hunger. Love is more than anything. Money has no value in the absence of love.

A 26-year-old woman, Dibdibe Wajtu, Ethiopia

The starting question posed by the researchers to the small group discussions with poor women and poor men is, 'How do you define well-being or a good quality of life, and ill-being or a bad quality of life?' From these discussions emerge local people's own terminology and definitions of well-being, deprivation, ill-being, vulnerability and poverty. The terms well-being and ill-being were chosen for their open-ended breadth, so that poor people would feel free to express whatever they felt about a good life and a bad life. 'We are trying to present a new way of seeing well-being', notes a researcher. It is the way poor people see it themselves.

Poor people's ideas of a good quality of life are multidimensional. As explored in Part I of this chapter, they cluster around the following themes: material well-being, physical well-being, social well-being, security, and freedom of choice and action. All of these combine pervasively in states of mind as well as body, in personal psychological experiences of well-being. Much of ill-being was described as the opposite of these. Part II examines these dimensions in turn: material deprivation; physical ill-being; bad social relations; vulnerability, worry and fear, low self-confidence; and powerlessness, helplessness and frustration. Part III describes the psychological dimensions of well-being and ill-being. In describing the conditions of their lives, poor children especially express resentment.

Reprinted from Narayan D, Chambers R, Shah M K and Petesch P. 2000. Wellbeing and illbeing: The good and the bad life. In Narayan D et al (eds) *Voices of the Poor: Crying Out for Change.* Oxford University Press, Oxford, chapter 2, pp21–43. By permission of Oxford University Press, Inc.

Part I. Well-being: The Good Life

How poor people put it

Ideas of well-being are strikingly similar across the range of participants. Despite differences of detail, and contexts that are diverse, complex and nuanced, the commonalities stand out. The same dimensions and aspects of well-being are repeatedly expressed, across continents, countries and cultures, in cities, towns and rural areas alike. And they are expressed by different people – women and men, young and old, children and adults.

For women in Tabe Ere in rural Ghana well-being means security: being protected by God, having children to give you security in old age, having a peaceful mind (*tieru villa*), patience (*kanyir*, meaning not holding a grudge against anyone), and plenty of rain.

To have most, if not all, of the necessary basics of life is *umoyo uwemi* and *umoyo wabwino*, well-being as described by different groups in Malawi. These basics include certain assets, adequate food, decent medical care, constant and regular sources of income, nice clothes, good bedding, a house that does not leak, a toilet, a bathroom, a kitchen, healthy bodies, couples being respectful of each other, being God-fearing, having well-behaved children who are not selfish and having peace of mind.

For those in Khaliajuri in rural Bangladesh having a good quality of life means having employment for the whole year, a good house, four or five cows, a fishing net, good clothes to put on, food to eat to one's heart's content and being able to protect one's house from flood erosion. Middle-aged women say that for a good quality of life there should be a male member of the household earning money, a son for every mother and no husbands pursuing polygamy.

A participant from Renggarasi in rural Indonesia considers a person to be living well who can secure his family's needs with produce from his livestock and who is able to help others who need material and non-material things or advice.

In Nigeria well-being is described by different people as being a responsible person who has a pleasurable life, peace of mind, security and independence, and who is popular with the people, is able to marry easily, is able to educate children, is able to patronize private clinics and schools, and who has money, land, a house and good clothes.

In Bulgaria the major distinctive feature of well-being is stable employment, which means having money as well as security. The National Synthesis Report notes that the family is another important aspect, along with being able to socialize and being in harmony with oneself. The wealthy, seen as those who have and flaunt money and power, do not necessarily have the respect and security that the community considers essential parts of well-being.

In the Kyrgyz Republic, 'informants understand well-being as good life and wealth; however, they do not think that well-being is limited to these tangible components, and believe that well-being is impossible without tolerance, peace, family and children. The informants think that the basis of well-being is good health, peace in the family and in the society; in their opinion, wealth, which is an important component of well-being, can only be gained if these conditions are present.' From the Kyrgyz Republic it is also reported that most of the informants define well-being as 'stability on a household and society level and ability to satisfy one's material and spiritual needs'.

In Barrio Las Pascuas in urban Bolivia, a group of youths say that those who have a good life are 'those who do not lack food', and those 'who are not worried every day about what they are going to do tomorrow to get food for their children. They have secure work, and if the husband does not work, the wife does.' In Nuestra Señora de Guadalupe in another part of urban Bolivia young men say that, besides having adequate food and work, well-being is to be friendly and to have friends, to have the support of family and society, and 'to be patient, and above all happy'.

Materially, enough for a good life is not a lot

> *I would like to live simply. I don't like houses with too much inside. To have a bit more comfort. Nothing big … I would like a simple house … not big, or luxurious … a simple house with a floor.*
>
> A 21-year-old man, Esmeraldas, Ecuador

It is perhaps part of the human condition to aspire not for the moon, but for imaginable improvements. Participants were clear that enough materially for a good life for them was not excessive or unrealistic (see Box 7.1). They hope for moderate, not extravagant, improvements. They do not see substantial wealth as necessary for well-being. Rather, they express the material dimension of life in terms of having enough for a reasonable level of living. And the material is only one dimension among others.

It is not just that poor people's material aspirations are modest. It is also that the worse off they are, the more a small improvement means. A little then means a lot. This may apply especially with women who so frequently have so little. For women in two Malawi rural sites part of a good life is having adequate utensils, especially pails for drawing water and a rack for drying plates. To a discussion of well-being in Bangladesh, a group of older women add, 'Those who could pass time for the prayer of God after taking a full meal and could sleep on a bamboo-made platform live a good quality of life.'

None of this justifies modest ambitions in development, accepting the horizons of poor people where these are limited, or restraining efforts to help them and to help them help themselves. To the contrary, it hugely reinforces the case for giving overwhelming priority to their well-being as they envisage it. Gains by poor people should come first. When the objective is to enhance the well-being to which poor people aspire, the benefits from small changes can be large indeed.

Box 7.1 *The good life, caring for children*

To be well is when you have money, and you have a family and children. You need to have savings in order to be able to support your children till later on in life.

A young man, Bulgaria

A good life is to have enough food and clothing for my children. To educate them to be self-reliant when we get retired.

A man, Mitti Kolo, Ethiopia

The rich manage to send their children to school and also … to take their children to the clinic.

A man, Musanya, Zambia

To be well means to see your grandchildren happy, well-dressed and to know that your children have settled down; to be able to give them food and money when-ever they come to see you, and not to ask them for help and money.

An old woman from rural Bulgaria

Material well-being: having enough

> *But at least for each child to have a bed, a pair of shoes, a canopy over their heads, two sheets – not to sleep like we do on the ground.*
>
> Ana Maria, a poor woman, Esmeraldas, Ecuador

> *A poor person is a person who does not own anything that provides him with a permanent source of living. If a person has a permanent source of income, he will not ask for other people's assistance.*
>
> A poor woman from Sidkia, Egypt

Three aspects of material well-being that are repeatedly mentioned are food, assets and work.

Food

Adequate food is a universal need. In Malawi hunger is ranked as the number one problem by nearly every discussion group in the three urban and seven rural communities participating in the study. Elsewhere – across the range of countries – enough to eat every day is again and again stressed as a feature of well-being. In contexts as different as Bangladesh, Bulgaria and Zambia well-being included being able to have three meals a day, all year round. Food security too is a critical component, with the number of months of food security given frequently as a criterion for ranking well-being, particularly in Vietnam.

Assets

For those living in rural areas secure tenure of adequate resources, especially land, is another nearly universal criterion of well-being. This often includes ownership of livestock. In urban areas the parallel needs are savings and capital, and access to consumer goods. In urban Ghana well-being is identified with capital to start a business. The need for housing – as well as furniture, utensils and tools – is also a virtually universal aspect of well-being and sometimes poor people describe a 'house that should not let in the rain'.

Work

Work to gain a livelihood is a nearly universal aspiration among participants. Money itself is mentioned less frequently than one might expect and, when mentioned, it is implied by other aspects of well-being such as the ability to find paid work to obtain money, to buy clothes and to pay for health treatment and school expenses. A poor man in Thompson Pen in Jamaica says, 'Work makes all the difference in the world. I feel bad, miserable, sick, and can't take doing nothing. My wife, at 78, is still working. My dream is a little work to make ends meet.'

In rural areas work takes many forms; it is usually agricultural and linked with land. In urban areas it means a steady job, which is stressed again and again by those who are without work or who are striving to make a livelihood through casual labour or informal and illegal activities. Whether it is Malawi, where one idea of well-being is both husband and wife working, or Russia, where participants stress the importance of wages that are regularly paid, the desire is for productive work to provide an adequate and secure livelihood.

Bodily well-being: being and appearing well

Material well-being is rarely mentioned without other critical aspects of a good life. These include the bodily well-being of health and appearance, as well as a good physical environment.

Almost everywhere, health and access to health services – whether informal or formal – are important. A healthy and strong body is seen as crucial to well-being – not just for a sense of physical well-being in itself, but as a precondition for being able to work. A person who is sick and weak cannot work or cannot work well.

For some, especially for girls and young women, the importance of appearance – of both body and clothing – comes through forcefully. Quality of skin is often referred to. In Muchinka in rural Zambia the bodies of the better off are said to 'look well'. For urban poor people in Jamaica criteria for well-being include 'skin tone looks balanced' and 'looking well fed'. In Gowainghat, Bangladesh clothes, oil for the hair and soap are important to young women. Across cultures and contexts being able to dress well and appear well is repeatedly stated as part of a good quality of life.

The third dimension of physical well-being is physical environment, with well-being in Accompong, Jamaica associated with, for example, 'the fresh air in the hills of Cockpit County'. The aspect of physical environment, however, is more often used in a negative context and is described, for example, as the bad experiences of living in 'the places of the poor'.

Social well-being

Social well-being includes care and well-being of children; self-respect and dignity; and peace and good relations within the family, community and country.

Being able to care for, bring up, marry and settle children

In Nigeria, of the 48 aspects of well-being identified, no fewer than eight of them refer to children. Having happy and healthy children, feeding them, clothing them, being able to take them for treatment when sick, and being able to send them to school and pay school bills are common concerns strongly expressed. In Bangladesh households that are financially well off are those that can afford clothes and education for their children.

To be able to marry and settle children is a frequent aspiration. In Malawi and Uzbekistan wedding ceremonies conducted in good style are important. In Ampenan Utara, Indonesia one of the criteria for differentiating well-being groups is the ability to meet the costs of children's weddings: the top group has no problem; the second group can meet the cost; the third has to become indebted to meet the costs; and the issue for the bottom group is simply not mentioned. Landless women in Dorapalli in India identify a major impact of poverty as 'difficulty in marrying girl children'. In Eil-bil-ille, Somaliland the well off are those who can afford marriage-related costs and who always marry at an early age.

Self-respect and dignity

Self-respect and dignity, as described by poor people, means being able to live without being a burden to others; living without extending one's hand; living without being subservient to anybody; and being able to bury dead family members decently. In Nigeria this includes being listened to, being popular and being able to fulfil social obligations and to help others.

Peace, harmony and good relations in the family and the community

Many poor people consider the absence of conflicts essential for family and social well-being. In Ghana this is expressed as unity in the household or community. In Uzbekistan it means peace and calm in the family, in the country and in one's own community.

Good relations extend to social cohesion and support, and to helping one another. In Vietnam near Ha Tinh poor people state their priorities as being able to 'encourage people to visit, support and give presents (show feelings in general) to households dealing with crises and during the holidays'.

Security

Security includes predictability and safety in life and confidence in the future.

Civil peace

A group of elderly residents of Ak Kiya in the Kyrgyz Republic comment, 'Among all well-being criteria, peace is the most important one. Now there is war in Yugoslavia and in other countries. God willing, it would not happen here. As they say, "be hungry but live in peace".' Even in contexts without recent experience of civil conflict or war, such as this one in the Kyrgyz Republic, civil peace was often ranked high. Peace – the absence of war, violence and disorder – is the most important component of well-being for those living in the context of recent war or disorder.

A physically safe and secure environment

Well-being means not being vulnerable to physical disasters, threats and discomforts that are so typical of the places of poor people. These included floods in urban Argentina and rural Bangladesh, wild animals in Sri Lanka and India, water pollution from industry in Bulgaria, the disaster from the Aral Sea in Uzbekistan, and air pollution from industry in Olmalyq, Uzbekistan. These are named among many other physical, often seasonal, threats.

Personal physical security

'Here we live with our door open', report participants in rural Argentina. A man in Jamaica says that 'this is a ghetto community, but you don't have any violence; you can walk (around) here any hour of the night and no one is going to harm you'. Again in Jamaica, the relaxed atmosphere and the high level of personal safety in the countryside are valued.

Lawfulness and access to justice

Refugees in a Russian city who survived the horror of a civil war and genocide and who were objects of constant abuses describe 'peace' and 'the absence of constant fear' as the main prerequisites of a good life. Lawfulness and access to justice are widely seen as aspects of well-being, particularly in Nigeria. Security from persecution by the police and other powers that be is a priority for many, especially for urban vendors.

Security in old age

Particularly for older people, security and support in old age are a primary concern. An old woman in Khaliajuri, Bangladesh says that, for a good quality of life, a son must not sever the family bond after marriage and he must provide food to his mother.

Confidence in the future

The good life is also frequently defined as being able to look forward to the future. Especially in countries like Bosnia and Herzegovina and Russia that have experienced recent national traumas participants value being able to have confidence in a stable and predictable future. They say that they once had this, but that it is now only experienced by a few rich people.

Freedom of choice and action

The research team from Brazil puts it like this:

> People tended to equate poverty with powerlessness and impotence, and to relate well-being to security and a sense of control of their lives. A woman from the community of Borborema established a connection between power and control, and well-being. She argued, 'The rich one is someone who says, "I am going to do it", and does it.' The poor, in contrast, do not fulfil their wishes or develop their capacities.

Freedom of choice and action extends to having the means to help others. Being able to be a good person is a feature of the good life that poor people often highlight. A young man in Isla Trinitaria, Ecuador wants to be able to buy clothes for his sisters. In Malawi a good characteristic of one high category of well-being was to love everyone and help others when they have problems. Well-being is quite frequently linked with moral responsibility, with having the wherewithal to help others, and with having enough money to be able to give to charity or a religious organization.

What people say they wish to be able to do covers a huge range: to gain education and skills; to have mobility and the means to travel; and to have time for rest, recreation and being with people – among others. Underlying all of these – and the material, physical, social and security dimensions – is a fundamental aspiration. Participants in many contexts say that they want to be able to make choices, to decide to do basic things without constraint, to live in a predictable environment and have some control over what happens.

Diversity by context and person

For all of these commonalities, there are differences of aspiration and of concepts of well-being. They vary by continental region, by rural and urban areas, by livelihood, by age and by gender.

The contrasts are perhaps not surprising, but listing a few of those that are more striking can make and illustrate the point without any attempt to be comprehensive:

- In Eastern Europe, Central Asia, Bulgaria, the Kyrgyz Republic, Russia and Uzbekistan, well-being is frequently defined nostalgically as the 'normal' condition, meaning before the end of communism. In Russia well-being criteria are taken from the past and not the present.

- Among pastoralists, whether Somalis in Somaliland or Kalmyks in Russia, well-being is often intimately linked with animals.
- Poor rural people emphasize land and livestock, farming capital and inputs for livelihood activities, and being able to farm on one's own.
- Poor urban people repeatedly emphasize employment, a job, infrastructure, housing, security of tenure and physical security. They sometimes have higher material aspirations for consumption goods than rural people. In one urban site in Malawi participants say that well-being entails leading a European (Western) life (*moyo wachizungu*), having houses to rent out to others, having decent and well-paying jobs and having very good houses with electricity.
- Women tend more often than men to mention peace in the family; good social relations in the community; adequate and nutritious food; good drinking water; being able to bring up children in good conditions, keep them healthy, and sending them to school; and not being maltreated in the family.
- Men tend more often to mention material productive goods, and time to relax. There are exceptions to these generalizations, and there is a danger of over-stereotyping gendered priorities and values, especially at a time when change in gender roles in many places is rapid.
- The views of some poor children were asked. In Chittagong, Bangladesh, according to children, well-being means having neat and clean surroundings, with facilities for education, being able to play freely, living in a building, having good food (fish, meat, vegetables, etc.), going every morning to madrasa (traditional Muslim school), and everybody living in harmony. Peace and harmony in the family and in society are important to children.

Wealth and well-being are different

In discussions on criteria for a good life, the researchers report:

- 'The group of young people underscored the need to have a family, to feel supported and understood.' – According to a youth group in Barrio Universitarios, Bolivia
- In Bulgaria, 'wealth and well-being are not identical, for the rich have money but don't have security, nor are they respected by the community. Ill-being is, however, identical with poverty: this is "our situation".'
- In Russia, 'the life of the well-to-do people was never called a "good life". Ultimately, when both the younger and older participants talked about the well-to-do people, they would never call their life a "good" one.'

Good living or well-being in Zambia, 'can mean being liked, but also can make others jealous and bring hatred and death'. Participants repeatedly distinguish between wealth and well-being. Those who are wealthy are by no means always in the top category for well-being. For example, a widow who is rich might not be put in the top well-being category because widowhood is a bad condition.

The wealthy can be generous and good, but often they are seen in a bad light. A 54-year-old man from Kok Yangak in the Kyrgyz Republic says:

> One can make a fortune, but if it has negative effects for the rest of the community, such wealth gives just an illusion of well-being, because it does not do any good for people. If somebody's well-being is based on the ill-being of others, it is not a true well-being. There are rich people in the village. They made their fortune by selling alcohol and vodka. The community does not like these people, because their prosperity is only possible due to the growing problem of alcoholism in the village.

In contrast, poverty and non-material well-being can sometimes be found together. In rural Accompong in Jamaica the researchers write that 'the lives of all citizens are impacted by this peace within the neighbourhood. Despite hard times and obvious poverty among most of the households an open welcome and hospitality to visitors and strangers to the community gives a distinct feeling of well-being and a good quality of life.'

Part II. Ill-being: The Bad Life

> *The family was housed in a thatched hut and there was no way that they could have two square meals a day. The lunch would be finished by munching some sugarcane. Once in a while they would taste 'sattu' (made of flour), pulses, and potatoes, etc., but for special occasions only. During the rains the water used to pour down the thatched roof and the family would go to seek cover in the corners to avoid getting wet. Their clothing would be of coarse material and they would content themselves with one or two pairs of clothes for a year. The wages then used to be paid as 1kg of grain per day. After three years of marriage, unable to bear the harassment of the mother-in-law, both Nagina Devi and her husband separated from her.*
>
> **A poor mother, Manjhar, India**

Ill-being and the bad life bring with them different sorts of bad experience. These are many and interwoven. Some correspond to the opposites of the clusters of well-being: lack and want are material; hunger, pain, discomfort, exhaustion and poverty of time are physical; bad personal relations, exclusion, rejection, abuse, isolation and loneliness are social; vulnerability and fear relate to insecurity; and helplessness, frustration and anger reflect powerlessness. It is also striking, though, how much of the bad life they miss, for there are others that flow from and feed them: loss, anguish, grief, humiliation, shame, and persistent anxiety, worry and mental distress. Box 7.2 features selections from poor people's definitions and criteria of ill-being.

Box 7.2 *Expressions of ill-being*

The words and expressions used for the bad life are naturally different in different language groups, countries and continents. A selection gives a sense of the range.

Ill-being and well-being have close equivalents in Spanish-speaking Latin America – *malestar* and *bienestar*. *Malestar* is a common word in Spanish, meaning a sense of unease or discomfort, which can be physical, social or psychological. It is not a synonym for poverty (*pobreza*). In urban Argentina, the words *situatión crítica* (critical condition), *vida complicada* (a complicated life) and *malaria* (situation where everything has gone wrong, total scarcity) are also used.

In Bolivia, *tristeza* (sadness), the opposite of *felicidad* (happiness), is used for ill-being, based on pictures of a sad face and a happy face, to which participants were invited to react.

In Malawi, *ukavu* means a state of constant deprivation. It is explained that households described in this group lack peace of mind because they are always worried about how to make ends meet. In most *ukavu* households, couples quarrel and fight a lot because they desire good lifestyles (*umoyo uwemi*), but they lack the means. 'It is not surprising that most men from these households are drunkards because they drink to forget home problems.'

Women from Mbwadzulu village in Malawi say that they consider it ill-being when 'people sit on the floor … people going to their gardens without taking any food … they have no latrines; they cook under the sun [have no kitchen], have no pit latrines, no change house [bathing place outside the house, constructed from grass] and no plate drying rack'.

In Buroa, Somaliland extreme ill-being is defined as the experience of war and famine.

In India, the word *dukhi* (and in Bangladesh *asukhi*), the opposite of *sukhi*, is close to ill-being, unhappiness, a bad condition of life in terms of experience, whether material, social or psychological.

In Chittagong, Bangladesh, ill-being is *asukhi* (unhappy) or *kharap abstha* (bad condition), the opposite of *bhalo abstha* (good condition).

In Bulgaria, one aspect of ill-being is a pervasive sense of loss, of moving backward in time to an earlier century – from cultivation by tractors to having to cultivate by hand, from buying soap and bread to having to make and bake your own. This is described as going wild (*podivyavane*), being obliged to work in a manner considered humiliating, uncivilized and inefficient.

Box 7.3 *The Bad Life in Ethiopia*

The following are literal translations of phrases used by poor men and women in Ethiopia to express their state of ill-being.

'We are left tied like straw'
'Our life is empty; we are empty-handed'
'Living by scratching like a chicken'
'What is life when there is no friend or food'
'Life has made us ill'
'We are skinny'
'We are deprived and pale'
'We are above the dead and below the living'
'Hunger is a hyena'
'The poor is falling, the rich is growing'
'A life that cannot go beyond food'
'We simply watch those who eat'
'Difficulties have made us crazy'
'We sold everything we had and have become shelter-seekers'
'It is [like] sitting and dying alive'
'My relatives despise me and I cannot find them'
'Life is like sweeping ash'
'From hand to mouth'
'A life that is like being flogged'
'A life that makes you look older than your age'
'Just a sip and no more drop is left'
'If one is full, the other will not be full'
'Always calf, never to be bull'
'We have become empty like a hive'

The multidimensionality of ill-being

As with well-being, participants describe ill-being as multidimensional. The most frequently mentioned dimensions of ill-being correspond closely to dimensions of well-being. The bad life is marked by many bad conditions, experiences and feelings. Box 7.3 illustrates the range of expressions that poor men and women from Ethiopia used to describe the bad life.

Material lack and want

Food

The most frequently mentioned want or lack is food. In every country poor families report that they miss meals. They often only eat once a day and sometimes have nothing for days on end. A saying in Ethiopia is, 'If one eats breakfast, there is no supper.' Hunger is highly seasonal in rural areas. In urban Russia it peaks towards the end of the month, before pay, when there can be days with an absolute lack of food. In many rural areas the poorest people rely on wild foods. Provision of food for children is a constant worry for parents, who themselves stint and starve. A mother in Nuevas Brisas del Mar, Ecuador says, 'In the last two years our children leave for the school without having coffee. Sometimes I have some money but if I fix them some breakfast there is not enough for lunch.' Urban starvation is less dramatic or obvious than that in rural areas, but poor people in Jamaica say it is more prevalent. In urban areas in countries that have undergone severe restructuring crises, study teams were shocked to learn of a quiet, hidden urban starvation. Some who starve are too proud and decent to beg or steal. In Ivanovo, Russia, 'a woman told us that sometimes she did not have food for several days and was only drinking hot water and lying in bed so as not to spend energy'. In Ethiopia a 30-year-old married man in Kebele 10 says, 'We eat when we have, and we go to bed hungry when we don't.'

Livelihood, assets and money

Uncertainty of livelihood sources and employment is virtually universal. Returns to work are low. Casual labour is both uncertain and badly paid. Insecurity from lack of assets and money is often mentioned, but more often implied. Money is needed for access to many services, especially health, education and transport; for bribes and fines; for daily necessities and often subsistence; for social occasions; and for clothing. Poor, ragged, second-hand and worn clothing is repeatedly given as a mark of being badly off. High-interest debt is common. Many needs and wants trace back to the lack of money.

Housing and shelter

Virtually everywhere, shelter and housing are a source of discomfort and distress. Shacks, huts, houses or tenements are small. Many people crowd into small spaces. Possessions are insecure. Huts and shanties leak and flood, fall down, blow down, burn down or are knocked down. People have to stand when the ground gets wet. Dirt, filth and refuse are always there. Urban sanitation is often non-existent or disgustingly bad. Sewers – where they exist – sometimes overflow and flood into huts, and health suffers as a result.

Physical ill-being

Hunger, pain and discomfort

The physical ill-being of hunger and sickness, and the pain, stress and suffering they bring, are a common theme. Women in a group in Nigeria do not have sufficient breast milk to feed their babies. In Bedsa, Egypt an older man says, 'Lack of work worries me. My children are hungry and I tell them the rice is cooking, until they fall asleep from hunger.' In Ethiopia there is 'burning hunger' and 'fire of hunger'. Poor people are more often sick and injured, and are often sick for longer, and treated, if at all, later than the non-poor. The reasons are many. Sickness itself is a frequent cause of suffering and impoverishment, leading to physical weakness, dependence and disability. Finally, poor people live in discomfort, in unhygienic, dangerous, dirty, badly serviced and often polluted environments where they are vulnerable to many physical shocks, stresses and afflictions.

Exhaustion and poverty of time

The sheer exhaustion and lack of energy many poor people experience is easily overlooked. For many, their body is their main or only asset. It is uninsured. Shortage of food and sickness not only causes pain, but also weakens and devalues the asset. Those short of food are badly stressed by hard work. There are 'lazy' poor people, but inactivity is often conservation of energy. Poor people are often described as tired, exhausted and worn out.

The increasing burdens of their expanded roles are driving many women deeper and deeper into physical exhaustion. These burdens also expose them to 'time poverty', meaning that they have little or no time to rest, reflect, enjoy social life, take part in community activities or spend time in spiritual activities. Whereas men are often increasingly out of work, women are under more pressure.

Bad social relations: exclusion, rejection, isolation and loneliness

Exclusion takes many forms. Ignorance of or lack of fluency in a dominant majority language can be excluding. Minority groups around the world share the linguistic exclusion of women in Guadalupe, Bolivia who do not participate in public community activities because they feel embarrassed to speak their native language, Quechua. Denial of education can be excluding. The parents of Um Mohamed, a girl in El Gawaber, Egypt, forced her to leave school: 'They sentenced me to death when they did that.' In Brazil there is exclusion when parents try to enrol their children in public schools and are unable to find places for them.

Rejection is associated with poverty in many ways. The extremely poor are often rejected, even by those who are also poor. Two other forms of rejection are the abandonment of children and of old people. The feelings of rejection, isolation and loneliness are most often cruelly inflicted on those who suffer most in other ways.

Loneliness and lack of social support are no longer an uncommon experience of poor people generally, particularly the elderly. Those with little social support are described as being 'poor in people'. In rural Bulgaria, an old woman says, 'Young people have nothing to do here. You can't imagine how I feel, as lonely as the dawn, but I was the first to prompt them to move to the city. I would have felt even worse watching them waste their lives here.' Old men in Mbamoi, Nigeria say, 'We poor men have no friends. Our friend is the ground.' This isolation is most acute for those who are very poor indeed and for those who are too weak to be able or to wish to assert themselves, especially the old. In Nuevas Brisas del Mar in urban Ecuador, where the team shared a meal with participants, an old man who had been present for three days and had hardly taken part at all was identified as 'the voice of those without voice, the voice of hunger'.

Self-exclusion occurs when inclusion is seen as dangerous or bad, and is a cost of a violent or abusive environment. Says a woman in Dock Sud, Argentina, 'Now I am with my grandson. He is seven and the teachers in kindergarten tell me I have to let him be with other boys, but what for? To be a drug addict when he grows up? Here there are kids that are eight years old who do drugs, and after that they start to rob. No, I'd rather see him alone, isolated, like they say in school, but I'd rather have him at home with me; I take care of him.'

Self-exclusion also occurs for reasons of shame. A poor person may not be invited to a wedding. If invited, a poor person may decide not to go because of being unable to appear and behave appropriately. Many of the self-excluded are the 'invisible poor', especially the 'new poor' who will not confess that they are poor. In a city in Bulgaria a poor man comments, 'There was a man in our apartment building. A silent, shy fellow, always very neatly dressed. They found him dead in his apartment. The doctor said that he had become so feeble that he died of a common cold; they found just a piece of stale bread in his flat. It's a pity we never spoke with him. He had dignity, that fellow.'

Insecurity, vulnerability, worry and fear

> *There's great insecurity now. You can't make any plans. For all I know, tomorrow I might be told that we'll be laid off for a couple of months or that the factory is to shut down. We work three days a week even now, and you're in for a surprise every day.*
>
> Participant, discussion group of men and women,
> Kalofer, Bulgaria

> *I am going to be poor and even hungry if I cannot labour in the coming years due to old age.*
>
> A resident, Ha Tinh, Vietnam

Insecurity and vulnerability are deeply embedded in the bad life. Insecurity comes through exposure to mishaps, stresses and risks – to dangers in the physical environment, in society, in the economy and in the administration and legal systems. Vulnerability comes because poor people are defenseless against damaging loss. Together these generate worry and fear: of natural disaster, of violence and theft, of loss of livelihood, of dispossession from land or shelter, of persecution by the police and powers that be, of debt, of sickness, of social ostracism, of the suffering and death of loved ones, of hunger and of destitution in old age.

Lack of confidence is frequently mentioned as a result of poverty. In Bosnia and Herzegovina, the inability to find a job makes people feel worthless to themselves and their families.

Powerlessness, helplessness, frustration and anger

Again and again, powerlessness seems to be at the core of the bad life. In Russia it is articulated as a complete sense of political impotence. More generally, powerlessness is described as the inability to control what happens, the inability to plan for the future, and the imperative of focusing on the present. In Zawyet Sultan, Egypt the condition known as *el-ghalban* and *ma'doom el hal*, words used for the poorest, mean helplessness and having no control over sources of one's living and therefore no control over one's destiny.

Time horizons are then short. Young people in Kalofer, Bulgaria say, 'Each day is unpredictable – you can't make any plans, don't know what you're in for tomorrow.' The sense of impotence is compounded when the future is seen as getting worse. Urban youth in Esmeraldas, Ecuador are reported as saying, 'You can't think of the future because you can only see how to survive in the present.' The report continues to say that everybody in the group agrees that in the future there is only going to be more poverty. At this stage the facilitators had to stop the meeting because the youth got fed up.

Poor people want to be able to take the long view, but they cannot. Having to live 'hand to mouth' is not a choice, but an immensely frustrating necessity. The experience is daily anxiety, and having to eat the moment they receive food or money.

Worry about the future, especially the future of children, coexists with concerns for the immediate present. According to the report of an interview with a woman in Pedda Kothapalli, India, 'She is worried about the future of her children and the struggles they have to face once they grow up. Her immediate concern is to which house she should go for a loan of some food grains for their food that day.'

Part III. Psychological Experience of Well-being and Ill-being

The experience of well-being and ill-being is inextricably psychological. The dimensions of good and bad quality of life contribute to and are part of good and bad states of mind and being.

The experience of well-being: peace of mind, happiness and harmony

> *Being well means not to worry about your children, to know that they have settled down; to have a house and livestock and not to wake up at night when the dog starts barking; to know that you can sell your output; to sit and chat with friends and neighbours. That's what a man wants.*
>
> **A poor man, Bulgaria**

Interwoven with other dimensions of well-being – material, bodily, social, security, and freedom to choose and act – is psychological well-being. This is variously expressed as happiness, harmony, peace, freedom from anxiety and peace of mind. From Novi Gorodok, Russia comes, 'Well-being is a life free from daily worries about lack of money'; from Gowainghat, Bangladesh, 'to have a life free from anxiety'; from Nova Califórnia, Brazil that quality of life is 'not having to go through so many rough spots' and 'when there is cohesion, no quarrels, no hard feelings, happiness, in peace with life'; from Nigeria, 'well-being is found in those that have peace of mind, living peacefully. It is to be filled with joy and happiness. It is found in peace and harmony in the mind and in the community.'

For many, too, a spiritual life and religious observance are woven in with other aspects of well-being. Poverty itself could get in the way. An old woman in Bower Bank, Jamaica says, 'I got up this morning and all I want to do is read my Bible, but I share a room with my son and my grandchildren and all they do is make noise, I can't even get a little peace and quiet.' In Padamukti, Indonesia being able to make the pilgrimage to Mecca means much, as does having *sholeh* (dutiful and respectful) children who will look after their parents in old age and pray for them after they are dead. In Chittagong, Bangladesh part of well-being is 'always [being] able to perform religious activities properly'. For older women in Cassava Piece, Jamaica, their church gives them a spiritual uplift and physical support. The importance to poor people of their sacred place – holy tree, stone, lake, ground, church, mosque, temple or pagoda – is repeatedly evident from their comparisons of institutions in which these frequently ranked high, if not highest.

The experience of ill-being: humiliation, shame, anguish and grief

Experiences of ill-being can be seen to combine and to compound each other in bad states of mind and being. Some connections stand out strongly. It is striking how often participants raise aspects of mental distress when describing the effects of poverty. Women in Tabe Ere, Ghana, for example, connect poverty, anxiety, begging, shame, isolation and frustration. They explain that poverty creates 'too much pressure on individuals and often renders a person mad with worry and anxiety'. Begging is seen as a degrading activity, which brings about insult and disgrace to the family. This results in shyness within the community that in turn leads to frustration in life. Participants in different countries speak of mental stress and breakdown, depression, madness and suicide, together the antithesis of the well-being of peace of mind.

Humiliation, shame and stigma

The stigma of poverty is a recurring theme. As a consequence, poor people often try to conceal their poverty to avoid humiliation and shame.

One deeply felt deprivation is not being able to do what is customary in the society. Frequently cited, for example, is not being able to entertain visitors or enjoy social life. In Malawi, there is shame from not having toilets for visitors, or money to buy a coffin for burying a relative. In Beisheke in the Kyrgyz Republic, an elderly village man says, 'In the Soviet times we had no idea what poverty was about, we were equally wealthy, and now we feel humiliated because we cannot afford to receive guests in our houses, or visit friends and relatives. It was for that reason that we could not invite you [the study team] to our house when we first met.'

Poor people sometimes feel shame and anger in accepting or having to accept alms or special treatment. In India this does not appear to apply to programmes that give poor people well-recognized rights, like the government ration shops. Similarly in Viyalagoda, Sri Lanka those who are poorer say it is a great help that their children are getting school books and uniforms: earlier their uniforms had been yellowish in colour after several washings and they were ashamed. Now their children can sit together with others without any shame. By giving books and uniforms instead of money, the government has done a great thing.

By contrast, in Novy Gorodok, Russia even the most needy are humiliated to take poor quality goods provided for them by the welfare office. One participant commented, '[The food] is spoiled, and at prices higher than in the shops. I took a sack of flour once, and there were worms.' Sexual abuse, with its physical violence as well as humiliation, is a greater threat for those in poverty, especially for women, given the places in which they live. In Dock Sud, Argentina most rapes are not reported because of shame. The same applies with sexual abuse, harassment and exploitation. In Bulgaria, a participant in a discussion group of women says, 'Only young girls aged under 20 or 22 can find a job. If they are 25 or older, nobody wants them. I can do the job of a waitress perfectly well, but the boss wanted somebody who'd do another job for him just as well.'

Poor people often experience humiliation in their encounters with officials and those delivering services. In Chittagong, Bangladesh discussion groups report that '*thana* [administrative unit between the village and district level] officials are corrupt, unaccountable "to anyone" for their dishonest acts and only show "special respect" to the rich'. Colour prejudice is mentioned in Brazil and Ecuador.

Appearances and clothes, as well as being an important part of physical well-being, are mentioned as important for self-respect and, conversely, they can be a source of shame. In Etropole, Bulgaria 'people who cannot afford warm clothes for the winter go to work. Then they come back and stay at home under a pile of blankets, shivering with cold. They don't go out. They are ashamed to meet other people. If they run into a friend and are invited for a drink they must refuse. So they would rather not go out at all.' In the Kyrgyz Republic a middle-aged woman says, 'My daughter came from school crying. Somebody at school called her a beggar, because she was wearing the jacket that we received as humanitarian aid. She refused to go to school.'

Anguish, loss and grief

Anguish, loss and grief are implicit in so many life histories of poor people, and these speak through the pages of the case studies. Sickness and death are very frequent. Anguish, when loved ones are sick and treatment is known but cannot be afforded, is found in all societies, and not only among poor people. For many participants, though, this experience is common, acute and agonizing, and for many it comes more and more often. Especially in Africa, the rising incidence of HIV/AIDS and malaria has combined with shrinking access to affordable treatment.

Psychological ill-being is marked where there has been a sharp decline in the levels of living and well-being, and where people from former middle classes have become impoverished. This is most notable among the former middle classes in Bosnia and Herzegovina, Bulgaria, the Kyrgyz Republic, Russia and Uzbekistan who are now the 'new poor'. The Bosnia and Herzegovina National Report speaks of 'psychological ill health' in all the communities. In one, the psychological effects of economic misery are listed as 'one's psychological health, distancing oneself or withdrawing from others, tensions between people, irritability, insecurity, apathy, nervousness, monotony, and dissatisfaction'.

The burden of war and civil disturbance for those caught up in them is expressed in Bosnia and Herzegovina, for example, in Bijeljina, especially by anguished women whose husbands and sons were fighting. The trauma of refugees and others who have suffered from violence is an extreme form of mental distress. Instant impoverishment often combines with fear and the anguish of loss, especially when family members are at risk or have been killed. Just how terrible the effects can be is expressed by one older woman in Bijeljina: 'I had to send a husband and two sons to the front lines and wait for them to return – or not. I did not think about eating, sleeping, dressing or anything. I would lie down and awake in tears. What have we lived to experience?' For her, spiritual poverty is more devastating than her material poverty: 'You can never recover from spiritual impoverishment.'

In the former Soviet region, participants express a profound sense of loss regarding their earlier level of living, when they had guaranteed jobs, free education and health care, social safety nets and recreation. Nostalgia is too weak a word to describe what they feel. At the same time, as with other loss and bereavement, they know it has gone forever. 'Those who don't feel sorry about the collapse of the Soviet Union have no heart, but those who think that it may be restored have no brain', says an elderly man in the Kyrgyz Republic.

Bald figures of life expectancy do not show what they mean in human terms. The horrors, separations and losses in war and civil disorder have become the commonplaces of journalism and television. The avoidable loss of loved ones in the quiet crisis of poverty is on a much larger scale, but unseen. The experience is worse when the bereaved are denied the last rites, grieving and consolation, which are customary and due in their society, because of the simple fact of their own poverty.

The ill-being of children

Parents are again and again preoccupied with securing a good life for their children. So the children's own experience and view of the bad life have a double importance: for themselves as children and for adults as their parents and guardians.

Table 7.1 *Dislikes and fears of children in Ho Chi Minh City, Vietman*

Girls	*Boys*
• Having to drop out of school, special classes closing down • My forthcoming school exams • Fighting in the community • Homeless people being cold during storms • Drug addiction in the neighbourhood • Gambling • Loan sharks • Leaking roofs in the neighbourhood • Flooding of the neighbourhood and houses • A dirty and polluted neighbourhood • That our house might collapse • Friends being too poor to afford new clothes • Neighbourhood children dropping out of school and working hard • Drunken men beating up their wives and children • Quarrelling between my mother and father • That my mother works too hard • That my family might break up • Having no money to buy rice • Having no money to pay for rent or medical treatment • Having nobody to look after me if my parents are sick • Being robbed, break-ins and theft • Having our house and neighbourhood cleared away • The rich looking down on the poor people	• Sickness of teacher, causing class to close down • Failing to move up a grade; having to repeat a class • Sniffing heroin, drug addiction, young drug addicts stealing and robbing • Gambling • Fighting and quarrelling in the community • Robbery, especially of dogs • Street accidents happening to children • Neighbourhood fires • A dirty and polluted neighbourhood • Prostitution among young people in the community • Spread of AIDS • Sickness of my family members or mother • Fights and conflict between my mother and father • Divorce of my parents; family splitting up • My mother running off with another man • Sale of our house to repay a debt • Having our house demolished and cleared away • Having a roof that leaks • Having no house of our own; having to share a room with other families • Having no money • Being unable to get a job • Rich people scolding the poor people they hire • Richer families not allowing us to watch their TV • Rich people living in luxury, not helping poor people • Richer people looking down at us

In Ho Chi Minh City, Vietnamese children summarize their feelings about the consequences of being poor as deprivation and resentment (see Table 7.1). They resent that they cannot go to school or to the school they want, and that their parents have neither the time nor the money to take them on outings. Boys and girls over ten resent being scolded because of indebtedness and the failure to repay loans. The boys say that everyone in the family is working, but there is still not enough to eat; that they have to accept beatings from others and can do nothing in return; and that they are always blamed when something is stolen. Boys under ten cannot have a birthday party like other children. Girls under ten are teased by richer children because they are poor. And girls over ten resent having to agree with richer people and act as their inferiors, even if what they [the rich people] say is wrong.

The vivid directness of what girls and boys see and experience as the bad life is revealing. The Ho Chi Minh City report concludes that 'what the young emphasize more than any other group … is the effect of poverty on the family itself. They see poor families as tense, conflictual and subject to break-down.' It is perhaps no surprise that family harmony matters much to children, but worthy of note that they see a link between poverty and bad relations in the family. Also, both girls and boys mention the behaviour of the rich, and being looked on badly and being treated badly by them – something that adults, perhaps through prudence, mention only occasionally.

For their part, the parents' pain when they cannot provide for and look after their children is shown to be a big part of adult ill-being.

In Muynak, Uzbekistan in the extreme of distress, there is an ultimate way out: 'There are families who do not eat and drink in three days. People die of hunger. For example, Ayagan was a good guy. He could not provide his family with food, his children cried and then he shot himself.'

Reflections

In understanding what a good experience of life is, there is perhaps no end, no final answer. But if development is to enhance the well-being of poor people in their own terms, there is much to reflect on in what they say.

The discussions in Ethiopia generated the list of dire statements in Box 7.3. Yet one of the team leaders in Ethiopia, on approaching a very poor, remote community, heard singing and dancing. This can jolt us into recognizing that there are many good things, each in its own culture, which contribute to well-being: not only singing, dancing and music, but also festivals, ceremonies and celebrations; good things in their seasons; love, kindness and sacrifice; and religious and spiritual practices and experiences. But to many of those who are most deprived, these fulfillments are diminished or denied.

The overarching questions are then whether, where and why human well-being is being enhanced or eroded; whether for many millions the singing and dancing are dying or renewing; whether the conditions for material, bodily, social, mental and spiritual well-being are improving or getting worse; and above all how to enable poor people to gain for themselves more of the good life to which they aspire.

Who Will Feed China?

L. Brown

Overview: The Wake-up Call

We often hear that the entire world cannot reasonably aspire to the US standard of living or that we cannot keep adding 90 million people a year indefinitely. Most people accept these propositions. Intuitively, they realize that there are constraints, that expanding human demand will eventually collide with the Earth's natural limits.

Yet, little is said about what will actually limit the growth in human demands. Increasingly, it looks as though our ability to expand food production fast enough will be one of the earlier constraints to emerge. This is most immediately evident with oceanic fisheries, nearly all of which are being pushed to the limit and beyond by human demand. Water scarcity is now holding back growth in food production on every continent. Agronomic limits on the capacity of available crop varieties to use additional fertilizer effectively are also slowing growth in food production.

Against this backdrop, China may soon emerge as an importer of massive quantities of grain – quantities so large that they could trigger unprecedented rises in world food prices. If it does, everyone will feel the effect, whether at supermarket checkout counters or in village markets. Price rises, already under way for seafood, will spread to rice, where production is constrained by the scarcity of water as well as land, and then to wheat and other food staples. For the first time in history, the environmental collision between expanding human demand for food and some of the Earth's natural limits will have an economic effect that will be felt around the world.

It will be tempting to blame China for the likely rise in food prices, because its demand for food is exceeding the carrying capacity of its land and water resources, putting excessive demand on exportable supplies from countries that are living within their carrying capacities. But China is only one of scores of countries in this situation. It just happens to be the largest and, by an accident of history, the one that tips the world balance from surplus to scarcity.

Analysts of the world food supply/demand balance have recognized that the demand for food in China would climb dramatically as industrialization accelerated

Reprinted from Brown L. 2002. *Who will Feed China?* Earthscan, London. Chapters 1 and 2, pp23–43.

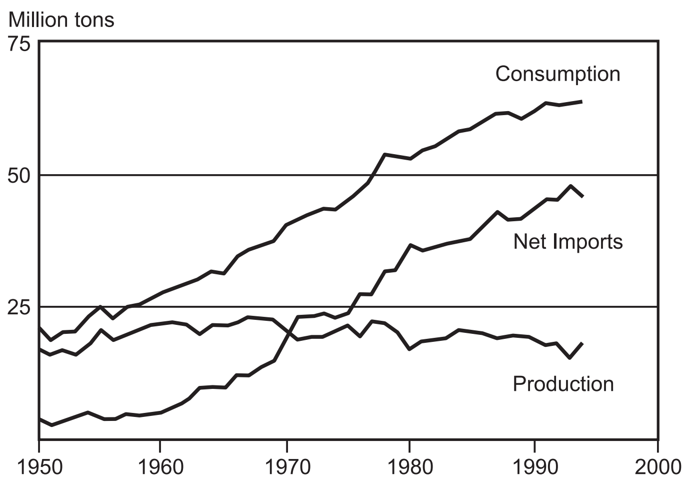
and incomes rose. They have also assumed that rapid growth in food production in China would continue indefinitely. But on this latter front, a closer look at what happens when a country is already densely populated before it industrializes leads to a very different conclusion. In this situation, rapid industrialization inevitably leads to a heavy loss of cropland, which can override any rises in land productivity and lead to an absolute decline in food production.

Historically, there appear to be only three other countries that were densely populated in agronomic terms before industrializing – Japan, South Korea and Taiwan. The common experience of these three gives a sense of what to expect as industrialization proceeds in China. For instance, the conversion of grainland to other uses, combined with a decline in multiple cropping in these countries over the last few decades, has cost Japan 52 per cent of its grain harvested area, South Korea 46 per cent and Taiwan 42 per cent.[1]

As cropland losses accelerated, they soon exceeded rises in land productivity, leading to steady declines in output. In Japan, grain production has fallen 32 per cent from its peak in 1960. For both South Korea and Taiwan, output has dropped 24 per cent since 1977, the year when, by coincidence, production peaked in both countries. If China's rapid industrialization continues, it can expect a similar decline.[2]

While production was falling, rising affluence was driving up the overall demand for grain. As a result, by 1994, the three countries were collectively importing 71 per cent of their grain. (See Figure 8.1.)[3]

Exactly the same forces are at work in China as its transformation from an agricultural to an industrial society progresses at a breakneck pace. Its 1990 area of grainland per person of 0.08ha is the same as that of Japan in 1950, making China one of the world's most densely populated countries in agronomic terms. If China is



Source: See endnote 3.

Figure 8.1 *Combined grain production, consumption and trade for Japan, South Korea and Taiwan, 1950–1994* to avoid the decline in production that occurred in Japan, it must either be more effective in protecting its cropland (which will not be easy, given Japan's outstanding record) or it must raise grain yield per hectare faster during the next few decades than Japan has in the last few – an equally daunting task, considering the Japanese performance and the fact that China's current yields are already quite high by international standards.[4]

Building the thousands of factories, warehouses and access roads that are an integral part of the industrialization process means sacrificing cropland. The modernization of transportation also takes land. Cars and trucks – with sales of 1.3 million in 1992 expected to approach 3 million a year by the decade's end – will claim a vast area of cropland for roads and parking lots. The combination of continually expanding population and a shrinking cropland base will further reduce the already small area of cropland per person.[5]

At issue is how much cropland will be lost and how fast. Rapid industrialization is already taking a toll, as grain area has dropped from 90.8 million hectares in 1990 to an estimated 85.7 million in 1994. This annual drop of 1.26 million hectares, or 1.4 per cent – remarkably similar to the loss rates of China's three smaller neighbours in their industrialization heyday – is likely to endure as long as rapid economic growth continues.[6]

China faces another threat to its food production that its three smaller neighbours did not. Along with the continuing disappearance of farmland, it is also confronted by an extensive diversion of irrigation water to non-farm uses – an acute concern in a country where half the cropland is irrigated and nearly four-fifths of the grain harvest comes from irrigated land. With large areas of north China now experiencing water deficits, existing demand is being met partly by depleting aquifers. Satisfying much of the growing urban and industrial demand for water in the arid northern half of the country will depend on diversions from irrigation.[7]

That China's grain production might fall in absolute terms comes as a surprise to many. This is not the result of agricultural failure but of industrial success. Indeed, China's record in agriculture is an exceptional one. Between 1950 and 1994, grain production increased nearly fourfold – a phenomenal achievement. After the agricultural reforms in 1978, output climbed in six years from scarcely 200 million tons to 300 million tons. With this surge, China moved ahead of the US to become the world's leading grain producer. (See Figure 8.2.)[8]

Another way of evaluating China's agricultural record is to compare it with that of India, the world's second most populous country. Per capita grain production in China, which was already somewhat higher than in India, climbed sharply after agricultural reforms were launched in 1978, opening an impressive margin over its Asian neighbor. (See Figure 8.3.)[9]

Between 1978 and 1984, China did what many analysts thought was impossible: in just six years, it raised annual grain production from roughly 200kg per person to nearly 300kg. At 200kg, almost all grain is needed to maintain a minimal level of physical activity; an additional 100kg a year opens the way for convert-

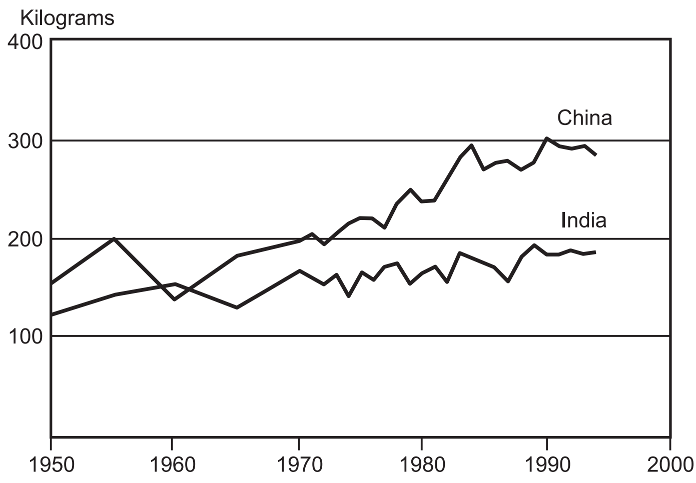
Figure 8.2 *Grain production, US and China, 1950–1994*



Source: See endnote 9.

Figure 8.3 *Grain production per person, China and India, 1950–1994*

ing some grain into pork, poultry and eggs. The immediate challenge facing China is not averting starvation, for it has established a wide margin between its current consumption level of 300kg and the subsistence level. Rather, the challenge is to maintain price stability in the face of soaring demand for food, driven by unprecedented advances in income.[10]

While China's food production capacity is starting to erode as a result of its breathtaking pace of industrialization, its demand for food is surging. The country is projected to add 490 million people between 1990 and 2030, swelling its population to 1.6 billion – the equivalent of adding four Japans. Because China's population is so large, even a slow rate of growth means huge absolute increases. Yet these increases are only the beginning of the story.[11]

Even as population expands, incomes are rising at an unprecedented rate. Economic growth of 13 per cent in 1992 and again in 1993, of 11 per cent in 1994, and of an estimated 10 per cent in 1995 adds up to a phenomenal 56 per cent expansion of the Chinese economy in just four years. Never before have incomes for so many people risen so quickly.[12]

This rapid economic expansion promises to push demand for food up at a record rate. When Western Europe, North America and Japan began establishing modern consumer economies after World War II, they were home to some 340 million, 190 million and 100 million people, respectively. By contrast, China is entering the same stage with a population of 1.2 billion and an economy that is expanding twice as fast. If its rapid economic growth continues, China could within the next decade overtake the US as the world's largest economy.[13]

Past experience has not prepared us well for assessing the scale of China's future food demand. Multiplying 1.2 billion times anything is a lot. Two more beers per person in China would take the entire Norwegian grain harvest. And if the Chinese were to consume seafood at the same rate as the Japanese do, China would need the annual world fish catch.

As incomes rise, one of the first things that low-income people do is diversify their diets, shifting from a monotonous fare in which a starchy staple, such as rice, supplies 70 per cent or more of calories to one that includes meat, milk and eggs. As consumption of pork, beef, poultry, eggs, milk and other livestock products increases along with income, grain requirements rise rapidly.[14]

In neighbouring Japan, the soaring demand for grain driven by prosperity combined with the heavy loss of cropland since mid-century pushed dependence on grain imports to 72 per cent of total grain consumption in 1994. These same forces are now at work in China. It is one thing for a nation of 120 million people to turn to the world market for most of its grain. But if a nation of 1.2 billion moves in this direction, it will quickly overwhelm the export capacity of the US and other countries, driving food prices upward everywhere.[15]

The first signs of a growing imbalance between the demand and supply for grain in China became evident in early 1994. In February, grain prices in China's 35 major cities had jumped 41 per cent over the same month in 1993. In March, driven by panic buying and hoarding, the rise continued unabated. In response, the government released 2.5 million tons of grain from stocks to check the runaway increase in prices. This calmed food markets, but only temporarily. By October, grain prices were 60 per cent higher than a year earlier. More grain reserves were released, and the government banned trading in rice futures on the Shanghai Commodity Exchange. Speculators were driving futures prices upward, leading to panic among urban consumers. The 1994 inflation rate of 24 per cent – the worst since modern China was created in 1949 – was largely the result of rising food prices.[16]

Resisting the import of grain throughout most of 1994, Beijing let prices rise as much as possible to encourage farmers to stay on the land. In recent years an estimated 120 million people, mostly from the interior provinces, have left the land and moved to cities in search of high-paying jobs. This rootless, floating population, roughly the size of Japan's, wants to be part of the economic revolution. As a potential source of political instability, these migrants are a matter of deep concern in Beijing. The government is trying to maintain a delicate balance, letting the price of grain rise enough to keep farmers on the land but not so much that it creates urban unrest that could lead to political upheaval.[17]

Leaders in Beijing are also trying to deal with massive unemployment and underemployment, with much of the latter masked by villagers eking out a meager existence on tiny plots of marginal land. Creating enough jobs to employ productively an estimated 800 million workers depends on maintaining double-digit or near double-digit rates of economic growth. The government opened the country up to foreign investment in part because it was the only way to get the capital and technology needed to achieve this vital goal.[18]

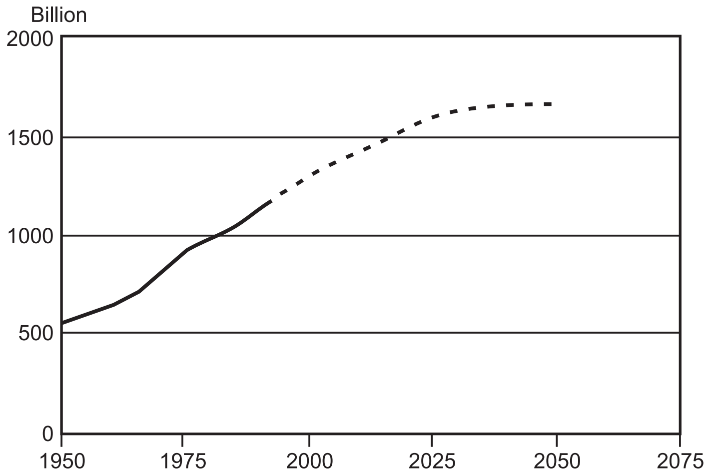
If China holds together as a country and if its rapid modernization continues, it will almost certainly follow the pattern of Japan, South Korea and Taiwan, importing more and more grain. Its import needs may soon far exceed the exportable supply of grain at recent prices, converting the world grain economy from a buyer's market to a seller's market. Instead of exporters competing for markets that never seem large enough, which has been the case for most of the last half-century, importers will be fighting for supplies of grain that never seem adequate.[19]

In an integrated world economy, China's rising food prices will become the world's rising food prices. China's land scarcity will become everyone's land scarcity. And water scarcity in China will affect the entire world.

In short, China's emergence as a massive grain importer will be the wake-up call that will signal trouble in the relationship between ourselves, now numbering 5.7 billion, and the natural systems and resources on which we depend. It may well force a redefinition of security, a recognition that food scarcity and the associated economic instability are far greater threats to security than military aggression is. The chapters that follow analyse this transformation, explaining why and how it is likely to come about.[20]

Another Half-billion

As Chinese leaders analysed future population, land and water trends some 20 years ago, they realized that they had to choose between the reproductive rights of the current generation and the survival rights of the next generation. What separates the government in Beijing from those in many other countries is that it is desperately trying to protect the options of the next generation, politically difficult



Source: See endnote 21.

Figure 8.4 *Population of China, 1950–94, with projections to 2050*

though that may be. This farsightedness and the political courage of the government of China deserve recognition.

In 1982, China's population reached 1 billion, making it the first member of an exclusive club. By 2017, its population is projected to reach 1.5 billion – equal to the world's entire population in 1900. Its demographic growth is then expected to slow and its population to peak at 1.66 billion in 2045, after which it should start to decline slowly. (See Figure 8.4.)[21]

Looked at in terms of the last four decades and the next four, the magnitude of China's population growth becomes clear. From 1950 to 1990, China added 571 million people. From 1990 to 2030, it is projected to add 490 million more. This anticipated addition reflects an impressive slowing in the rate of population growth, but it is still nearly a half-billion people. Stated otherwise, during the next four decades China will be adding an average of roughly 12 million people to the world annually.[22]

Many people think of Asia and Europe as having similar population densities, but in reality Asia has many more people per hectare of grainland than Europe does. The grainland per person in China today is roughly half that in France and it is inherently less fertile. The other difference is that Europe's population has stopped growing. Now that the growth in grain use per person that accompanied rising incomes has also come to an end, the demands made by the region's population on its land and water resources have stabilized. Europe is living well within its food production capability or, in ecological terms, its food carrying capacity. Indeed, it is producing a modest grain surplus.[23]

In geographic area, China and the US are essentially the same size. The big difference is that the western half of China is largely inhospitable to human habitation. Lacking basic life-supporting soil and water resources, it contains only a small percentage of the country's people.

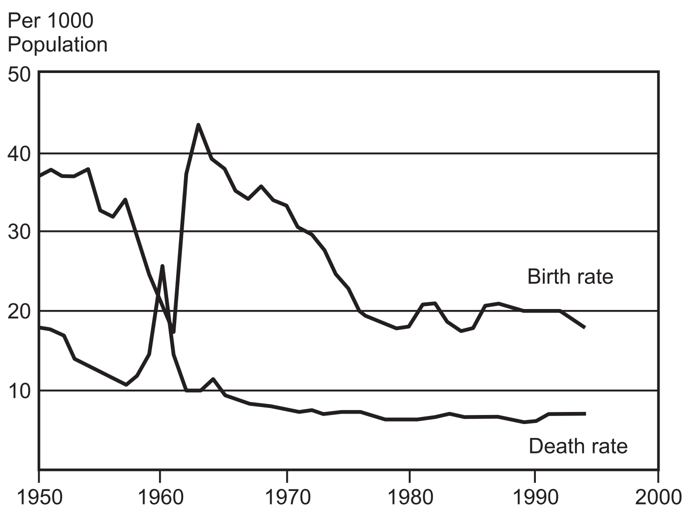
For China, where the opportunity for bringing new land under cultivation is limited by water scarcity, population growth has a double-edged effect. First, it is shrinking the cropland area per person, as a fixed area is divided among an ever larger number of people. At the same time, the new citizens bring demands for living space, which in turn generates pressure to convert cropland to residential purposes. Simply housing an additional 490 million people in the next 40 years will require an enormous area, some of which will be cropland.[24]

There is a certain fascination with the demographic trends and issues of China partly because of its sheer size. In addition, the chaos of the Great Leap Forward and the arithmetic of the resulting famine that was long concealed from the outside world have intensified interest in China's demographic history.

In the late 1950s, during the Great Leap Forward, millions of farmers were diverted to large construction projects, including roads, huge earthen dams and backyard steel furnaces. This movement of labour from agriculture led to massive food shortages. Official records now show that 30 million Chinese starved to death during 1959–1961. The demographic effect of the famine, however, extended far beyond these deaths.[25]

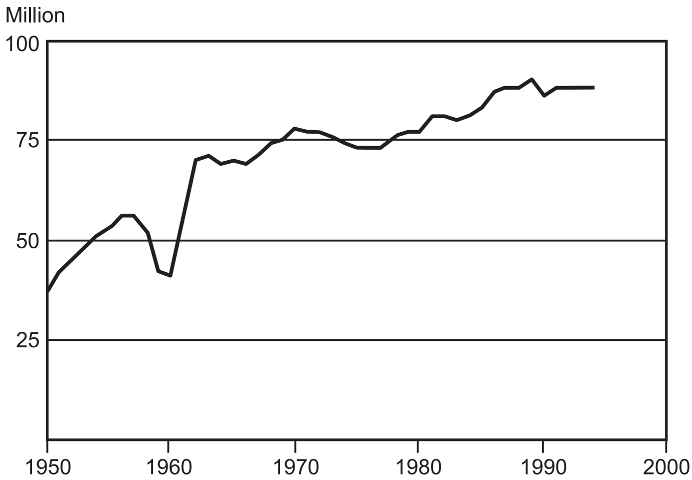
In populations that are near starvation, the frequency of intercourse decreases, sharply reducing the number of possible pregnancies. Beyond this, severely malnourished women cease ovulating, thus further reducing the number of pregnancies. Women who do conceive when they are severely malnourished often miscarry.[26]

During the heart of the famine in 1960, the number of deaths in China actually exceeded the number of births. The birth rate fell to 21 per 1000 population



Source: See endnote 27.

Figure 8.5 *Crude birth and death rates in China, 1950–1994*



Source: See endnote 28.

Figure 8.6 *Annual addition to world population, 1950–1994*

while the death rate climbed to 25 per 1000, leading to a decline in China's population for one year. (See Figure 8.5.)[27]

The drop was so steep that it markedly affected the number of people added to world population. (See Figure 8.6.) Between 1950 and 1957, that number was increasing steadily, climbing from 39 million to 57 million. It then began to drop, reaching a low of 41 million in 1960. As China recovered from the famine, the annual addition climbed sharply to 70 million in 1962, recovering the trend that had existed before the famine.[28]

The Great Famine of 1959–1961 left an indelible imprint on China's national psyche. John Bermingham, president of the Colorado Population Coalition, observes that 'just as an American generation was seared by the Great Depression and a German generation by runaway inflation, the Chinese have had a generation seared by famine'. These analogies help us understand the effect of the Chinese famine, but the latter was more traumatic simply because it was life-threatening for such a vast number of people.[29]

Like many governments, China was slow to recognize the population threat. Socialist ideology made it easy to dismiss the problem. As demographer Michael Teitelbaum notes, 'For Marx, the fact that people were producers as well as consumers meant that the resource limits emphasized by the classical economists could arise under capitalism, but not under socialism.'[30]

A quarter-century after the communist takeover in 1949, the government began to recognize population growth as a matter of concern. This occurred as part of the post-Mao reassessment in which projections of China's population growth were made. Much to the dismay of officials, based on an assumption of two children per couple, China could expect to add the better part of 1 billion people, adding the equivalent of an India to its existing population.[31]

As analysts attempted to calculate the consequences of population increase for cropland and water supply per person, and the availability of capital for creation of jobs, they realized that this was not a viable proposition. They were then confronted with one of the most politically difficult challenges for any government: the need to shift to a one-child family.

China faces some unique and difficult demographic issues. In contrast to Europe, there is no meaningful emigration safety valve. For countries such as England, Ireland, Germany, Italy and Spain, mounting population pressure during their early development translated into a steady flow of migrants, many of them bound for the New World. Today, there are more people of Irish extraction in the US than in Ireland. Similarly, there are more Spanish descendants in Latin America than in Spain. Indeed, the New World is populated largely with the demographic overflow of Europe.[32]

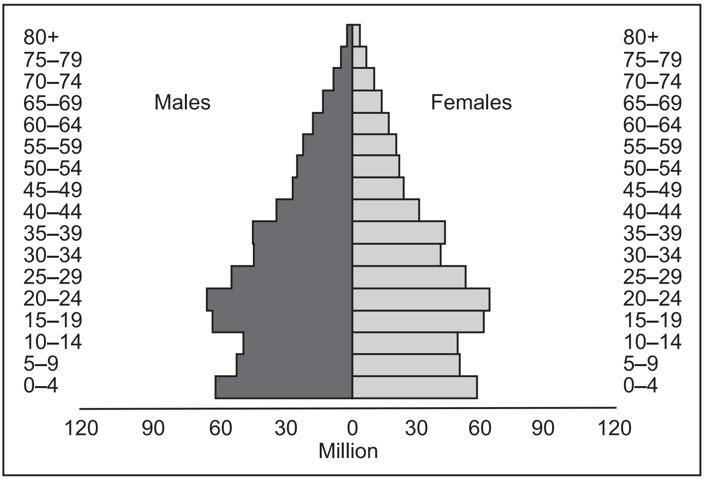
The mounting population pressures in China today are occurring in a world far different from that of a century or two ago. No sparsely settled, habitable areas still exist. No country or group of countries wants to entertain the idea of absorbing 12 million Chinese each year.

Trying to put the brakes on population growth in China has not been easy. The government in Beijing, like those in many other developing countries, waited too long before implementing a meaningful effort to reduce family size. Faced with a trade-off between smaller families in the present or deteriorating living conditions in the future as population pressures mounted, Chinese leaders opted in 1979 for the one couple/one child policy.

This policy, which explicitly reflects the interests of future generations, has run into heavy resistance. One source of difficulty has been a strong preference for male children, a desire so powerful, particularly in rural areas, that it has led to widespread female infanticide. In each annual cohort, males outnumber females until age 64; thereafter, females outnumber males. The conflict between local officials trying to implement this policy and couples intent on having more than one child has led, not surprisingly, to charges of coercion. It illustrates all too well the political conflicts that can develop within a society that is overrunning its human carrying capacity.[33]

Implementing the one-child-family policy has become more difficult in recent years. Job seekers migrating from countryside to city can more easily evade official monitoring of family size. Some families are becoming so affluent that they can readily pay the stiff penalty for having additional children. Moving quickly from a situation of rapid population growth to one of population stability has proved to be politically challenging to say the least.[34]

Nevertheless, it is possible to consider a scenario that would stabilize population size in China well below the 1.66 billion peak projected for 2045. The 1990 population pyramid, which gives the size of various age groups in the population, shows two age groups that are unusually small. (See Figure 8.7.) The first group, those who are 30–34 years of age, was reduced by the famine of 1959–1961. The second, smaller group – those 10–14 years of age – shows the effect of family plan-



Source: See endnote 35.

Figure 8.7 *Age pyramid of China's population, 1990*

ning programmes adopted in the mid-1970s and the echo effect of the smaller numbers born during the famine reaching reproductive age. If China can sustain its one-child-family programme when the people born between 1975 and 1986 reach childbearing age, its population size could stabilize sooner rather than later, and far short of the projected 1.66 billion.[35]

In 1993, the Population Reference Bureau (PRB) pointed out that China had succeeded in lowering its fertility below replacement level – that is, the total number of children per woman was 2 or fewer. This was achieved within two decades of launching family planning programmes.[36]

Carl Haub, senior demographer at PRB, noted that the birth rate was 21.1 per 1000 population in 1990 and that it dropped to 19.7 in 1991 and to 18.2 in 1992. Since then the decline has continued, reaching 17.7 in 1994. This reduced China's population growth rate to 1.1 per cent, roughly the same as that of the US. The drop in China's population growth rate from 2.7 per cent in 1970 to 1.1 per cent in 1994 has played a key role in lowering the global population growth rate during that time from 2.1 per cent to 1.6 per cent.[37]

Recognizing the urgency of stabilizing population size, China's President and Communist Party chief, Jiang Zemin, renewed the call for one couple/one child in March 1995. Concern with the environmental, economic and social effects of continuing population growth in China runs deep. President Jiang pointed out that 'the rapid increase in a big population base has a direct bearing on the problems of food, of jobs, of education, of resource destruction, of environmental protection and an imbalanced ecology.' Increasingly, Chinese leaders are becoming aware of the environmental consequences of the combined effect of population growth and rising affluence that their country is experiencing.[38]

Introduction to Ecoagriculture

J. McNeely and S. Scherr

The Challenge: Agricultural Intensification, Rural Poverty and Biodiversity

Many ecologists fear that the world is poised on the brink of the largest wave of wild species extinctions since the dinosaurs disappeared 65 million years ago. If current trends continue, we could lose or greatly reduce populations of 25 per cent of the world's species by the middle of this century. Since global awareness of this crisis emerged in the late 1970s, conservationists have focused on protecting endangered species and endangered habitats primarily through the establishment of protected areas. Nearly 10 per cent of the Earth's land is now officially protected, and land purchases to create private reserves are expanding such areas. Agricultural production areas, by contrast, have been largely ignored by conservationists. These areas were assumed to have habitat conditions so radically modified from their original state that their potential contribution to biodiversity conservation could only be marginal. Permanent croplands were estimated in the early 1980s to account for only 12 per cent of global land area, so conservation efforts were understandably focused elsewhere (apart from widespread efforts to limit farmland conversion).

Part I [of *Ecoagriculture*] draws on new global data to argue that in this new century food and fibre production – both that produced by agriculture (domesticated crops, livestock, trees and fish) and harvested from natural systems (forests, grasslands and fisheries) has come to be the dominant influence on rural habitats outside the arctic, boreal, high mountain and desert ecoregions. Growing human populations, increasing demand for food and fibre products, and growing concern about rural poverty mean that agricultural output must necessarily expand for at least several more decades until the rate of human population growth begins to stabilize, or even begins to decline (as it already has in some eastern European countries). Adequate growth in supply is by no means assured, especially in areas where productivity is limited by poor soils, difficult climates and insufficient water.

Indeed, the World Bank says that billions of people are at risk of serious food insecurity and deepening poverty.

Future economic development in the poorest and most biodiversity-rich countries will depend heavily on agriculture and natural resource management that continue to enhance productivity and adapt to changing conditions. Agriculture will remain economically and socially important. Even industrialized countries cannot reasonably expect to save biodiversity at the expense of agricultural output and incomes, much less the developing countries of the tropics. Rather, the challenge is to conserve biodiversity while maintaining or increasing agricultural production. Protected areas will remain a critical element of any conservation strategy, but this book [*Ecoagriculture*] stresses that it is essential to focus greater conservation effort on the large areas under agricultural use.

During the 20th century we humans witnessed momentous economic, social and technological changes. New technologies such as automobiles, airplanes, container ships, telephones and computers profoundly affected our way of life, enabling us to escape reliance on local ecosystems and become part of a global economy. Radio, movies and television transformed the way we related to one another and to the world. Public health systems and education became much more widespread, and material wealth – even in the poorest of countries – reached levels inconceivable at the beginning of the century. Our population more than quadrupled, from 1.4 billion in 1900 to more than 6 billion in 2000. As a species, we had a very good century in many ways.

Our 20th-century prosperity was fuelled in part by a constantly growing supply of food, enabling us not only to feed a rapidly growing population, but also to amass food surpluses on a scale never before reached. Based on improved seeds, widespread use of agricultural chemicals, modern farm machinery and better transportation systems, agricultural production soared. In the past decade alone, production of cereal crops increased by 17 per cent, roots and tubers by 13 per cent, meat by 46 per cent and marine fish by 17 per cent (World Resources Institute, 2002). With such impressive gains on so many fronts, why should we worry about the 21st century?

First, although more people are consuming more food than ever before, inequity is increasing as well: some parts of the world suffer from growing overconsumption while others go hungry. The World Bank estimates that some 800 million people remain undernourished, in large part because they cannot access the food that is produced. That number is likely to grow because the world's population increases by 75–85 million people each year. Some experts suggest that in 30 years we will need at least 50–60 per cent more food than we produce now, in order to meet global food demand and enjoy at least a modest degree of greater affluence. If that food is to be accessible to the rural poor, then much of it must be produced where they live, and in ways that increase both their consumption and income. Yet food-producing systems throughout the world are already stressed by eroding soils, declining freshwater reserves, declining fish populations, deforestation, desertification, natural disasters and global climate change. These and various other factors are making it increasingly difficult to maintain, much less increase, food production in many areas of the world.

What is more, the impressive gains for our species have often come at the expense of other species with whom we share our planet. The main victim of our affluence has been wild biodiversity – the non-domesticated portion of our planet's wealth of genes, species and ecosystems. Agricultural production has converted highly diverse natural ecosystems into greatly oversimplified ecosystems, led to pollution of soils and waterways, and hastened the spread of invasive alien species. According to Heywood and Watson (1995), 'over-whelming evidence leads to the conclusion that modern commercial agriculture has had a direct negative impact on biodiversity at all levels: ecosystem, species, and genetic; and on natural and domestic diversity'.

While major investments continue to improve agricultural productivity in centres of surplus commercial production, the needs of the rural poor tend to be ignored. As a result, the poor struggle to survive, managing their resources to meet immediate needs rather than invest in a more secure future. Many of these poor people live in areas remote from modern agricultural development but close to habitats supporting the greatest wild biodiversity. Often they have little choice but to exploit these habitats for survival.

Without urgent action to develop the right kind of agriculture, wild biodiversity will be further threatened. The resulting destruction of natural habitats will deprive both local people and the global community of important benefits such as food, fodder, fuel, construction materials, medicines and genetic resources, as well as services such as watershed protection, clean air and water, protection against floods and storms, soil formation and even human inspiration.

These threats to biodiversity pose a major dilemma for modern society. On the one hand, modern intensive agriculture has made it possible for the expanding human population to eat more food. On the other hand, agriculture is now spreading into the remotest parts of the world, often in destructive forms that further reduce wild biodiversity and undermine the sustainability of the global food production system. At the same time, reducing biodiversity and simplifying ecosystems can undermine local livelihoods by destabilizing ecosystem services. Recent mud slides in several Latin American countries, floods in Bangladesh and droughts in southern Africa are all 'natural' phenomena made into a disaster for local people due at least in part to loss of biodiversity.

This situation has led many in the environmental community and the general public to promote the establishment of protected areas where human use – in particular agricultural use – is supposed to be greatly restricted. While such management measures clearly are needed to preserve many types of wild biodiversity, they face many challenges. Some centres of the greatest or most valued wild biodiversity are being surrounded by areas of intensive agricultural production and high rural population densities. In some areas, large human populations preclude the establishment of extensive reserves, so the protected areas tend to be too small to support viable populations of the species they are designed to protect. In these human-dominated ecosystems, conservation action in isolated protected areas is doomed to fail, unless fundamental changes also take place in the adjacent agricultural landscape. Moreover, some types of wild biodiversity, such as some species of birds and butterflies, actually thrive best in farmed and populated landscapes. Farming is a practice that extends at least 10,000 years back into human history, and many species of plants and animals have evolved in concert with the development of agriculture. Some species of large mammals (especially wild cattle in Asia) may even depend on shifting cultivation (Wharton, 1968).

Aggressive efforts to conserve wild biodiversity have sometimes reduced the livelihood security of rural people, especially the poor in developing countries (Pimbert and Toledo, 1994). But this need not be the case (McNeely, 1999). Rural populations historically have established conservation practices to protect environmental services important to their own food production, water supply and spiritual values (see, for example, Western and Wright, 1994; Singh et al, 2000). Examples show that managing biodiversity through a combination of conservation measures and improved and diversified agricultural systems can increase incomes and household nutrition, reduce livelihood risks and provide collateral benefits such as increased freshwater reserves and fewer mud slides after heavy rains.

Thus new models for biodiversity conservation need to be developed, involving effective links among the fields of farmers, the pastures of ranchers, the managed forests of foresters and the protected areas managed especially for wild biodiversity. Conservation options are available besides just 'locking away' resources on which the poor depend for their survival and assets that low-income countries could use to promote development and national food security. Agricultural landscapes can be designed more creatively to take the needs of local people into account while pursuing biodiversity objectives.

Ecoagriculture

A central challenge of the 21st century, then, is to achieve biodiversity conservation and agricultural production goals at the same time – and, in many cases, in the same space. In this book [*Ecoagriculture*] the management of landscapes for both the production of food and the conservation of ecosystem services, in particular wild biodiversity, is referred to as *ecoagriculture*. For a start, improved natural resource management and technological breakthroughs in agriculture and resource use is essential to enhance our ability to manage biodiversity well. Genetic improvements in the major agricultural crops that feed the world will continue to be essential for maintaining and increasing productivity. But a much wider range of genetic, technological, environmental management and policy innovations must be developed to support wild biodiversity in the world's bread baskets and rice bowls as well as in the extensive areas where food production is more difficult.

Diverse approaches to make agriculture more sustainable, while also more productive, are flowering around the world; many of these reduce the negative effects of farming on wild species and habitats. Such approaches need to be integrated more intentionally with conservation objectives, particularly in biodiversity 'hotspots' (Myers, 1988) and areas where the livelihood of the poor depends on ecosystem rehabilitation. New approaches to agricultural production must be developed that complement natural environments, enhance ecosystem functions and improve rural livelihoods. While trade-offs between agricultural productivity and biodiversity conservation often seem stark, some surprising and exciting opportunities exist for complementarity. Local farmers and institutions, such as universities and agricultural research centres, are leading the way through active experimentation and adaptation of existing knowledge. But more targeted research on ecoagriculture is needed, and such research must be considered a global priority if major advances are to occur. Environmental and agricultural researchers must learn to work closely together to resolve existing conflicts between natural biodiversity and agricultural production in different ecoregions and under different management systems.

This book examines some of the current linkages between wild biodiversity and agriculture. It suggests strategies for improving agriculture while maintaining or enhancing wild biodiversity, assesses dozens of systems where this is already being done and describes how research and policy action can contribute to conserving wild biodiversity. The book is structured in three parts. The first part describes the challenge of reconciling conservation and agricultural goals in areas important for both. The second part discusses the ecoagriculture approach and presents diverse case studies illustrating key strategies. The third part explores how policies, markets and institutions can be reshaped to support ecoagriculture in areas that are hotspots for both biodiversity and food security.

The emphasis here is on tropical regions of the developing world, where increased agricultural productivity is most vital for food security, poverty reduction and sustainable development, and where so much of the world's wild biodiversity is threatened. But the book also highlights lessons learned in developed countries (for example, California Wilderness Coalition, 2002) where these are of wider relevance. While profitable ecoagriculture systems can and must be developed for large-scale commercial farming enterprises that are operating in areas of threatened biodiversity, most examples in this book emphasize strategies for small-scale, low-income farmers involved in commercial or subsistence production.

The biodiversity of domesticated crop and livestock species, and the complex of wild species that directly support agriculture (such as wild pollinators), is also critically important to future prosperity and is also suffering from numerous threats. This book will address how increased agricultural diversity can enhance habitat for wild species, and how strategies to enhance wild biodiversity can build on the beneficial effects of many wild species for agricultural production and sustainability. However, it will not address the topic of genetic diversity of domesticated agricultural species, which has recently begun to receive wide attention from ministries of agriculture and the many agencies that support them (Gemmill, 2002).

As the distinguished British ecologist Norman Myers pointed out, 'It is in the common interest of both agriculture and the natural world that a mutually supportive relationship be developed between them. Production of food need not destroy the wild ecosystems of the world and their wealth of biological diversity. And preservation of wild ecosystems does not pose a threat to humanity feeding itself. In fact, just the opposite is true. Sensible use of nature, which includes substantially increased nature conservation efforts, is essential to feed the planet… Nature equals food. Without wild places, we cannot hope to have food on our tables' (Myers, 1987). And without healthy agriculture, we cannot expect nature to prosper.

Resource-conserving Agriculture Increases Yields in Developing Countries

J. Pretty, A. D. Noble, D. Bossio, J. Dixon, R. E. Hine, F. W. T. Penning de Vries, and J. I. L. Morison

Introduction

What is the best way to increase agricultural productivity in developing countries that still, despite efforts over several decades, have some 800 million people short of food? The question is controversial, with widely varying positions about the types of inputs and technologies likely to be effective (McNeely and Scherr, 2003; Smil, 2000; Tilman et al, 2002; Trewevas, 2002). Great technological progress in the past half century has not been reflected in major reductions in hunger and poverty in developing countries.

However, many novel initiatives have emerged that are demonstrating that agriculture in poor countries can be greatly improved. Here we evaluate how farmers in 286 projects in 57 countries have improved food crop productivity since the early- to mid-1990s, and at the same time increased both water use efficiency and carbon sequestration and reduced pesticide use. These initiatives also offer the prospects of resource conserving agriculture both reducing adverse effects on the environment and contributing to climate change mitigation.

In the past 40 years, per capita world food production has grown by 17 per cent, with average per capita food consumption in 2003 of 2780kcal day^{-1} (FAO, 2005), where a majority of the chronically hungry are small farmers who produce much of what they eat. Yet consumption in 33 poor countries is still less than 2200kcal day^{-1}. Food demand will both grow and shift in the coming decades, as: (i) population growth increases absolute demand for food; (ii) economic growth increases people's purchasing power; (iii) growing urbanization encourages people to adopt new diets; and (iv) climate change threatens both land and water resources.

Increased food supply is a necessary though not sufficient condition for eliminating hunger and poverty. What is important is who produces the food, has access

---

to the technology and knowledge to produce it, and has the purchasing power to acquire it. The great success of industrialized agriculture in recent decades has masked significant negative externalities, with environmental and health problems increasingly well documented and costed, including in Ecuador, China, Germany, the Philippines, the UK and the US (Crissman et al, 1998; Norse et al, 2001; Pingali and Roger, 1995; Pretty et al, 2000; Tegtmeier and Duffy, 2004; Waibel et al, 1999). There are also growing concerns that such systems may not reduce food poverty. Poor farmers need low-cost and readily available technologies and practices to increase local food production and to raise their income. At the same time, land and water degradation is increasingly posing a threat to food security and the livelihoods of rural people who often live on degradation-prone lands (Uphoff, 2002).

The idea of agricultural sustainability centres on food production that makes the best use of nature's goods and services whilst not damaging these assets. Many different terms have come to be used to imply greater sustainability in some agricultural systems over prevailing ones (both pre-industrial and industrialized) (National Research Council, 2000). Agricultural sustainability in all cases, however, emphasizes the potential benefits that arise from making the best use of both good genotypes of crops and animals and their ecological management. Agricultural sustainability does not, therefore, mean ruling out any technologies or practices on ideological grounds (e.g. genetically modified crops, organic practice) – provided they improve productivity for farmers and do not harm the environment (Conway, 1997; National Research Council, 2000; Nuffield Council on Bioethics, 2004; Pretty, 2002; Uphoff, 2002).

In this research, we concentrate on projects that have made use of a variety of packages of resource-conserving technologies and practices. These include:

1 *Integrated Pest Management*, which uses ecosystem resilience and diversity for pest, disease and weed control and seeks only to use pesticides when other options are ineffective.
2 *Integrated nutrient management*, which seeks both to balance the need to fix nitrogen within farm systems with the need to import inorganic and organic sources of nutrients and to reduce nutrient losses through erosion control.
3 *Conservation tillage*, which reduces the amount of tillage, sometime to zero, so that soil can be conserved and available moisture used more efficiently.
4 *Agroforestry,* which incorporates multifunctional trees into agricultural systems and collective management of nearby forest resources.
5 *Aquaculture*, which incorporates fish, shrimps and other aquatic resources into farm systems, such as into irrigated rice fields and fish ponds, and so leads to increases in protein production.
6 *Water harvesting* in dryland areas, which can mean formerly abandoned and degraded lands can be cultivated and additional crops grown on small patches of irrigated land owing to better rain water retention.
7 *Livestock integration* into farming systems, such as dairy cattle and poultry, including using zero-grazing.

Here we show the extent to which recent successful interventions focusing on agricultural sustainability (sometimes called bright spots, see Scherr and Yadav, 1996) have increased total food crop productivity in developing regions. Our questions are:

1 To what extent can farmers increase per hectare and per farm food production by using low-cost and locally-available technologies and inputs?
2 What impacts do such methods have on environmental goods and services (in particular using the water use efficiency, carbon sequestration and pesticide use as proxies to indicate changes in adverse effects on the environment)?

Methodology

We used both questionnaires and published reports of projects to assess adoption of sustainable agriculture and changes over time. As in earlier research (Pretty et al, 2003), data were triangulated from several sources and cross-checked by external reviewers and regional experts. This study involves analysis of projects sampled once in time (n = 218) and those sampled twice over a four-year period to assess temporal changes (n = 68). Not all proposed cases were accepted for the data set, and rejections were based on a strict set of criteria (Pretty et al, 2003). As this was a purposive sample of 'best practice' initiatives, the findings are not representative of all developing country farms.

We used a novel typology of farming systems developed by FAO for the World Bank to classify these projects (Dixon and Gulliver, 2001) into eight broad categories based on the following social, economic and biophysical criteria:

1 the available natural resource base, including water, land, grazing areas and forest; climate and altitude; landscape, including slope; farm size, tenure and organizations; and access to services including markets;
2 the dominant patterns of farm activities and household livelihoods, including field crops, livestock, trees, aquaculture, hunting and gathering, processing and off-farm activities; and the main technologies used, which determine the intensity of production and integration of crops, livestock and other activities.

Table 10.1 contains a summary of the global land area and population located in these eight major farm system categories. On average, these sustain 2.28 people per cultivated hectare of land (range 0.5–5.5). A total of 72 farming subsystems have been identified across the developing regions, some of which comprised similar systems occurring on different continents (e.g. wetland rice systems in East Asia/Pacific and in South Asia). In our study, system categories 2–5 are well-represented,

with 40–95 projects in each. System categories 1, 6 and 8 have 15–20 projects and category 7 has only two.

Extent of agricultural sustainability and impacts on yields

Table 10.2 contains a summary of the location and extent of the 286 agricultural sustainability projects across the eight categories of farming systems in 57 countries. In all, some 12.6 million (M) farmers on 37 M hectares were engaged in transitions towards agricultural sustainability in these 286 projects. This is just over 3 per cent of the total cultivated area shown in Table 10.1. The largest number of farmers was in wetland rice-based systems, mainly in Asia (category 2), and the largest area was in dualistic mixed systems, mainly in southern Latin America (category 6).

We were able to show that agricultural sustainability is spreading to more farmers and hectares. In the 68 randomly re-sampled projects from the original study, there was a 53.6 per cent increase over the four years in the number of farmers and 44.6 per cent in the number of hectares. These resurveyed projects comprised 60 per cent of the farmers and 43.7 per cent of the hectares in the original sample of 208 projects (Pretty et al, 2003). In the earlier study, we reported that 89 projects

Table 10.2 *Summary of adoption and impact of agricultural sustainability technologies and practices on 286 projects in 57 countries*

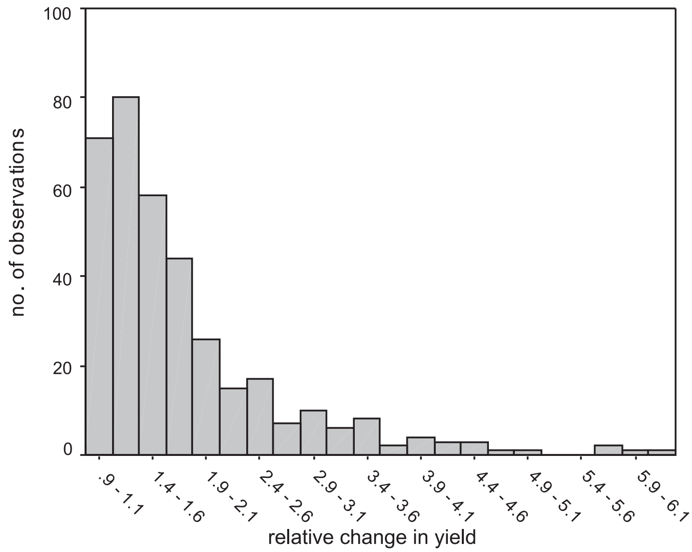
FAO farm system category	*Number of farmers adopting*	*Number of hectares under sustainable agriculture*	*Average % increase in crop yields*
1. Smallholder irrigated	177,287	357,940	129.8 (±21.5)
2. Wetland rice	8,711,236	7,007,564	22.3 (±2.8)
3. Smallholder rainfed humid	1,704,958	1,081,071	102.2 (±9.0)
4. Smallholder rainfed highland	401,699	725,535	107.3 (±14.7)
5. Smallholder rainfed dry/cold	604,804	737,896	99.2 (±12.5)
6. Dualistic mixed	537,311	26,846,750	76.5 (±12.6)
7. Coastal artisanal	220,000	160,000	62.0 (±20.0)
8. Urban-based and kitchen garden	207,479	36,147	146.0 (±32.9)
All projects	12,564,774	36,952,903	79.2 (±4.5)

Notes: Yield data from 360 crop project combinations; reported as % increase (thus a 100% increase is a doubling of yields). Standard errors in brackets.

for which there was reliable yield data showed increases in per hectare food production.

For the 360 reliable yield comparisons from 198 projects that we now have, the mean relative increase was 79 per cent across the very wide variety of systems and crop types. However, there was a wide spread in results (Figure 10.1). While 25 per cent of projects reported relative yields > 2.0 (i.e. 100 per cent increase), half of all the projects had yield increases of between 18 per cent and 100 per cent. The geometric mean is a better indicator of the average for such data with a positive skew, but this still shows a 64 per cent increase in yield. However, the average hides large and statistically significant differences between the main crops (Figures 10.2 and 10.3). In nearly all cases there was an increase in yield with the project. Only in rice were there three reports where yields decreased and the increase in rice was the lowest (mean = 1.35), although it constituted a third of all the crop data. Cotton showed a similarly small mean yield increase.

The mean (2.84) and spread was largest in cassava and sweet potato crops, although the sample is small. Soybean and groundnut showed mean increases of about 50 per cent. Maize, millet and sorghum, potatoes and the other legumes group (beans, pigeon peas, cowpea, chickpea) all showed mean yield increases of > 100 per cent, significantly higher than for cotton, rice and groundnut ($p < 0.05$). For most of the main field crops that are well represented in the survey, those with



Notes: $n = 360$, mean = 1.79, s.d. 0.91, median = 1.50, geometric mean = 1.64.

Figure 10.3 *Mean changes in crop yield after or with project, compared with before or without project*

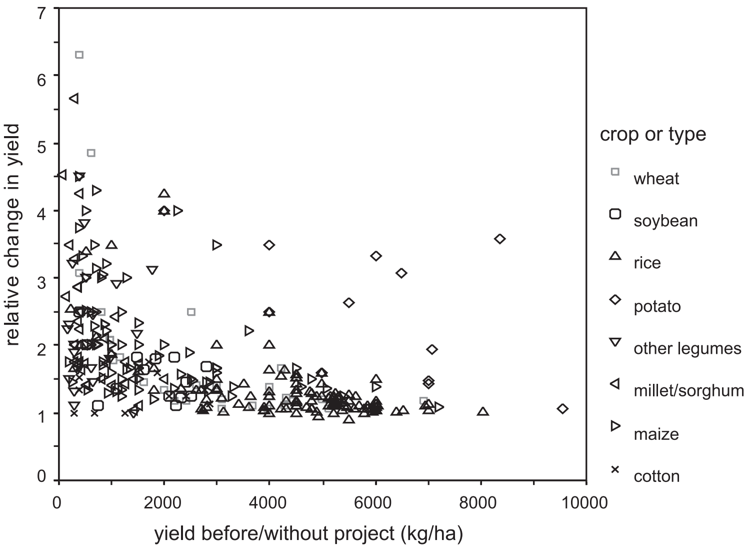
low yields before intervention often showed larger relative improvements, either because of growth limiting environments, or perhaps reduced investment in developing these crops, although potato showed large increases across the range (Figure 10.4).

Though many technologies and practices were used in these projects, three types of technical improvement are likely to have played substantial roles in food production increases:

1 more efficient water use in both dryland and irrigated farming;
2 improvements in organic matter accumulation in soils and carbon sequestration;
3 pest, weed and disease control emphasizing in-field biodiversity and reduced pesticide (insecticide, herbicide and fungicide) use.

Impacts on farm water use efficiency

Widespread appreciation of the 'global water crisis' recognizes that scarcity of clean water is affecting food production and conservation of ecosystems. By 2025 it is predicted that most developing countries will face either physical or economic water scarcity (International Water Management Institute, 2000). Water diverted from rivers increased six-fold between 1900 and 1995 (Shiklomanov, 1999), far



Note: Only field crops with n > 9 shown.

Figure 10.4 *Relationship between relative changes in crop yield after (or with project) to yield before or (without project)*

outpacing population growth. Increasing demand for fresh water now threatens the integrity of many aquatic ecosystems and their associated environmental services (Costanza et al, 1997). As agriculture accounts for 70 per cent of current water withdrawals from rivers, so improving the productivity of water use in agriculture is a growing challenge.

The potential for increasing food production while maintaining water-related ecosystem services rests on the capacity to increase water productivity (WP), i.e. by realizing more kg of food per unit of water. Sustainable agricultural practices may do this by: (i) removing limitations on productivity by enhancing soil fertility; (ii) reducing soil evaporation through conservation tillage; (iii) using more water efficient varieties; (iv) reducing water losses to unrecoverable sinks; (v) boosting productivity by supplemental irrigation in rainfed systems; and (vi) inducing microclimatic changes to reduce crop water requirements (Kijne et al, 2003). We calculated changes in WP for field crops in 144 projects from the data set (Table 10.3) based on reported crop yields and average potential evapotranspiration (ETp), for each project location during the relevant growing season. Actual evapotranspiration (ETa) was assumed to equal 80 per cent of ETp, and ETa to remain a constant at different levels of productivity.

WP gains were high in rainfed systems and moderate in irrigated systems, and were in agreement with other studies reporting ranges of WP (Kijne et al, 2003). The very large increase for the vegetables and fruits is probably an overestimate as

Table 10.3 *Summary of changes in water productivity by major crop type arising from adoption of sustainable agricultural technologies and practices in 144 projects*

Crops	*Water productivity before intervention (kg food m^{-3} water ETa)*	*Water productivity after intervention (kg food m^{-3} water ETa)*	*Water productivity gain (kg food m^{-3} water ETa)*	*% Increase in WP*
Irrigated				
Rice (*n* = 18)	1.03 (±0.22)	1.19 (±0.12)	0.16 (±0.04)	15.5%
Cotton (*n* = 8)	0.17 (±0.04)	0.22 (±0.05)	0.05 (±0.02)	29.4%
Rainfed				
Cereals (*n* = 80)	0.47 (±0.06)	0.80 (±0.09)	0.33 (±0.05)	70.2%
Legumes (*n* = 19)	0.43 (±0.07)	0.87 (±0.16)	0.44 (±0.11)	102.3%
Roots and tubers (*n* = 14)	2.79 (±0.73)	5.79 (±1.08)	3.00 (±0.65)	107.5%
Urban and kitchen gardens				
Vegetables and fruits (*n* = 5)	0.83 (±0.29)	2.96 (±0.97)	2.13 (±0.71)	256.6%

Note: Standard errors in brackets.

we did not adjust ETp for new crops or lengthened cropping periods. Variability was high due to the wide variety of practices represented in the data set, but do indicate that gains in WP are possible through the adoption of sustainable farming technologies in a variety of crops and farm systems. Our results, and others (Agarwal and Narain, 1997; Rockström and Falkenmark, 2000), demonstrate that the greatest opportunity for improvement in water productivity is in rainfed agriculture. Better farm management, including supplemental irrigation and fertility management, can significantly reduce uncertainty and thus avoid chronic low productivity and crop failure that are characteristic of many rainfed systems.

Impacts on carbon sequestration

The 1997 Kyoto Protocol to the UN Framework Convention on Climate Change established an international policy context for the reduction of carbon emissions and increases in carbon sinks in order to address the global challenge of anthropogenic interference with the climate system. It is clear that both emission reductions and sink growth will be necessary for the mitigation of current climate change trends (IPCC, 2001; Lal et al, 2004; Swingland, 2003). Carbon sequestration is defined as the capture and secure storage of carbon that would otherwise be emitted to or remain in the atmosphere (Watson et al, 2000).

One of the actions farmers can take is to increase carbon sinks in soil organic matter and above-ground biomass. We calculated the potential annual contributions

Table 10.4 *Summary of potential carbon sequestered in soils and above-ground biomass in the 286 projects*

FAO farm system category	*Carbon sequestered per hectare ($t\ C\ ha^{-1}\ y^{-1}$)*	*Total carbon sequestered ($Mt\ C\ y^{-1}$)*	*Carbon sequestered per household ($t\ C\ y^{-1}$)*
1. Smallholder irrigated	0.15 (±0.012)	0.011	0.06
2. Wetland rice	0.34 (±0.035)	2.530	0.29
3. Smallholder rainfed humid	0.46 (±0.034)	0.340	0.20
4. Smallholder rainfed highland	0.36 (±0.022)	0.230	0.56
5. Smallholder rainfed dry/cold	0.26 (±0.035)	0.200	0.32
6. Dualistic mixed	0.32 (±0.023)	8.030	14.95
7. Coastal artisanal	0.20 (±0.001)	0.032	0.15
8. Urban-based and kitchen garden	0.24 (±0.061)	0.015	0.07
Total	0.35 (±0.016)	11.380	0.91

Note: Standard errors in brackets.

being made in these 286 projects to carbon sink increases in soils and trees, using established carbon audit methods (Pretty et al, 2002) (Table 10.4). As the focus is on what sustainable methods can do to increase quantities of soil and above-ground carbon, we did not take account existing stocks of carbon. Soil carbon sequestration is corrected for climate, as rates are higher in humid compared with dry zones, and generally higher in temperate rather than tropical areas (Lal et al, 2004; Watson et al, 2000).

These projects were potentially sequestering 11.4 Mt C y^{-1} on 37 M ha. If scaled up, assuming that 25 per cent of the areas under the different farming system categories globally (Table 10.1) adopted these same sustainability initiatives, this would result in sequestration of 100 (±4) Mt C y^{-1}. The average gain was 0.35 (±0.016) t C ha^{-1} y^{-1}, and an average gain per household of 0.91 t C y^{-1}. The per hectare gains vary from 0.15 (±0.012) t C ha^{-1} y^{-1} for smallholder irrigated systems (category 1) to 0.46 (±0.034) t C ha^{-1} y^{-1} for category 3 systems. For most systems, per households gains were in the range 0.05–0.5 t C y^{-1}, with the much larger farms of southern Latin America using zero-tillage achieving the most at 14.9 t C y^{-1}. Such gains in carbon may offer new opportunities for income generation under carbon trading schemes.

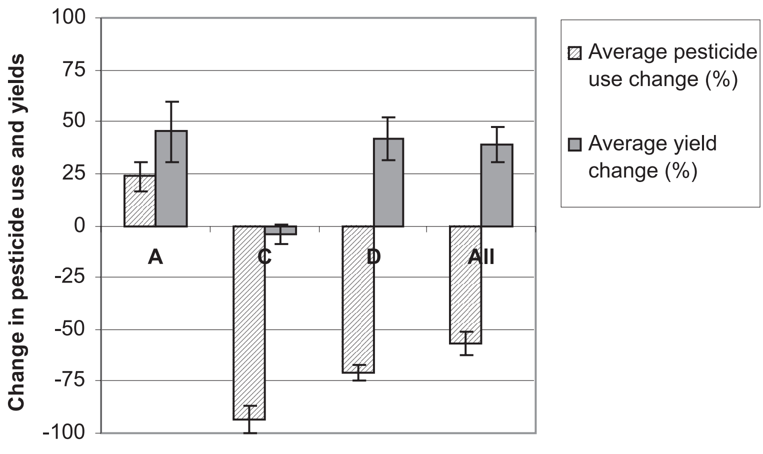
Impacts on pesticide use

Integrated Pest Management (IPM) programmes are beginning to show how pesticide use can be reduced and modified without yield penalties in a variety of farm systems, such as in irrigated rice in Asia (Eveleens, 2004) and rainfed maize in Africa (Khan et al, 1997). In principle, there are four possible trajectories an agricultural system can take if IPM is being introduced:

1 both pesticide use and yields increase (A);
2 pesticide use increases but yields decline (B);
3 both pesticide use and yields fall (C);
4 pesticide use declines, but yields increase (D).

The conventional wisdom is that pesticide use and yields are positively correlated, and so only trajectories moving into A and C are likely (Knutson et al, 1990; Schmitz, 2001). A change into sector B would be against economic rationale, as farmers' profits would invariably fall and behaviour change. A shift into sector D would indicate that current pesticide use has negative yield effects. This could be possible with an excessive use of herbicides or when pesticides cause outbreaks of secondary pests (Kenmore et al, 1984). We analysed the 62 IPM initiatives in 21 developing countries in the data set (Figure 10.5). The evidence on pesticide use is derived from data on both the number of sprays per hectare and the amount of active ingredient per hectare. There is only one case in sector B reported in recent literature (Feder et al, 2004), and so this was not included.

Sector A contains ten projects where pesticide use increased. These are mainly in zero-tillage and conservation agriculture systems, where reduced tillage creates benefits for soil health and reduces off-site pollution and flooding costs. These



Notes: A: $n = 10$; C: $n = 5$; D: $n = 47$.

Figure 10.5 *Changes in pesticide use and yields in 62 projects* systems usually require increased use of herbicides for weed control (de Freitas, 1999), though there are examples of organic zero-tillage systems (Petersen et al, 2000). The five cases in sector C show a 4.2 per cent (±5.0) decline in yields with a 93.3 per cent (±6.7) fall in pesticide use. Most cases, however, are in category D where pesticide use declined by 70.8 per cent (±3.9) and yields increased by 41.6 per cent (±10.5). While pesticide reduction is to be expected, as farmers substitute pesticides with information, the cause of yield increases induced by IPM are complex. It is likely that farmers who receive good quality field training will not only improve their pest management skills but also become more efficient in other agronomic and ecological management practices. They are also likely to invest cash saved from pesticides in other inputs such as higher quality seeds and fertilizers. This analysis indicates a considerable potential for avoiding environmental costs.

Discussion

It is uncertain whether progress towards agricultural sustainability, delivering benefits at the scale occurring in these projects, will result in enough food to meet the future food needs in developing countries after continued population growth, urbanization and the dietary transition to meat-rich diets (Delgado et al, 1999). Even the substantial increases reported here may not be enough. However, more widespread adoption of these resource conserving technologies, combined with other innovations in crop and livestock genotypes, would contribute to increased agricultural productivity (Nuffield Council on Bioethics, 2004; Trewevas, 2002), particularly as evidence indicates that productivity can grow in many farming systems as social and human capital assets also grow (Pretty, 2003). Our findings also show that poor households benefit substantially.

But improving agricultural sustainability will not alone solve all food poverty problems. The challenge is to find ways to improve all farmers' access to productive technologies and practices that are also resource conserving. The critical priority is now international, national and local policy and institutional reforms (Dasgupta, 1998) designed to benefit both food security and income growth at national and household levels, whilst improving the supply of critical technologies that improve the supply of environmental goods and services.

Acknowledgements

We are grateful to all project staff and scientists who made data available on projects, to earlier comments and suggestions from researchers involved in the IWMI Bright Spots research programme, to Noel Aloysius for input for some of the research, to David Tilman for comments on an earlier manuscript, and to two referees for their helpful comments. The research was funded by the UK Department for International Development. The views expressed in this paper are those of the authors and do not necessarily reflect the policies of their organizations.

Supporting information

See Dixon and Gulliver (2001) for full details of the classification system developed by FAO. This separates farming systems into eight types (irrigated; wetland rice based; smallholder rainfed humid; smallholder rainfed highland; smallholder rainfed dry/cold; dualistic; coastal artisanal fishing; urban-based) for six regions of the world (sub-Saharan Africa; Middle East and North Africa; Europe and Central Asia; South Asia; East Asia and Pacific; Latin America and Caribbean).

Part III

Diet and Health

11

Whole Diets

E. Balfour

In the Introduction to his book, *The Wheel of Health*,[1] Dr Wrench makes this thought-provoking statement: 'After debating the question – Why disease? Why not health? – again and again with my fellow students, I slowly, before I qualified, came to a further question – Why was it that as students we were always presented with sick or convalescent people for our teaching and never with the ultra healthy? Why were we only taught disease: why was it presumed that we knew all about health in its fullness? The teaching was wholly one-sided. Moreover, the basis of our teaching upon disease was pathology, namely, the appearance of that which is dead from disease.'

This view, that the professional attitude to sickness is one-sided is shared by the compilers of the PEP Report (1936) on the British Health Services. The authors express it as follows:

> Health means more than not being ill. A new attitude is needed, involving not so much a departure from the old as a more thorough grasp of the different elements in health policy. Many people are at any given moment suffering from defects, injuries or sickness so pronounced as to make them unable to carry on ordinary occupations and leisure activities. These are the 'cases' with which a large part of the organized health services mainly deal. But in addition there are far larger numbers of people suffering temporarily or permanently from less acute defects, injuries, or inadequacies, which are not sufficient to unfit them for work or play, and may not even be noticed at all, but nevertheless suffice to place them in an unnecessarily weak position for creating and maintaining good physique, energy, happiness, or resistance to disease... No contemporary health policy can be considered adequate which does not deal with the second group as well as the first...
>
> While efforts at effecting the cure of diseases cannot be relaxed, efforts at prevention of ill health can and must be increased. The aspect of raising standards of nutrition and of fitness should be given much prominence. Health must come first: the mere state of not being ill must be recognized as an unacceptable substitute, too often tolerated or even regarded as normal. We must, moreover, face the fact that while immense study has been lavished on disease no one has intensively studied and analysed health,[2] and our

Reprinted from Balfour E. 1943. Whole diets, in Balfour E. *The Living Soil*, Faber and Faber, London. Chapter 7, pp161–179.

> ignorance of the subject is still so deep that we can hardly claim scientifically to know what health is.

The theory which I have endeavoured to expound in this book [*The Living Soil*] is that the only true conception of health is one of wholeness, dependent upon both the continuity and the completeness of the cycle of life. I shall make no attempt to discuss the philosophical aspect of this conception, I am concerned only with presenting certain evidence suggesting that it is biologically sound. For the sake of clarity in this presentation, the argument has been divided into two parts. The first states that the determining factor in health is food, and the second suggests that the health-giving property of food is dependent on the way it is grown, prepared and consumed.

There is always an inherent danger in making arbitrary divisions where no true division exists, but in the present case this could hardly be avoided. The risk of failing to see the wood for the trees must sometimes be taken in order to discover how large a number of trees go to make a wood. In the previous chapters [of *The Living Soil*] – to pursue the same analogy – I have invited you to examine some of the trees. In this chapter I want you to take a look at the wood as a whole. This, research has, so far, largely failed to do. Research workers in chemistry, biology, mycology, botany, veterinary science and medicine, have for too long been working in watertight compartments, each busily dissecting his own tree, until in the process the wood has become so sadly dismembered it is small wonder that we sometimes cease to be aware of its existence.

It may be objected that I have followed their example of fragmentation in laying so much stress on the role of the fungus in nutrition. In so far as this accusation is well founded, my defence is that this is the link in the life cycle which is most frequently omitted, but which is at the same time the easiest to restore. In emphasizing its importance, however, I have never intended to suggest that it forms other than a part, however important in itself, of the complete cycle of nutrition and health which is wholeness.

McCarrison in the Cantor Lectures states: 'The diet of the Sikhs is only health-promoting so long as it is consumed in its entirety', and as Dr Wrench points out, with their whole diet these people 'have preserved the wholeness of their health, a thing which we have failed to do'.

> In the writings of the scientific experts on nutrition, there are very numerous part-diet experiments based on synthetic or specially made-up diets, omitting or cutting down the quantity of one or more of the factors which compose a diet. One scientist will cut down the quantity of protein given and watch the effect of this upon animals; another will cut down the fats and note the resulting sicknesses; another will give vegetable or irradiated vegetable fats in places of customary animal fats; another will give a diet in which vitamin A is defective, B is defective, C is defective, and so on.
>
> The experiments are skilfully devised and carried out with consumate technique. They lead to a mass of knowledge about proteins as things in themselves; fats as things

> in themselves; vitamins as things in themselves; but whether these can be things in themselves and are not really relative to a host of other conditions in nutrition is as yet scarcely considered...
>
> Our health or wholeness has fragmented no less than our diet. A swarm of specialists have with the invention of science settled on the fragments to study them. A great deal is found out about each several disease; there is a huge, unmanageable accumulation of knowledge, and this and that disease is checked or overcome. But our wholeness has not been restored to us. On the contrary, it is fragmented into a great number of diseases and still more ailments. We have lost wholeness, and we have got in its place its fragmentation with a multiplexity of methods, officially blessed and otherwise, dealing with the fragments in their severally.

This fragmentation has resulted, among other things, in a host of contradictory views among dietitians, each one of the different diets advocated possessing a company of followers ready to argue its exclusive merits with almost religious fervour. Thus you have the vegetarian; the fruitarian; those who never eat proteins and starch at the same meal; and those who stew all their foods together in the same pot; those that say you must drink before meals; others that believe in drinking after meals; those that drink between meals, and besides all these, and many more, there is the vast majority that eat what they want when they want it (or can get it) and drink when they are thirsty. This majority is given to labelling all the others as faddists, and indeed there does not seem to be a very noticeable difference in health between any of these groups. No wonder then, that the average person is apt to be a little sceptical when he is told that health depends on diet.

What then should be the reply to the would-be seeker after health who asks: 'What shall I eat that I may be whole?'

For an answer let us go to those people from whom Dr Wrench, in his student days, felt instinctively that such knowledge should be sought, namely the ultra-healthy. Not the occasional individual of whom one says that he is 'abnormally healthy' (a revealing adverb) but to whole groups of people to whom a state of full health is normal.

Five such groups exist, or have existed, about which a good deal of statistical data is available. We will examine these in turn, noting how they live and what they eat, and see if we can discover among them a common factor of which it permissible to say – here lies the secret of health.

We will take first the people of Hunza, a small native state in the extreme northernmost part of India attached to the Gilgit Agency. The origin of these people is somewhat of a mystery. Both in physical characteristics and language they differ from their neighbours, and indeed from all the other peoples of the Indian subcontinent. Only one thing seems certain, that they have inhabited their valley since the extremely distant past. The massive stone walls, the building of which must have preceded their admirable terraced agriculture, have a parallel only in the masonry left by the Peruvian civilization which preceded the Inca conquest.

The Hunza valley is a gorge running east and west cleft in a towering mountain range. It is arid in summer and bitterly cold in winter, but owing to the system of irrigation, it is extremely fertile and an immense variety of fruits and vegetables are cultivated by these industrious people.

Something of their superb health and stamina has already been indicated in Chapter 2 [of *The Living Soil*]. All travellers passing through their valley speak of their outstanding physique, courage and good humour. McCarrison, who for some time was Medical Officer to the Gilgit Agency, has said of them:

> These people are unsurpassed by any Indian race in perfection of physique. They are long lived, vigorous in youth and age, capable of great endurance and enjoy a remarkable freedom from disease in general.
>
> During the period of my association with these people I never saw a case of asthenic dyspepsia, of gastric or duodenal ulcer, of appendicitis, of mucous colitis, of cancer...
>
> Among these people the 'abdomen over-sensitive' to nerve impressions, to fatigue, anxiety, or cold was unknown. The consciousness of the existence of this part of their anatomy was, as a rule, related solely to the feeling of hunger. Indeed, their buoyant abdominal health has, since my return to the West, provided a remarkable contrast with the dyspeptic and colonic lamentations of our highly civilized communities.

They are admirable cultivators:

> far famed as such and 'conspicuously ahead of all their neighbours in brain and sinew' stated Shomberg. Their big irrigation conduit, the Berber, is 'famous everywhere in Central Asia...'
>
> Amongst the peoples of the Agency not only are they 'as tillers of the soil quite in a class apart, they alone – and this always strikes me as truly remarkable – are good craftsmen.' As carpenters and masons, as gunsmiths, ironworkers, or even as goldsmiths; as engineers for roads, bridges or canals, the Hunza men are outstanding.

The Hunza are favoured in their fertile valley, but their perfect health cannot be put down to the locality in which they live, for next door to them is another, and equally fertile, valley, also running east and west and separated from Hunza only by a 20,000-foot mountain wall. In this valley live the Ishkomanis. These people, 'though living under apparently like conditions to their neighbours, were poor, undersized, undernourished creatures. There was plenty of land and water, but the Ishkomanis were too indolent to cultivate it with thoroughness; and the possibility of bad harvests was not enough to overcome their sloth… "They had no masons or carpenters or craftsmen in their country. Many of them showed signs of disease."'

We can thus rule out climate as the secret of the Hunza health. Now, let us look at their mode of life and their diet. For ten months of the year they can be said to live in the open air, for men, women and children work in the fields. They remain mainly indoors during the period of severe winter storms, but their houses are better, and better ventilated than those of their neighbours, their sanitation is also better and follows the 'immemorial custom of the Far East'. Unusual care is also taken to protect their drinking water by storing it in separate covered cisterns.

Their diet is a very varied one. It consists of

> wheat, barley, buckwheat, and small grains; leafy green vegetables; potatoes (introduced half a century ago), other root vegetables; peas and beans, gram or chick pea, and other pulses; fresh milk and buttermilk or lassi; clarified butter and cheese; fruit, chiefly apricots and mulberries, fresh and sun-dried; meat on rare occasions; and sometimes wine made from grapes. Their children are breast fed up to three years, it being considered unjust to the living child for its lactation to be interrupted by a maternal pregnancy.
>
> The Hunza do not take tea, rice, sugar or eggs. Chickens in a confined area destroy crops and are not kept.

Except for the wider range of small grains and the very occasional meat, this closely resembles any European lacto-vegetarian diet, and, at first sight, seems to support the view so widely held by nutrition experts, McCarrison among them, that of all diets the lacto-vegetarian is the healthiest. That it is a good diet is incontestable; it will, however, presently be shown that there are other peoples whose health and stamina is equal to that of the Hunza whose diet is the very opposite of theirs.

The Hunza foods then are not unlike our own, but there are important differences in the normal methods of preparation and cooking. Both we and the Hunza are great bread-eaters, and both prefer wheat bread, but the Hunza wheat is eaten freshly ground, and the unleavened bread made with it invariably contains the whole of the grain, with its vital germ and its protective skin, both of which are removed in the process of milling white flour.

Dr Wrench, writing on the properties of skin in general, points out that skin does not protect only in a mechanical way as a mere covering, but in a living way. All skins 'can regrow themselves if injured, and beneath and within them they store substances upon which they can call to strengthen their efforts'. The value of bran, the skin of wheat, is well known to all stock feeders. All carnivorous animals relish the skins of their prey. The Greenlanders, Wrench points out, eat the skin of the narwhal: 'The Chinese and other peoples also eat the skins of animals and birds. Everything living has a skin of some sort to protect it. It protects it by its extra toughness, but also if microbes and other minute enemies do attack, it is there on the frontier that the battle is waged. In and near the skin are marshalled the protective forces. Any creature that eats the skin of vegetable, fruit, or animal, also eats these protective materials marshalled on the frontier, and may benefit in its own protection thereby. Whether such a pretty hypothesis is true or not, there are suggestions that skins possess a peculiar value… The skin and adjacent part of the potato is the best part, as the Irish know. So also is it the case with the carrot, and, it is said, with young marrows, cucumbers, gherkins, artichokes, radishes, and celery. There is, therefore, a little evidence for the hypothesis.'

A fondness for skin is an outstanding feature of the Hunza, they do not peel their vegetables, or wash and soak them to the extent we do. Vegetables play a great part in their diet and are very commonly eaten raw. 'They are fond of raw green corn, young leaves, carrots, turnips, and, as it were to exaggerate their veneration for freshness, they sprout their pulses and eat them and their first green. This eating of sprouting pulse or gram is widespread in northern India, and undoubtedly within it there is a health which there is not in the pulse itself.'

Fuel in Hunza is scarce, and when they do cook their vegetables they are boiled in covered pots as is the usual habit in this country.

'But the process is more comparable to our way of steaming and cooking in their own juice. Very little water is added. When this has been used up more is added. The water in which the vegetables are cooked is drunk either with the vegetables or later. The point is that it is part of the food. It is not thrown away.'

This taking of vegetable water is obviously sensible, for many of the valuable mineral salts which vegetables contain pass into the water in which they are cooked, particularly if the vegetables are peeled before cooking. 'There is abundant evidence from the scientists of the loss that occurs through the throwing away of vegetable water of phosphorus, calcium, iron, iodine, sulphur, etc. Quite a considerable proportion of the pharmacopoeia seems to have arisen owing to this waste. Quite a considerable number of the doctors' prescriptions and patent medicines may be due to the need to replace the salts of the food in those who suffer from this loss. The similarity of the medicines and the lost salts is too close for one not to be profoundly suspicious that the methods of cooking cause or contribute to the subsequent need of the medicines.'

The Hunza drink milk in considerable quantity, they drink it whole and they boil the fat from it to form clarified butter or ghee, which they spread on their bread and also use for cooking. They drink the buttermilk which remains, and both this and their whole milk they preserve in hot weather by souring. Meat is a 'rare pleasure', most of their livestock being dairy animals. They rarely eat meat more than once in ten days, and often only about once a month. When they do, they eat all that is edible in the carcass and stew it together with their vegetables and pounded wheat. But ranking above all the foregoing in the Hunza diet is fruit. '"The Hunza are great fruit eaters, especially of apricots and mulberries. They use apricots and mulberries in both the fresh and dry state, drying sufficient of their rich harvest of them for use throughout the autumn and winter months." (McCarrison.) They eat the fruit fresh in season, cracking the stones and eating the kernels as well. Otherwise they take them, particularly sun-dried apricots, and eat them as they are, or rub them in water to form a thick liquid called *chamus*. Dried mulberries they put into cakes as we do sultanas. They do not cook their fruits. "Fruit is really the Hunza staple. It is eaten with bread, far more so than vegetables, as it is more abundant."' (Schomberg.) '"Even the animals," said Durand, "take the fruit diet, and you see donkeys, cows and goats eating the fallen mulberries. The very dogs feed on them, and our fox-terriers took to the fruit regimen most kindly and became quite connoisseurs."' They ferment some of their fruit juices and on festive occasions drink their own home-made wine.

So far the main differences between the Hunza diet and our own seems to be that the Hunza foods are all natural foods, they are eaten fresher than ours, and they are consumed whole, but there is one more difference, the most fundamental of all, and this lies in the way in which these foods are grown.

In their system of agriculture which has been continued 'century after century' the chief factors in their plant food have been two.

> Firstly, there is the continuous slight renewal of the soil by a sprinkling of the black glacier-ground sand, which is brought to the fields by the aqueducts.
>
> Secondly, there is the direct preparation by man of food for the plants, given in the form of manure.
>
> The Hunza, in their manuring, use everything that they can return to the soil. They carefully collect the cattle manure and store it in the byres. They collect all vegetable parts and pieces that will not serve as food to either man or beast, including such fallen leaves as the cattle will not eat, and mix them with the dung and urine in the byres. They use the human sewage after keeping it for six months. They take silt from special recesses built in their irrigating channels. They collect the ashes of their fires. All these they mix together and make into a compost. They also spread alkaline earth from the hills on their vegetable fields on days when the fields are watered.

O. F. Cook of the Bureau of Plant Industry of the US Department of Agriculture has written: 'Agriculture is not a lost art, but it must be reckoned as one of those which reached a remarkable development in the remote past and afterwards declined.' As an example he cites the system of the ancient Peruvians which enabled them to support large populations in places 'where modern farmers would be helpless'.[3]

Travellers who have visited both Peru and the North-West Indian Provinces have been struck by the resemblance between the stone aqueducts and mammoth walls that support the terraced fields of both areas. Describing those of Hunza the late Lord Conway wrote:

> The path that leads up to Baltit[4] is bordered on either side by a wall of dry cyclopean masonry the undressed component parts of which are very large and excellently fitted together … a monumental piece of simple engineering … the valley between the cliffs and the edge of the river's gorge is covered with terraced fields… The cultivated area of the oasis is some five square miles in extent. When it is remembered that the individual fields average as many as twenty to the acre, it will be seen what a stupendous mass of work was involved in the building of these walls and the collection of earth to fill them. The walls have every appearance of great antiquity, and alone suffice to prove the long existence in this remote valley of an organized and industrious community…
>
> To build these fields was the smaller part of the difficulties that husbandmen had to face in Hunza. The fields also had to be irrigated. For this purpose there was but one perennial supply of water – the torrent from the Ultar glacier. The spout of that glacier, as has been stated, lies deep in a rock-bound gorge, whose sides are for a space perpendicular cliffs. The torrent had to be tapped, and a canal of sufficient volume to irrigate

> so large an area had to be carried across the face of one of these precipices. The Alps contain no *Wasserleitung* which for volume and boldness of position can be compared to the Hunza canal. It is a wonderful work for such toolless people as the Hunzakats to have accomplished, and it must have been done many centuries ago and maintained ever since, for it is the life-blood of the valley.

Thus it can be seen that the Hunza appear to form a direct link between the present day and that 'remote past' in which agriculture reached such a 'remarkable development'. They are a people perhaps as ancient as the Incas, but who, unlike the Incas, have survived, and in their survival have preserved their ancient lore, and in the preservation of that lore have preserved the wholeness of their health and that of their crops and livestock, which Dr Wrench tells us is on a par with their own.

The blight which Western civilization usually casts on such people, has so far escaped them. Whether it will continue to do so is another matter. Since they have come under British suzerainty their population has increased from about six thousand to fourteen thousand, and this has resulted in a shortage of food in the preharvest period:

> Colonel D. L. Lorimer, who was Political Agent at Gilgit, 1920–4, and revisited the Hunza and lived amongst them at Alibad, 1933–4, four miles from the capital, Baltit, told me that not only did they seem smaller to him at his second visit, but that the children appeared under-nourished for the weeks preceding the first summer harvests half-way through June; and, moreover, that the children suffered at that time of the year from impetigo, or sores of the skin, all of which vanished when the more abundant food came.

A sign, incidentally, that it is not by virtue of their race, or habitat, or housing, that they are normally immune from bodily ailments.

We will now go from Latitude 37 to the northern and Arctic regions: from the lacto-vegetarian diet of the Hunza to the carcass diet of the islanders of Faroe, Iceland and Greenland. Early records of these peoples show them to have been every whit as healthy as the Hunza, yet these people are, or were, almost entirely carnivorous.

> These Danish possessions are three isolated lands from which no Western civilized person would expect to glean wisdom. But, as we have already seen in the case of food and health, isolation locks up the most valuable secrets. The peoples of these three lands, living either near or actually within the Arctic Circle, offer in three degrees, from Faroe to Greenland, an increasingly animal-fish-bird diet. It must not be called a meat diet; that is inaccurate as will be seen. It was largely a diet from the sea, and with the great health of the sea, a 'soil' outside the realms of terrestrial man.
>
> The diet of the Faroe Islanders, when they were more isolated than now, was given in a book published by the Edinburgh Cabinet Library in 1840. It was mainly a whole-carcass diet of animal, bird and fish. The islanders ate not merely meat, but everything

that could be eaten. There was no such thing as offal. They also made the carcasses gamey by hanging for weeks and even months. In addition to their whole-carcass food they had barley meal, unleavened barley bread, a few vegetables such as cabbages, parsnips and carrots.

They drank milk, beer, and, on festive occasions, brandy. But the main food was animal, bird and fish.

The islanders numbered a few thousands, were of the same origin as the Icelanders, and were, 'in general, remarkably intelligent. They are extremely healthy, and live to a great age, and an old man of ninety-three years lately rowed the governor's boat nearly ten miles.' One danger they incurred was an epidemic catarrhal fever, such as we call influenza, which 'prevails after the arrival of the ships from Denmark in the spring', after the winter's scarcity. It spreads rapidly and was sometimes fatal. Otherwise, 'but few diseases are prevalent amongst them'.

The inhabitants of Iceland offer a similar and even more interesting picture of carcass diet. McCollum and Simmonds, in *The Newer Knowledge of Nutrition* (1929) summarize the chief facts. 'This island was settled in the 9th century by colonists from Ireland and Scandinavia, who took with them cattle, sheep and horses. Their diet was practically carnivorous in nature for several hundred years. Martin Behaim (quoted by Burton), writing of Iceland about 1500, stated: "In Iceland are found men of eighty years who have never tasted bread. In this country no corn is grown, and in lieu, fish is eaten."'

Burton, quoting Pearse, states that rickets and caries of the teeth were almost unknown in Iceland in earlier times… The health conditions were good and dental caries was unknown until after 1850. Stefansson exhumed 96 skulls from a cemetery dating from the 9th to the 13th centuries and presented them to Harvard University. They have been described by Hooton (1918), who found no evidence of caries in any of them. There were but three to four defective teeth in the entire series, and these had suffered mechanical injury. During the last half century caries has steadily increased in Iceland.

Modern Iceland had not the isolation of the period which Burton described. There had been a great advance in civilization and population. Fifty per cent of the people now live in towns or trading stations. There are four agricultural schools. Potatoes, turnips, and rhubarb are cultivated. Iceland imports the trade foods, such as flour, sugar, preserved fruits and tinned foods. Caries has become common, as have many other ailments.

That this regrettable decline in health cannot be attributed to the change from country to town life, is proved by a remarkable experiment carried out in Denmark itself during World War I.

The blockade, following the entry of the USA into the war, put the Danes in a very serious position. Professor Mikkel Hindhede, Superintendent of the State Institute of Food Research, was made Food Adviser to the Danish Government to deal with it.

The problem that faced him was this; Denmark had a population of 3,500,000 human beings and 5,000,000 domestic animals. She was accustomed to import grains from the US for both. There was now a shortage of grain foods.

In this crisis Hindhede decided that a drastic reduction in the livestock must be made. So some four-fifths of the pigs were killed and about one-sixth of the cattle. Their grain food was given to the Danes, and it was given … as wholemeal bread with the extra coarse bran that is not put into ordinary wholemeal bread, incorporated.

In addition to this bread, or Kleiebrot, which was made official for the whole country, the Danes ate porridge, green vegetables, potatoes and other root vegetables, milk, butter, and fruit. No grain or potatoes were allowed for the distillation of spirits, so there were no spirits. Half the previous quantity of beer was permitted.

As some pigs were left, the people on the farms got meat; the people in the cities – 40 per cent of the population – got very little meat. Only the rich could afford beef.

The food regulations were begun in March 1917 and were made stringent from October 1917 to October 1918.

The result of this enforced national diet was a remarkable lowering of the deathrate. The deathrate, which had been 12.5 in 1914, now fell to 10.4 per thousand, 'which is the lowest mortality figure that has been registered in any European country at any time'. (Hindhede.)

Hindhede puts this impressive result in another way. Taking the average from 1900 to 1916 as 160, in the October to October year it was 66. Even in men over 65 the figure fell to 76.

Hindhede attributes this extraordinarily rapid and marked change to two things: (1) less meat, (2) less alcohol. He regards the bran as having largely filled the gap of the scanty or absent meat, bran having a good proportion of vegetable meat or protein. He regards the experiment as a triumph for his previous teaching. 'The reader knows,' he writes in the *Deutsche Medizinische Wochenschrift* of March 1920, 'how sharply I have emphasized the advantages of a lacto-vegetarian diet. I am not in principle a vegetarian, but I believe I have shown that a diet containing a large amount of meat and eggs is dangerous to health.'

And yet we have only to turn to another Danish possession (ironically enough) to find a refutation of this rather narrow view.

The north-west coast of Greenland, where the Polar Eskimos live, is within the Arctic Circle. It is the most isolated and the least affected by civilization of these three possessions of Denmark.

Some attempts at gardening have been introduced by the Danes, but previously the only vegetable food the Eskimos got was from the profuse but, in species, limited vegetation of the Arctic summer. Otherwise they lived mainly on sea animals and sea birds. There was no offal. They ate everything that could be eaten. When it was frozen they often ate it raw. The thick, heavy skin of the narwhal is particularly favoured. The millions of sea birds which visit their coast supply a winter store of meat and eggs.

The Eskimos are also exceptionally healthy. 'The fact that the Eskimos of this polar tribe have such excellent physique, hair, and teeth, and such superb health without any trace of scurvy, rickets, or other evidence of malnutrition,' write McCollum and Simmonds, 'is interesting in the light of their restricted and simple diet.'

> It is also interesting as a counterweight to Hindhede and other nutritionists who plump for the excellent lacto-vegetarian diet. There are other excellent diets, and the whole-carcass one of the Polar Eskimos is one of them.

From the far north our next jump is to the Island of Tristan da Cunha in the South Atlantic.

> The people of this island are people of our own race living on the products of sea and soil, most of them have perfect teeth which last them all their lives…
>
> Mr James R. A. Moore, LDS, RCS (Eng), visited the island in 1932 and again in 1937. In 1932 he examined 156 persons and 183 in 1937. Of the 3181 permanent teeth in the former year, there were 74 carious and of the 3906 in the latter year there were 179 carious.
>
> He speaks of the physique of the people as being good. They are well set up, clean and well nourished. The children are breast fed and are not weaned until at least one year old. Fish and potatoes are the staple diet, meat occasionally, milk and butter sufficient. Eggs form a big item of the island diet and are mainly Mollyhawk and penguin. Vegetables are not plentiful, but beetroot, lettuce, beans and onions are now being grown. Imported flour and sugar are regarded as luxuries, but they have been brought in to a greater extent latterly, which may account for the tendency of the teeth to deteriorate.
>
> The fat in adequate amount is provided by rendering down the carcasses of young Mollyhawks and petrels and is used extensively for frying. Sea water is evaporated to provide salt.[5]

It will be seen that the people of this island, also noted for their sound health,[6] have a more varied diet than that of the Eskimo, though like them much of it is derived from the sea. Eggs form a large part of their diet – one of the items condemned by Hindhede. It is worth noting that a marked difference exists between the methods of cooking adopted by the Tristan Islanders and the Hunza, for whereas the latter cook everything together in one pot, the people of Tristan never partake of more than one kind of food at the same time.

For our fourth example of a (once) superlatively healthy race, we must go to the North American Indian of the pioneer days. Observation of these people since they have been forced to live in reservations has been very carefully recorded.

> All who observed the Indians in their primitive state agree that most of them were exceptional specimens of physical development. With few exceptions, however, during two generations, they have deteriorated physically. The reason for this is apparently brought to light by a consideration of the kind of food to which they have restricted themselves since they have lived on reservations.
>
> There is no group of people with a higher incidence of tuberculosis than the non-citizen Indian. As wards of the Government they have been provided with money and land, but have in general shown little interest in agriculture. They have lived in idleness,

> and have derived their food supplies from the agency stores. In addition to muscle cuts of meat they have, therefore, taken large amounts of milled cereal products, syrup, molasses, sugar and canned foods, such as peas, corn and tomatoes. In other words, they have come to subsist essentially upon a milled cereal, sugar, tuber and meat diet. On such a regimen their teeth have rapidly become inferior and badly decayed. They suffer much from rheumatism and other troubles which result from local infections. Faulty dietary habits are in great measure to be incriminated for their susceptibility to tuberculosis.
>
> Other classes of Indians, who have become successful farmers, have not deteriorated as a result of contact with civilization, except in so far as they have suffered from alcohol and venereal infections. The non-citizen Indian has suffered, not because of contact with civilization, but because he has been forced into dietary habits which are faulty. (McCollum and Simmonds.)

In the days of their prime these people subsisted mainly on the wild game of virgin forest and prairie, regions in which the law of return operated fully.

For the last example I go back to the continent of Asia, to the people of rural China. Their diet is nearer to that of the Hunza than to any of the other examples we have looked at. Fruit, vegetables and sprouted grain are staples of both diets, but unlike the Hunza the principal cereal of the Chinese is rice, not wheat, and they also eat meat, birds, fish and eggs. They are in addition, as is well known, great tea drinkers. In common with the other four groups they eat the whole carcass and the whole grain or vegetable. In the matter of preparation they resemble the Hunza in that everything is eaten together. But are we justified in claiming that they are healthy?

Sooner or later all advocates of organic farming cite the Chinese, going so far as to call them the fathers of good husbandry. Their authority for doing so is almost always Professor King's famous book, *Farmers of Forty Centuries*. The critics of the 'organic school', however, challenge the accuracy of King's report. They say that he was only in the country for a few weeks, that the Chinese people as a whole have an abnormally high death rate, and that the whole country is riddled with disease, most of which is sewage borne because the peasants *fail* to compost their human wastes.

I have made great efforts to check these two opposing views. The truth seems to lie in the statement from Lord Northbourne's *Look to the Land*, that 'China presents remarkable contrasts between the best and the worst'. It is a vast country. Undoubtedly conditions are very bad indeed in some areas, particularly in the overcrowded cities, both as regards health and sewage disposal. But there seems equally little doubt that in certain rural areas composting of a very high order, amounting to a fine art, has been practised for centuries. But, however the overall picture should be painted, one fact seems indisputable, namely, that through the operation of the closed cycle (i.e. without the importation of chemical fertilizers) the soil of China has – despite periodic floods and famines – supported a huge population and a high culture for a period of 4000 years. For this reason, I feel quite justified, after having drawn attention to the other side of the picture, in once more quoting King. He was, after all, Chief of the Division of Soil Management in the US Department of Agriculture, and as such a qualified observer, recording facts as he found them. The references to the 'Medical Testament' contain an admirable summary of King's findings, and it is from that document that the following account is taken.

> King frequently inserts into his pages the cheerful, vigorous and healthy appearance of the Chinese lower classes, the Shanghai coolies, 'fully the equal of large Americans in frame, but without surplus flesh'; 'their great endurance', 'both sexes are agile, wiry, and strong' (Hong Kong); 'lithe, sinewy forms, bright eyes and cheerful faces, particularly among the women, young and old' (Canton); 'everywhere we went in China the labouring people appeared healthy and contented, and showed clearly that they were well nourished'. Cheerfulness is, indeed, common to those peasantries who follow the old agricultural ways.
>
> The average of seven Chinese holdings … indicates a maintenance capacity of 1783 people, 212 cattle or donkeys and 399 swine – 1995 consumers and 399 rough food transformers per square mile of farmland. These statements for China represent strictly rural populations. The rural population of the US in 1900 was placed at 61 per square mile of improved farm land and there were 30 horses and mules…
>
> They [the Chinese] have long realized that much time is required to transform organic matter into forms available for plant food, and, although they are the heaviest users in the world, the largest portion of this organic matter is predigested with soil or subsoil before it is applied to the fields. This is at an enormous cost of human time and labour, but it practically lengthens their growing season and enables them to adopt a system of multiple cropping which would not otherwise be possible. By planting in hills and rows with intertillage it is very common to see three crops growing upon the same field at one time, but in different stages of maturity – one nearly ready to harvest, one just coming up, and the third at the stage when it is drawing most heavily on the soil.

This disposes of the theory that increased production and heavy cropping have been responsible in this country for our diseases in crops. The Chinese have been cropping in this way for 40 centuries.

> The Chinese manure or compost is made of everything that can be collected which once got its life from the soil, directly or indirectly. They are mixed together until they form a black friable substance which is readily spread upon the fields. King describes a number of different processes he saw in different parts of China. One he describes as being carried out in compost pits at the edge of a canal, a process entailing 'tremendous labour of body and amount of forethought'. For months before his visit men had brought waste from the stables of Shanghai, a distance of 15 miles by water. This they had deposited upon the canal bank between layers of thin mud dipped from the canal, corresponding to silt collected in and taken from the recesses in the Hunza aqueducts, and left to ferment. The eight men at King's visit had nearly filled the compost pit with this stable refuse and

canal silt. The pit was in a field in which clover, with its peculiar power of taking nitrogen from the air, was in blossom. This was to be cut and piled to a height of five to eight feet upon the compost in the pit, and also saturated layer by layer with canal mud. It would then be allowed to ferment 20 to 30 days, until the juices set free had been absorbed by the winter compost beneath and until the time that the adjacent land had been made ready for the coming crop. The compost would then be distributed by the men over the field.

At another time he saw a compost pit within a village in which had been placed all the manure and waste of the households and streets, all stubble and waste roughage of the fields, all ashes not to be applied directly, mixed up with some soil. Sufficient water was added to keep the contents of the pit saturated and to promote their fermentation. All fibres of organic material have to be broken down, which may require working and reworking, with frequent additions of water and stirring for aeration. Finally the mixture becomes a rich complete fertilizer. It is then allowed to dry and is finely pulverized before it is spread upon the land.

Every foot of land, says King, is made to provide food, fuel, or fabric. 'The wastes of the body, of fuel and fabric, are taken back to the field; before doing so they are housed against waste from weather, intelligently compounded and patiently worked at through one, three or even six months, in order to bring them into the most efficient form to serve as manure for the soil or as feed for the crop.'

These then are the five peoples[7] which either still enjoy an exceptional measure of health, or else until very recently have done so. What have they in common?

Not race, for the groups include white, brown, red and yellow races.

Not climate – there could hardly be greater contrasts than between the plains and hills of rural China or the prairies of North America and the precipitous mountain crags of the northern provinces of India, or than between the frozen north and the luxuriant warmth of Tristan da Cunha.

Not diet – in the ordinary sense – for these range from the lacto-vegetarian diet of the Hunza to the almost purely carnivorous diet of the Eskimo, with almost every variant in between.

Not methods of preparing their food either, for though there are certain resemblances – as between Hunza and Chinese for example – no methods are common to all five.

In fact it seems clear that it is not in *kind* at all that we must look for our common factor, but in *quality*.

All five groups have good air to breathe, but that cannot by itself be the secret of their health, or our own hill and country dwellers would have health to compare with theirs, which, unfortunately, they have not.

The only discernible common factor, other than good air, seems to be that the diets of all five groups are 'whole' diets in the full sense of the word. That is to say: (a) every edible part contained in the diet is consumed; (b) in every case the foods are grown by a system of returning all the wastes of the entire community to the soil in which they are produced. For the sea, too, is a 'soil' in this sense, supporting its teeming population by means of the rule of return – the everlasting cycle of life and decay; (c) all the foods are natural unprocessed foods; and (d) the diets start before life begins; the parent is as healthy as the child.

There is a complete and continuous transference of health from a fertile soil, through plant and/or animal to man, and back to the soil again. The whole carcass, the whole grain, the whole fruit or vegetable, these things fresh from their source, and that source a fertile soil. Herein appears to lie the secret. If this be true, then the answer to our question, put at the beginning of this chapter, would appear to be that *any* diet is a health-promoting diet so long as it conforms to these three rules, and the first of these is a fertile soil.

> The importance of the method of culture of food is primary, radical, and fundamental in the matter of health. It exceeds all other aspects of nutrition – if, that is, one separates any aspect of what is a whole.

In the case of diets based on agriculture, such a view brings us back again to humus farming.

[It also served to emphasize the need for further investigation, and so led to the establishment of the Haughley Experiment.]

Notes

1 Unless otherwise stated, all quotations in this chapter are taken from this book.

2 When Dr Wrench wrote this, he was clearly unaware of the intensive study of health carried out by Drs G. Scott-Williamson and Innes Pearse known as 'The Peckham Experiment', and the definition of health that resulted from it. (See Part II, also new introduction to Part I.) So far, however, this extremely important and inspired piece of research remains the only investigation of its kind ever to have been undertaken.

The Nutrition Transition and its Health Implications in Lower-income Countries

Barry M. Popkin

Human history is characterized by a series of changes in diet and nutritional status. This pace of change has quickened considerably over the last three centuries.[1,2] Before that, major changes in diet and nutritional status occurred infrequently and one could argue that there were relatively few changes in diet for the first several million years of existence of the human race. This article focuses mainly on current stages in the nutrition transition. The concept of transitions or movement from one state or condition to another is used to capture the dynamic nature of diet, particularly large shifts in its overall structure. Many of the same factors that explain shifts in diet also explain those in physical activity and body composition. This work is based on the premise that the transition to the age of degenerative diseases is avoidable and that an understanding of the patterns and sources of change will serve as a basis for future interventions at the population level to lead to more healthful transitions.

A similar concept of transitions is embodied in the theory of the demographic transition – the shift from a pattern of high fertility and mortality (typical of less developed countries decades ago and of 18th-century Europe) to one of low fertility and mortality (typical of modern industrialized nations today). Even more directly relevant is the concept of the epidemiological transition, which focuses on changes in patterns of disease and causes of mortality. As first conceptualized by Omran,[3] the epidemiological transition moves from a pattern of a high prevalence of infectious diseases and malnutrition to one in which chronic and degenerative diseases predominate. Accompanying this progression from an earlier stage of pestilence, famine and poor environmental sanitation to the later stage of chronic and degenerative diseases strongly associated with life-style, is a major shift in age-specific mortality patterns and life expectancy. Both of these concepts of transitions share a focus on how populations move from one stage or condition to the next.

There have been large changes over time in diet and physical activity, especially their structure and overall composition. These changes are reflected in nutritional

Reprinted from Popkin B. 1998. The nutrition transition and its health implications in lower-income countries. *Public Health Nutrition* 1(1), 5–21.

outcomes such as stature and body composition. Furthermore, these changes are paralleled by changes in life-style and health status, as well as by major demographic and socioeconomic changes. For example, during the early stages of human evolution (from about 3 million to about 10 thousand years ago), human subsistence was based primarily on a pattern of gathering, scavenging and hunting. The diet these early humans consumed was varied, low in fat and high in fibre. Physical activity levels were high. In consequence, early *Homo sapien* hunter-gatherers tended to be taller and more robust, and suffered fewer nutritional deficiencies than humans who lived in settled communities during the period of early agriculture. These early agriculturalists' diet was much simpler and subject to tremendous fluctuations. After 10–12 thousand years of this second stage, the Industrial Revolution and a second agricultural revolution led to a considerable reduction of problems of famine, large shifts in diet and increased stature. This period was followed by a marked shift to the high-fat, refined carbohydrate, low-fibre diet which marks most high-income societies today. Also, an increase in obesity and all the degenerative diseases of Omran's final stage occurred. There is some indication that a new stage of behavioural change related to the reaction to man-made diseases is occurring in selected populations. These five periods are:

- the age of collecting food;
- the age of famine;
- the age of receding famine;
- the age of degenerative diseases;
- the age of behavioural change.

For this article, I focus mainly on the periods that relate to the circumstances most lower- and middle-income countries face – that is, a period where famine has receded and degenerative diseases are rapidly emerging.

The theory of the nutrition transition posits that these changes or stages relate to the complex interplay of changes in patterns of agricultural, health and socioeconomic factors, among others (for further detail see Popkin[1,2]). For this article, the major issues that are considered are demographic and economic changes.

The emergence in the last quarter of the 20th century of obesity as an epidemic among higher-income countries is acknowledged and has been of great concern in these countries. While the specific effects of the shifts in the patterns of diet and activity vary from population to population, both are important. We now face the emergence of obesity as a worldwide phenomenon affecting the rich and middle-income people alike in middle-income countries and also affecting countries previously considered to be poor. This emergence and prevalence of obesity, with all its related health complications, is felt to have major health complications. I note later in the article that this obesity epidemic has been linked in low- and middle-income countries with a rapid increase in the prevalence, as well as earlier age for the onset, of non-insulin-dependent diabetes mellitus (NIDDM). Other well-known complications of excess adiposity which are not discussed include coronary heart disease, many cancers and a large proportion of disabling osteoarthritis.

The attention given by the food and nutrition communities in countries such as China, Brazil and many lower-income countries has focused on problems of under-nutrition but information is presented here to indicate an emerging paradigm with obesity being the dominant problem or with an ever-increasing obesity problem coexisting with one of dietary deficit. Furthermore, these rapid shifts in obesity, caused by shifts in diet and activity, are linked with rapid increases in NIDDM and other related chronic diseases. This increase is found in countries whose populations are more genetically susceptible and in other nations. This combination of very rapid shifts in diet and activity and the emergence at very early stages of economic improvement of high rates of chronic disease forces us to focus attention on this topic.

After a brief introduction to the data and measures, the article first introduces the major underlying social and demographic changes, then the dietary and physical activity changes, followed by a discussion of the evidence of the obesity epidemic and NIDDM as it relates to this transition.

Methods

Data

Data came from a large number of sources, mainly nationally representative or large nationwide surveys. In addition I use national data sets such as food balance sheets and national income accounts.

A thorough presentation is made of the China Health and Nutrition Survey (CHNS), an ongoing, longitudinal survey of eight provinces in China. A multistage, random, cluster sampling procedure was used to draw the sample from each province. Additional detail on the research design of this survey is presented elsewhere.[5]

For some of the information on obesity patterns and trends, the focus is mainly on larger and more representative samples of adults. Our selection criteria for presenting data from other surveys was size, sampling design and geographic area. If a study was representative of a region or country, it was always used. If it came from a region with few studies and did not fit the criteria of national representativeness, I used it if the sample size was large and it seemed reasonably representative. Note that I use the term region only to fit a cluster of countries and not an area within a country.

National food consumption data came from the Food and Agriculture Organization of the United Nations (FAO) food balance sheets for the period 1962–1990, now available in the FAOSTAT database.[6] Data on food availability are combined to express in percentage terms daily energy from macronutrients, with the official estimates of gross national product (GNP), as established by the World Bank.

Measures

For the national food consumption and economic pattern analysis, GNP per capita was expressed in 1993 American dollars to allow for an easier comparison of the results. Regression analyses were used to relate dietary data (the proportion of energy from vegetable and animal fats, carbohydrates, caloric sweeteners and protein) for those countries for which full sets of data were available in 1962 and in 1990 to the logarithm of per capita GNP. This research used all countries for which both sets of data were available – 98 in 1962 and 133 in 1990. These results were not changed when looking only at a set of countries with full sets of data in both 1962 and 1990.

The regression analysis also included an urbanization variable. Although GNP and the extent of urbanization were closely linked before World War II, this is clearly no longer the case and many lower-income countries now experience very high rates of urbanization. Throughout the text the term lower income is used to describe a quite heterogeneous group of nations. In addition, the term less and more developed nation is used in this article interchangeably with lower income. In the regression analyses, the percentage of energy from each macronutrient was regressed on GNP per capita, the proportion of the population residing in urban areas that year, and an interaction term between GNP per capita and the proportion of urban residents. All variables in this regression were highly significant.

Body mass index (BMI) is the standard population-based measure of overweight and obesity status. For adults, the cut-offs used to delineate obesity are less than 18.5 for thinness (chronic energy deficiency), 18.5 to 24.99 for normal, 25.0–29.99 for overweight grade I, 30.0–39.99 for overweight grade II, and 40.0 and above for overweight grade III.[7] For this article, grades II and III are combined.

Factors Underlying the Nutrition Transition

It is useful to consider demographics and economics, two of the propositions that affect diet and activity which are changing very rapidly.

Proposition 1: Major shifts in population growth, age structure and spatial distribution are closely associated with nutritional trends and dietary change

No attempt is made here to address all aspects of this proposition but rather to focus in some detail on one of the most powerful sets of shifts linked with demographic change – rapid urbanization. Evidence indicates a most pronounced association of urbanization with the shifts in diet and activity and body composition.

People living in urban areas consume diets distinctly different from those of their rural counterparts. City dwellers have led the movement from the pattern of famine to the patterns of receding famine and the rise of degenerative disease. Compared with rural diets, urban diets show trends toward consumption of the following:

- superior grains (e.g. rice or wheat, rather than corn or millet);
- more milled and polished grains (e.g. rice, wheat);
- food higher in fat;
- more animal products;
- more sugar;
- more food either prepared away from the home or processed.

The potential impact of urbanization on diet structure is shown by this regression model. The model used FAO food balance sheets and World Bank economic indicators data for 1990. The regression relating GNP per capita to the outcomes of energy from each food source includes as a covariate the proportion of residents residing in urban areas and an interaction between the proportion urban and GNP per capita. For the purposes of clarification of the impact of shifts in urbanization, the results of those regressions were used to predict (simulate) the diet structure with the proportion of urban residents worldwide at either 25 or 75 per cent. As shown in Figures 12.1 and 12.2, for higher rates of urbanization, the simulation developed from our model predicts a substantial increase in the consumption of sweeteners and fats. The clear implication is that a shift from 25 to 75 per cent

Figure 12.2 *Relationship between the proportion of energy from each food source and gross national product per capita with the proportion of the population residing in urban areas placed at 75 per cent, 1990*

urban population in very low-income countries would be associated with an added four percentage points total energy from fat and an additional 12 percentage points energy from sweeteners.

When analysis is undertaken at the country level, it is clear that these contrasts between urban and rural eating patterns are more marked in lower-income than in higher-income countries. In higher-income countries, market penetration into rural areas is common, and nationally integrated food distribution systems exist. Nevertheless, higher-income countries show important urban–rural differences in eating patterns, especially in consumption of food prepared away from home[8] and responsiveness to information and the influences of mass media. Even in higher-income countries, large differences between urban and suburban food and labour markets, in combination with other factors related to residence, result in distinct dietary and nutritional status patterns.

Key factors responsible for urban–rural differences in dietary intake and resulting differences in nutritional status include:

- better transportation and marketing systems in urban areas that provide greater availability of food during periods of seasonal shortage;
- greater penetration of marketing activities of the processed commercial food sector into the denser urban markets;
- greater heterogeneity of urban populations with respect to dietary pattern;

- different occupational patterns, characterized in urban areas of reduced compatibility of jobs with home food preparation and child and elder care;
- different household structures related to a wide range of economic and social factors;
- different disease and health service use patterns.

(For a more detailed review of dietary aspects of urbanization, see Popkin and Bisgrove.[9])

Key dimensions of world urbanization

Several major demographic shifts began in the post-World War II period and continue unabated and have even accelerated in some regions. One is the vast increase in the proportion of persons who reside in urban areas. A second is urban agglomeration. A third is the shift of poverty toward the urban areas, particularly toward squatter and slum areas.

Proportion living in cities

Urban growth was relatively modest before the Industrial Revolution. Rapid urban development first occurred in the higher-income countries; now, lower-income countries are undergoing even more rapid urbanization. In the last half of the 20th century, urbanization resulting from migration and natural increase has become a dominant factor in all regions and shows no signs of abating. The proportion of persons living in urban areas in developed and developing countries has changed significantly since 1950. Table 12.1 shows that the higher-income world is comprised predominantly of urban residents today which is not the case for the less developed and poorest least developed countries.[10] Nevertheless, by 2025 urban residency will be the common form of residence throughout all but the poorest African countries.

The continuation of the migration of rural residents to urban areas more than offsets the much lower urban fertility rate and leads to the quite different patterns of growth in urban and rural areas. Table 12.2 shows that these patterns accelerate in the next century.

Concentrated population growth

Urban growth, particularly in lower-income countries, has been skewed towards a few larger cities, often called urban conglomerates. These cities of 5–27 million dominate many countries and are growing much faster in the less developed than in the more developed regions of the world. Nevertheless, in the lower-income world, more than half of the urban residents reside in smaller and medium sized cities with populations less than 500,000.[10] As is seen in Table 12.3, the most explosive growth of these mega-cities is in Asia.

Table 12.3 *Mega-cities, number 1970–2015*

More developed regions	6	6	6	6

Note: Mega-cities have 8 or more million residents.

Source: United Nations: Population Division, 1995[10]

Shift in the proportion of poor to the cities

Concomitant with increased concentration of the population in urban areas is a dramatic shift in the proportion of poor people living in cities. In absolute and relative terms, the majority of the poor of the lower-income world live in cities. By the year 2000, it is estimated that 57 per cent of the poor will live in urban areas.[9,11] Estimates of the distribution of the poor are rare. The one used by the World Bank was the subject of extensive research. While it is old, it is felt to be more carefully prepared than many more current projections. However, it is estimated that a majority will reside in dense slums or makeshift dense squatter settlements. At the same time a disproportionate share of the upper income and upper-middle income population also lives in urban areas.

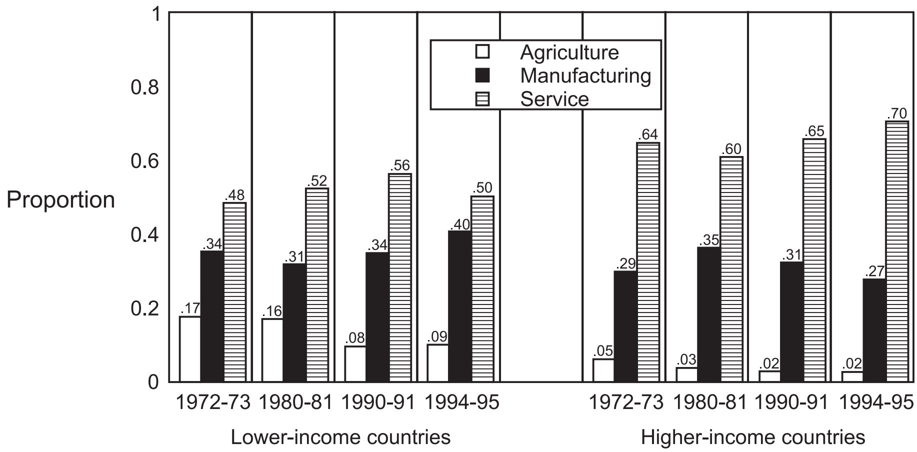
Migration

An important dimension of urban growth is its associated pattern of migration. Migration from rural areas to cities (and to a lesser extent from small to larger cities) and international migration have affected diet profoundly. For example, populations of Samoans who moved to San Francisco, Polynesians and Maori who moved to New Zealand, Japanese who moved to the US and Yemenite Jews who moved to Israel all showed large changes in diet, followed by large increases in diet-related chronic diseases.[12–15]

In other research, a national survey of American adolescents examines the effects of generation of birth in the US. In this work, first-generation Americans are defined as those born outside the US. It was found that there is more than a doubling of obesity of Asian-American and Hispanic adolescents between the first-generation and second-generation Americans (those born in the US). With about 3400 Hispanics and over 2000 Asian-Americans in the nationally representative sample, the likelihood of being obese increased from 23.2 to 32.6 per cent among Hispanics going from the first to second generation and 10.7 to 24.6 per cent for Asian-Americans. The 85th percentile reference[7] was used for obesity.[16] As discussed below in reference to the Barker metabolic programming hypothesis,[17,18] it is possible that the increased obesity in these immigrants is explained partially by fetal and infant nutrition insults: however, we feel that there is potential for an independent environmental component which may explain this American experience.

Proposition 2: Changes in income, patterns of work and leisure activities and related socioeconomic shifts lead to changes in women's roles and shifts in dietary and activity patterns

A major change in economic structure associated with the nutrition transition is the shift away from a pre-industrial agrarian economy and towards increasing industrialization. This transformation then accelerates; the service sector grows



Source: World Bank, 53 countries, over a 23-year period

Figure 12.3 *Shifts in the distribition of occupation, 1972–1995*

rapidly, industrial production is dominated by capital-intensive processes and time-allocation patterns change dramatically. Associated socioeconomic changes especially important in the nutrition transition phenomenon are (a) changes in the role of women (especially with respect to patterns of time allocation); (b) changes in income patterns; (c) changes in household food-preparation technology; (d) changes in food production and processing technology; and (e) changes in family and household composition.

The sectoral distribution of the labour force towards industry and service has accelerated around the world. Figure 12.3 presents data on this pattern for higher- and lower-income countries. It shows for all lower-income countries a pronounced move away from agriculture and towards manufacturing and service employment. As has often been shown, the most labour-intensive agricultural work requires the greatest amount of energy expenditure. One of the most inexorable shifts with modernization and industrialization is the reduced use of human energy to produce more capital-intensive manufacturing and goods and services. The result is obviously a marked shift in activity patterns at work, a trend particularly associated with our shift into increasingly capital-intensive production and increasingly sedentary manufacturing, service and commercial work. This within-occupation shift in energy expenditure cannot readily be shown with national data. It requires individual level information.

Unfortunately, few longitudinal studies attempt to measure physical activity and energy expenditures. One quite simple measure of overall activity has been collected in each survey from 16,000 Chinese as part of the CHNS. Table 12.4 shows the shifts in the proportion of Chinese adults involved in low levels of physical activity at work. In particular, urban residents in all income groups were more likely in 1993 to have adopted a more sedentary activity pattern. Elsewhere,

Table 12.4 *Distribution of physical activity of Chinese aged 20–45 years, by thirds of household income and residence, CHNS 1989, 1991 and 1993*

	Household income per capita thirds								
	Low			Middle			High		
	1989	1991	1993	1989	1991	1993	1989	1991	1993
Urban residence									
lowest level activity	23.7[b,]**	34.3[b]	42.6	35.5*	45.4	42.8	44.5*	58.3	55.5[a]
middle level activity	49.6[b,]*	30.1	30.2	46.1*	39.7[a]	40.6	48.0*	34.5	32.0[a]
highest level activity	26.7[b]	35.6[b,]*	27.2	18.4	14.9	16.6	7.5	7.2	12.5[a,]*
Rural residence									
lowest level activity (%)	15.3*	3.9[b]	4.8[b]	16.2*	12.3	12.6	23.7[a]	24.8	19.8
middle level activity (%)	22.2[b,]**	5.3[b]	7.9[b]	28.9*	14.1	13.3	35.2*	24	26.8*
highest level activity (%)	62.5[b,]**	90.8[b]	87.3[b]	54.9*	73.6	74.1	41.1*	51.2	53.4

[a] The proportion differs significantly from middle- and high-income groups within same year ($P < 0.05$).
[b] The proportion differs significantly among three income groups within same year ($P < 0.05$).
* The proportion differs significantly from corresponding value in other 2 years ($P < 0.05$).
** The proportion differs significantly from corresponding value among the 3 years ($P < 0.05$).

this is linked with significant increases in BMI and obesity.[19] In contrast, this pattern was not seen in the rural areas. In fact, rural residents, particularly low-income ones, showed a significant change from low and moderate activity patterns towards a high physical activity pattern and related to that, an increase in chronic energy deficiency measured by a BMI below 18.5.

Related to the effect of industrialization and modernization on market production is a similar shift in time allocation and physical effort in home and leisure activities. Since the discovery of fire, a key thrust in the continuing development of household technology for processing and storing food has been to save time and enhance the quality of life. In the last century, the evolution of household technology seems to have accelerated. In food-preparation technology, recent developments include efficient ways to prepare and store food (canning, refrigeration, freezing, radiation treatment, packaging, etc.); food processing with tools such as electric mixers and food processors; and cooking with pressure cookers, cookware made with improved metals and alloys, metal stoves using various fossil fuels, and microwave ovens.

These food-preparation technologies, together with home electrification, washing machines and clothes dryers, vacuum cleaners, piped water, and so forth have transformed home production from a time-consuming, often back-breaking, full-time occupation for peasant or working-class women. Although home production still requires time and energy, purchased technology where accessible can help save time for those who engage in home production activities. One way to see how these household technologies have made transformations in a society is to examine the studies of the introduction of electricity to agricultural societies, which show large, rapid transitions in the use of time, the roles of various household members and other social factors.[20] Herrin's classic study on the impact of electrification on the lives of families in poorer regions has demonstrated the profound shift in the use of time related to the use of electricity.

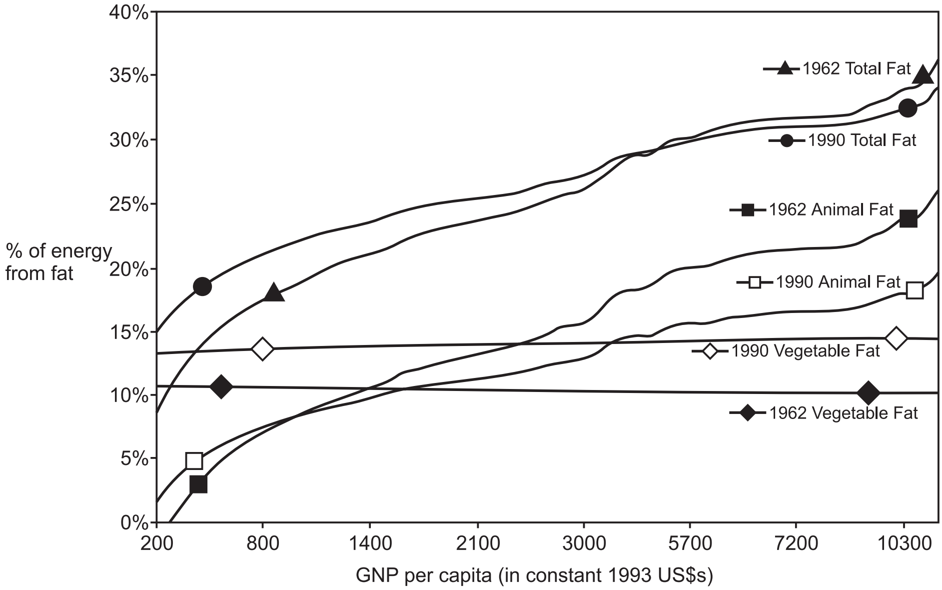
Possibly an even more astounding shift has come in leisure activities. In the past, leisure activities for children often meant active play, but leisure today may mean a quite sedentary activity such as watching television or playing a computer game. Documentation of such patterns across the lower-income world is not available in terms of time spent and the shift in activities. This area needs greater focus.

Income patterns

Income is an important element in the nutrition transition because it measures control over the flow of goods and services. In other words, income allows one to purchase goods or services that can affect diet and activity, and nutritional status. Three key issues relating income to nutrition are (a) the effect of income changes on dietary structure; (b) the effect of income changes on the amount of energy, protein and fat consumed; and (c) the effect of change in the structure of the economy, particularly the change to commercial agriculture on the nutritional status and diet of subsistence agriculturalists. The effect of income in purchasing the assets and technologies that in turn affect time use, diet and activity patterns noted above, is equally important but not discussed here.

As Figures 12.1 and 12.2 show, increasing income is strongly associated with changes in the proportion of energy in the diet from various sources. What has been shown more recently, however, is that the strength of the income and dietary fat relationships have been somewhat uncoupled at the national level. Figure 12.4 presents a regression of the proportion of total, vegetable and animal fat on GNP. The results show a strong flattening of the relationship and a shift towards much higher consumption of dietary fat among poor nations than was previously known. In other words, lower-income countries are now able to afford the types of higher-fat diets that previously were accessible only to middle-income countries.

These relationships between income and diet noted in Figures 12.2 and 12.3 have an important culture-specific component. The responsiveness of dietary total energy, total and saturated fat, and other macro- and micro-nutrients to income change depends upon the nature of the demand for particular foods and by overall eating patterns. For example, in the Philippines, the coconut palm is a major source of cooking oil, and income increases are associated with increased away-from-home consumption of foods that are frequently fried; thus, saturated fat and total fat consumption are highly responsive to income increases, particularly those accruing to women.[21,22] Similarly, in China, pork consumption is highly responsive to increases in income, which thus result in large increases in the proportion of energy from fat.[5,23,24] In contrast, where income increases are spent on more elaborate packaging and processing or higher quality of specific foods, rather than



Source: Regressions run with food balance data from FAOUN; GNP data from the World Bank

Figure 12.4 *Relationship between the percentage of energy from fat and GNP per capita, 1962 and 1990*

larger quantities of food or shifts in the types of foods, changes in income will have less effect on dietary structure.

A related point is that while the GNP–fat intake relationship has flattened, it is shown elsewhere that there remain in all countries important relationships between income and fat consumption at the individual and household level.[25]

A second apparent relationship between income and diet is that as income increases (beyond the point where total food energy needs are met), people spend more per food item,[26] partly to obtain higher quality. As many authors have shown, food demand is much more price- and income-elastic among the poor than among higher-income groups.[26,27] Changes in diet with increased income also relate to the reduced time needed to consume higher quality and higher priced goods that have undergone more processing before purchase.[28]

Income has been and will continue to be an important identifier of groups at risk of either nutritional deficiency or nutritional excess. Income and more complex measures of socioeconomic status that incorporate other dimensions of social and economic well-being, such as education, asset ownership, occupation and various more qualitative measures of 'status', are useful in identifying problems of deficit in all societies and problems of excess associated with the pattern of degenerative disease.

For lower-income countries, a crucial dimension of the relationship between socioeconomic status and nutrition is the distribution of chronic disease risk factors by income group. In higher-income countries, the poor are far more likely to suffer from obesity, NIDDM, coronary heart disease (CHD), and other chronic diseases.[29,30] This has not been found in lower-income countries, although this pattern is slowly changing. For instance, a recent World Bank study on adult health in Brazil[31] indicates that where income constraints among the poor are not too severe, many risk factors for cardiovascular disease will likely be greater among the poor than among the rich. This inverse income-obesity relationship is beginning to be found in larger sub-population groups in Brazil[2] and in other Latin American countries.[32] Within the next 10–20 years, in most of Latin America and many parts of Asia, obesity and NIDDM will become problems of poverty. There are already indications that this is occurring in South Africa.[33] The rapid increases in obesity found in lower-income countries are discussed below together with the consequences of this change.

Intermediate Factors: Diet and Physical Activity

While nutrition researchers have typically focused on the study of diet, it is no longer the only issue of concern. Diet and physical activity are intertwined, and interactions between energy intakes and expenditures are amenable to intervention. It may very well be that the rapid reduction in physical activity rather than diet explains as much or more of the increased obesity facing lower and transitional income countries. Research is needed to quantify the relative impact of each set of factors.

Physical activity

As noted above, the remarkable shifts in occupations and in travel to work along with changes in the nature of home production and leisure activity have had profound effects on activity patterns throughout the world. Few studies have measured this shift in activity and energy expenditures. One quite simple measure of overall activity has been collected in each survey from 16,000 Chinese as part of the CHNS. It has been reported elsewhere that a remarkable shift in activity patterns for adult Chinese occurred between 1989 and 1993 as shown in Table 12.4.[2]

Structure of diet

Most researchers have focused on the shift from diets high in complex carbohydrates and fibre to those with a higher proportion of fats, saturated fats and sweeteners. But underlying these broad patterns are major shifts in the type of staples selected, and in the overall diversity of the diet. In most countries one of the first shifts is from lower quality or inferior staples to those deemed to be of higher quality.

In one country lower quality might be millet, in another it might be sorghum or cassava. This shift is accompanied or followed rapidly by the decline in the proportion of energy from these basic staples.

The work undertaken to date on this nutrition transition seems to show remarkable congruity in the broad shifts in diet and in the ever-increasing shift towards higher-fat diets in all regions of the world. Little has been done systematically to lay out the role of the array of socioeconomic, technological and other factors that explain this shift. The best work has been done on the role of urban residence (e.g. the work of Bourne et al[34,35]) and its relationship to eating habits.

The shifts in the proportion of energy from fat, protein and carbohydrates provide some sense of the broader shift. At the country and individual level, studies have been conducted in China[5] and Brazil[36] to provide examples and present information from a selected set of food groups from China to highlight the food shifts. As shown in Table 12.5, there is a marked shift away from grains and tubers towards fats, meat and eggs amongst other things. In addition, there are marked differences in the diets of lower-, middle- and higher-income thirds in this country with a much smaller income distribution than is found in many countries. Table 12.5(a) presents the average intake for each food for low-, middle- and upper-income adults in 1989 and then presents the change for these adults over a four-year period. Table 12.5(b) presents the proportion who consume each of these foods and the shift in the proportion (percentage points) who consumed them between 1989 and 1993. Essentially this table shows that lower-income adults consume more carbohydrates and vegetables and less meat, eggs and oils. Moreover, over time there is a pronounced trend towards a reduced consumption of grains, tubers and corn products, and an increase in consumption of meat and meat products, eggs and oils.

Table 12.5(b) shows that while per capita intake is changing markedly towards higher intake of fats, eggs and meats, a greater proportion of individuals is consuming many grain and vegetable products. In this table, a food grouping system is used that was developed to separate the Chinese food composition table into 33 distinct food groups. Then the number consumed by each person is added up to present mean intake and the proportion with high and low numbers of food groups consumed. It is noteworthy that there is a marked increase in diversity of the Chinese diet, but the total amount consumed of many starchy staples and other higher fibre and nutrient-rich plant-based foods is being rapidly reduced.

It is essential not to ignore the benefits of this shift. The new Chinese diet is more diverse and linked to reduced under-nutrition. This trend towards a more diverse diet is seen systematically in most countries in Asia, Africa and Latin America. The diet of grains and tubers mixed with small amounts of condiments, possibly a few legumes and a small amount of meat/fish/poultry is clearly not the diet desired by the population. Using our China-UNC-CH food grouping system of 40 groups, with alcohol and condiments removed, the shift towards a more diverse diet is seen by examining the move from a very low diversity to a highly diversified diet in Table 12.6. Over time, the proportion of Chinese of all income groups who

Table 12.5(a) *Changes in Chinese food consumption categorized by income group*

consume very few food groups (five was selected) has declined while those who consume more than ten increases.

Body Composition

One consequence of this nutrition transition has been a decline in under-nutrition accompanied with a most rapid increase in obesity. In all age groups, there is evidence of a rapid increase in obesity and also an array of dietary excess and body composition-related health outcomes such as glucose intolerance and diabetes. Monteiro et al[36,37] (also Monteiro, forthcoming[38]) has documented this shift away from undernutrition most clearly for Brazil.

Programming – a potential link

David Barker and colleagues at the University of Southampton[17,18] have brought into the mainstream the notion of metabolic programming: that early insults operating at a critical period in development result in long-term changes in the structure or function of an organism. In the case of obesity, the hypothesis is that fetal growth retardation results in metabolic changes that are adaptive under nutritionally stressful circumstances *in utero*. A similar argument can be made for postnatal growth retardation manifested as stunting. As the child grows, the metabolic efficiencies that served well in conditions of under-nutrition become maladaptive with over-nutrition, leading to the development of abnormal lipid profiles, altered glucose and insulin metabolism, and obesity.

One reason why the programming hypothesis is so powerful for health relates to its effects on the distribution of obesity. There appears to be the potential for increased visceral adiposity. That is, the literature that has linked metabolic programming with obesity has also shown a greater likelihood of increased waist–hip ratio and other measures of visceral or abdominal obesity. A separate literature has demonstrated that increased visceral adiposity is linked with NIDDM, CHD and stroke.[39]

In other work, four nationally representative samples of children (or a nationwide one for China) show that indeed there is potential that this hypothesis represents a critical link between the foetal and infant insults associated with underdevelopment and the transition towards a lower activity/higher-fat diet associated with the nutrition transition.[40] In fact, without this transition in diet and activity it would not be possible for the biological effects associated with metabolic programming to lead to abnormal lipid profiles or obesity.

The high level of child obesity in China, Russia and South Africa in comparison with National Health and Nutritional Examination Survey (NHANES) III is discussed elsewhere.[40] The really solid causal work on this metabolic programming relationship and any mechanisms that might explain it or Barker's hypothesis is either in process or remains to be undertaken. If this most significant relationship, often termed the programming effect, is as important as the early descriptive results indicate, then this represents an ominous warning regarding infant health. Low-income countries with high fetal and infant malnutrition rates, must make particularly rapid programme and policy shifts to address these additional undesirable consequences of the nutrition transition.[41]

As issues of obesity and later NIDDM are presented below, it is important for the reader to be aware of this hypothesis and its potential for explaining, among other issues, the higher NIDDM levels found in newer urban residents in black South Africa and the parts of the increases in NIDDM elsewhere in Latin America, Asia and Africa.

Prevalence in Lower- and Middle-income Countries

Limited information is presented on obesity patterns and trends in lower-income countries. The focus is on a few cases and the reader is directed to a more thorough review for more detail. Data from Asia and Latin America for adults are presented in Figures 12.5 and 12.6. We look at three measures of obesity, grade I, grades II and above, and the total of all grades. The ages for these data vary slightly but generally are presented for age 20 years and above.

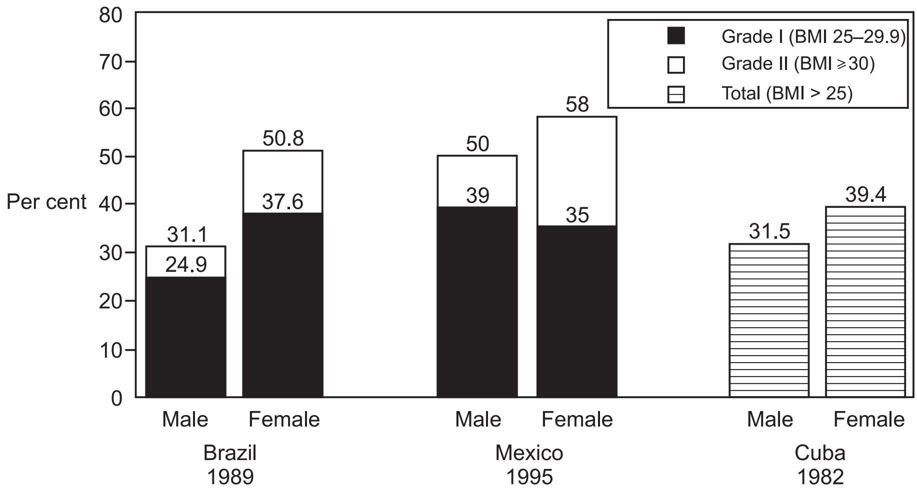

Figure 12.5 *Obesity patterns in Latin America*

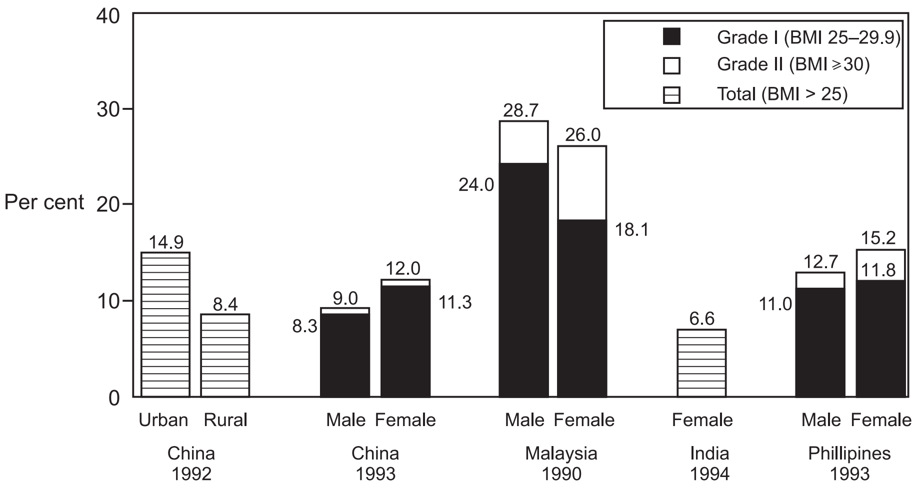

Figure 12.6 *Obesity patterns in Asia*

Latin America

When looking at grades I and II and above obesity measures for Latin America, levels of obesity in the 30 and higher range are found in Brazil, Mexico and Cuba. The range is lower in other South American countries but there is no nationally representative survey for most countries. In Brazil and Cuba, women have higher levels of overweight and obesity than men but this is reversed in one survey in Mexico conducted in 1995. There are few data available in terms of large-scale surveys in the Caribbean; however, other studies and the Cuban data presented here indicate that the Caribbean nations have very high levels of obesity.[42]

Asia

There is still much less obesity in the largest two countries in Asia, China and India, but levels are higher in other countries. For instance, total grade I and above levels are between 25 and 30 per cent for Malaysia, and 13 and 19 per cent for the Philippines. The exceptions are the Central Asian countries such as Kyrgyzstan that were members of the Soviet Union prior to 1992. Grade I overweight status is currently the major problem in Asia except for Malaysia. There is no clear gender pattern to levels of obesity in Asia.

Trends

There are a small number of lower- and middle-income countries for which we have excellent data on trends in body composition. Nationally representative or large nationwide data sets are available for Brazil in Latin America; China and India in Asia; Mauritius in Africa; Nauru and Western Samoa in the South Pacific; and Russia. These provide some sense of trends in adult obesity. Figure 12.7 shows the trends for the few countries for which there are nationally representative data. We created ten-year changes in the percentage points of obesity for each. Much greater detail of these obesity patterns and trends are presented elsewhere.[43]

Brazil

Monteiro and his colleagues[36] have shown that during a 15-year period, the proportion of grade II and above overweight adult males almost doubled (5.7–9.6 per cent). For females of reproductive age the proportion of grade II obesity increased

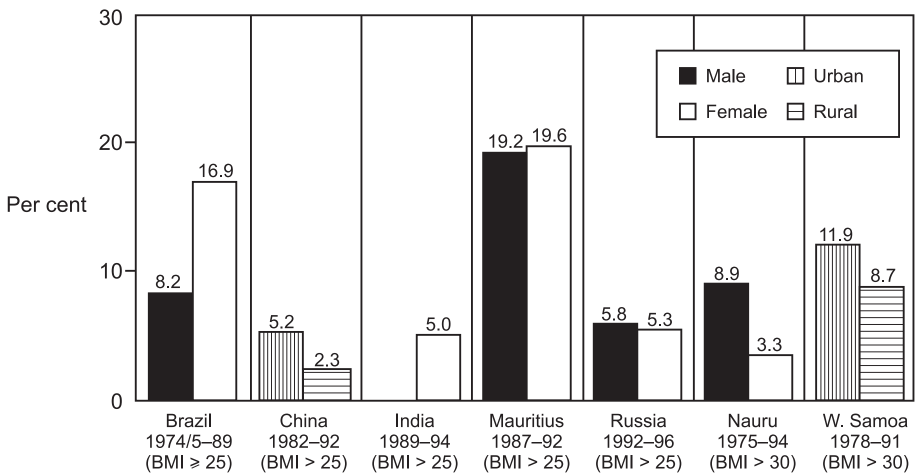

Figure 12.7 *Obesity trends: the percentage point increase in obesity prevalence per ten-year period*

by 230 per cent over a 21-year period. Interestingly, it was shown that the ratio between the underweight and overweight prevalence, a measure of the relative importance of each problem in the population, was dramatically affected between 1974 and 1989. In the case of all adults, the ratio was even reversed: in 1974, underweight exceeded overweight by 1.5 times while in 1989 those overweight exceeded the underweight by more than twice. These increases in the frequency of overweight occur for all incomes and both sexes, but they tend to be far more important among the poorest families.[36]

China

The shifts in diet, physical activity and overweight status in China are among the most rapid ever documented. The level of overweight status in China among adults is still low but the marked shifts in diet and activity and grade I overweight lead one to believe that major increases in grades I and II overweight will occur. These changes are much greater among urban residents of all income backgrounds and among middle- and higher-income rural residents.[19] In China we are able to explore the trends by income group for the 1989–1993 period and have found that the rate of increase among the urban and rural lowest income third is the greatest.

The rates of increase based on national nutrition surveys in China in 1982–1992 indicate a moderate rate of increase; however, this hides the more rapid shifts in diet, activity and obesity seen in the last few years.[44] The increase in the prevalence of 5.2 percentage points of grade I overweight during this ten-year period in urban areas is considerable. During the more recent period, the CHNS data for 1989–1993 show that there has been a consistent increase in obesity in urban and rural areas among adults. The CHNS 1989 survey results for this age group fit exactly in the middle of these results. Grade I and above obesity increased from 9.7 per cent in 1982 to 14.9 per cent between 1982 and 1993.

India

Unlike China, far fewer data are available for India. Information is available only for women of child-bearing age which indicates a small increase over the 19 years but a more rapid increase of 4.2 percentage points during the 1989–1994 period.

Russia

Russia has one of the highest rates of mortality related to CHD in the world. Despite shifts towards a lower-fat diet in the post-reform period, there is evidence of an increase in adult obesity. Data have been collected for seven rounds of the nationally representative Russian Longitudinal Monitoring Survey and there is over time a consistent increase in adult and also elderly obesity.[43] Figure 12.8 presents information on trends in body composition in Russia. The remarkable

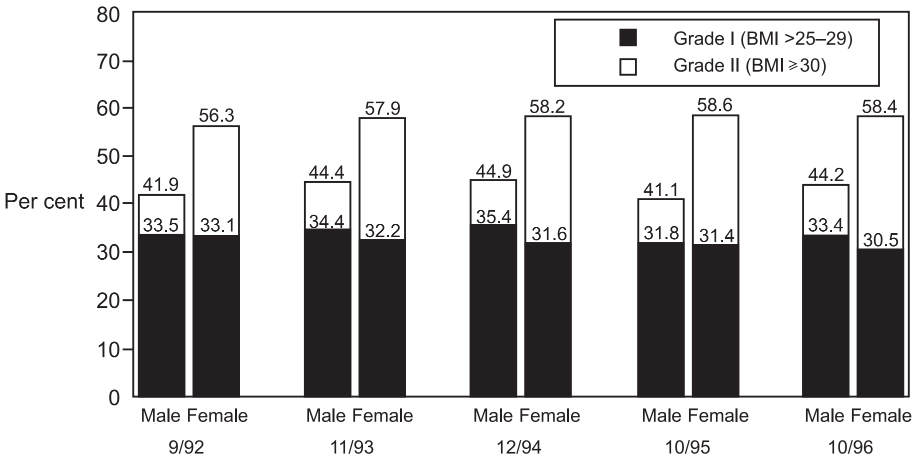

Figure 12.8 *Obesity trends in Russia, 1992–1996*

point to note is that the effects of the economic hardship in Russia have not been seen in the obesity trends. In 1996 the grade II obesity of females showed a decline. A much higher rate of increase in prevalence of obesity was found among grade II and above obesity for Russian females. Overall, the increase in total obesity is over five percentage points per ten-year period for Russia but future directions of this trend are less clear because the economy is in such flux.

The Health Implications: NIDDM and Related Conditions

A range of changes in health are accompanying the nutrition transition. As noted above, foremost is the reduction of infant mortality – and related to that is undernutrition. Wasting is being rapidly reduced in many countries and rates of stunting are also being lowered though recent information indicates that the rate of change has slowed considerably in the last few years.[45] At the same time, many adverse changes are taking place. The positive effects are not addressed here – effects that must not be lost nor minimized. Rather the focus is on the other side of the coin – the negative health effects which represent the most lasting and costly side effect of the nutrition transition.

There is a growing literature that documents rapid increases in NIDDM in many lower-income countries.[33,46,47] Other work indicates that many of the cardiovascular conditions related to NIDDM such as hypertension, dyslipidaemia and atherosclerosis are documented as increasing rapidly. The epidemiological prevalence data are spotty but indicate serious and high levels of these conditions, in particular NIDDM. NIDDM comprises 85 per cent or more of all diabetes cases. Recently, a most provocative cancer study has laid a strong basis for linking the diet, activity and body composition trends discussed above to the likelihood of increased rates of prevalence for a larger number of cancers.[48]

A related clinical and epidemiological literature highlights the importance of the same factors noted as being central to the nutrition transition – diet shifts, reduced physical activity and obesity – as also being critical determinants of NIDDM.[49–52] More recently this same literature has clarified the potential role for genetics and regional adiposity as they interact with these other factors.

Diet is the least understood determinant of NIDDM. A clear literature has shown that in terms of mechanisms and epidemiology, obesity and activity are closely linked to NIDDM. Several reviews lay out the case for these factors. Zimmet and his colleagues have been particularly earnest in exploring these issues at the population level in a number of lower-income and transitional societies.[51,52]

Some basic characteristics of NIDDM may provide a clear basis for linking key components of the nutrition transition – increases in obesity and reductions in activity – to the rapid increases in NIDDM in lower-income countries.

Obesity

It is clear that obesity, and more particularly upper-body regional distribution of the body fat, is a key parameter in the aetiology of NIDDM. A vast literature has shown significant direct obesity relationships with NIDDM and the animal literature backs up this relationship. The work on abdominal obesity and its effects is more recent, but appears to be promising in more precisely explaining the role that body composition plays. To the extent this abdominal obesity relationship holds, the metabolic programming hypothesis becomes that much more important in showing a link between foetal and infant nutritional insults and their relationship to adiposity in the upper body area. Law et al (see Barker[17]), in a follow-up study of British men, found abdominal fatness in adults to be associated with reduced foetal growth, manifested by low birthweight (LBW), and in particular LBW relative to placental weight. In a study of American white people and Hispanics, Valdez et al[53] found that the odds of expressing a syndrome consisting of dyslipidaemia, hypertension, unfavourable fat distribution and NIDDM were 1.72 times higher for the lowest compared to the middle third of birthweight.

In addition, there is a strong relative risk linking weight increases with diabetes. The odds of getting diabetes are considerable with a weight gain of 5–8kg for adults and they increase as weight gain goes up.[54]

Physical activity

It is understood that exercise affects insulin sensitivity such that heavy activity reduces the likelihood for a given level of obesity that a person will display the signs that allow him/her to be categorized as having NIDDM. In other words, physical activity lowers the serum insulin level or appears to do so. Zimmet reviews these relationships and notes other critical studies on this topic.[51,52]

Interactions of obesity and activity

Activity and obesity appear to interact but also to have separate effects. For example studies show that for each level of BMI or waist–hip ratio, there is an activity effect in terms of serum insulin level.

Genetic component

Zimmet and others who have focused on this issue as it relates to lower-income countries have felt that the highest genetic susceptibility was for Pacific Islanders, American-Indians, Mexican-Americans and other Hispanics, and Asian-Indians. Those with modest genetic susceptibility include Africans, Japanese and Chinese.[51,52] The age of onset of NIDDM is much lower for these populations and for a given level of obesity and waist–hip ratio it appears that the prevalence is higher. For instance, while the diagnosis is usually made after the age of 50 years, in these populations it is made much earlier.

Some of the articles that document the obesity increase, in particular those for Mauritius and the Pacific Islands and also for urban black South Africa also have shown a comparable rapid increase in the incidence of NIDDM and the biological precursors, higher glucose intolerance.[33,46,47]

O'Dea and colleagues[55] and also Galanis and colleagues[56] have explored the same issues in depth among Australian Aborigines and other South Pacific groups and have provided careful documentation of this linkage of the transition with NIDDM.

Evidence from dozens of smaller studies in China, the Western Pacific, South Africa, urban areas in many other countries, and other countries point clearly to an incipient major increase in cardiovascular disease in all of these countries.[47,57–59]

Discussion and Implications

The nutrition transition addresses a broad range of socioeconomic and demographic shifts that bring rapid changes in diet and physical activity levels to most regions of the world. The changes are occurring most rapidly as is shown by the shifts in the distribution of the population, income and occupation patterns. The diet changes, most specifically the shifts towards the higher fat and meat/reduced carbohydrate and fibre diet, is also a shift towards a more diverse and pleasurable diet. The activity patterns also represent a shift away from onerous, difficult labour-intensive activities. Thus, these dietary and physical activity shifts are desirable in many ways. Yet they carry with them many onerous nutritional and health effects. It is this paradox and complexity which makes it most difficult to understand ways to arrest the negative aspects of the nutrition transition. It is also clear that we must view the causes of obesity as environmental rather than personal or genetic.

We must be aware of the weak database on which this work relies. Documentation at the individual and household level of this transition exists in only a few countries. These countries, such as China, indicate a marked shift away from traditional coarse grains and towards refined grains and then towards meat, eggs and fats. They also indicate a strong propensity for increased income to be linked with increased dietary diversity and increased consumption of these higher fat 'Western diets'. Similarly they show marked changes in activity and obesity. Soon they will show the even more marked increases in CHD and NIDDM as others have shown in these countries. Yet, evidence for the shifts in physical activity is mainly indirect. The few studies that have monitored these trends have linked them to increased obesity but far more is needed in the way of research on this topic. This lack of research is a major gap, as are studies that collect both diet and activity data.

There is evidence that trends in obesity are not limited to one region, country or racial/ethnic group. The overall levels that are found in selected countries such as Mexico, South Africa, Malaysia, and nations of the Western Pacific are indicative of major public health problems. That these changes appear to be occurring across so many countries lends weight to the need to understand the underlying environmental causes related both to shifts in diet and activity rather than focusing attention solely on genetic causes of obesity. It also opens up the possibility that international studies can help to clarify the causes for these patterns.

It is likely that the rate of increase in obesity and NIDDM will increase rapidly, if the Barker metabolic programming hypothesis is correct. Stunting levels are very high in most lower-income countries. It is not unusual for 15–35 per cent of children to be stunted.[40] High rates of intrauterine growth retardation and LBW also exist. To the extent that fetal and infant insults, later combined with reduced activity and increased diet, lead to obesity and NIDDM, the African, Asian and Latin American regions might see rapid increases in the health complications associated with the nutrition transition.

The challenge is to devise ways to improve the lives of our citizens – that is to give people the more varied and tasty diets they want and less burdensome work – but also to prevent obesity, NIDDM, CHD and the other major diseases of civilizations. But we have few examples of countries that have been able to tackle these issues at the national level. Elsewhere I have summarized some of these issues. Milio has studied these trends most systematically.[60–62] The Scandinavian countries are unique in attempting to redirect their diets and health with prevention at the national level and they have done this with mixed success. Lower-income countries are only beginning to discuss and consider options for dealing with obesity. So long as poverty and hunger affect portions of the population, at the international and national level, the public and politicians are more likely to address that problem than they are to consider obesity. This means that not only are we trying to redirect popular changes in diet and activity, but we are also attempting to fight them during a time when public attention is focused on these problems of poverty and dietary deficit. Our solutions must not adversely affect the undernourished. At the same time we must begin to develop an array of large-scale options that national governments can implement. As with any other epidemic, we must focus much of our energy on environmental solutions.

Diet and Health: Diseases and Food

Tim Lang and Michael Heasman

Let Reason rule in man, and he dares not trespass against his fellow-creature, but will do as he would be done unto. For Reason tells him, is thy neighbour hungry and naked today, do thou feed him and clothe him, it may be thy case tomorrow, and then he will be ready to help thee.

Gerrard Winstanley, English Leveller, 1609–1676[1]

Core Arguments

The Productionist paradigm is critically flawed in respect of human health. Half a century ago it responded to issues then seen as critical but which now require radical revision. While successfully raising the caloric value of the world food supply, it has failed to address the issue of quality, and as a result, there is now a worldwide legacy of externalized ill health costs. The world's human health profile is now very mixed. Within the same populations, in both developed and developing countries, there exists diet-related disease due both to under- and over-consumption. The pattern of diet that 30 years ago was associated with the affluent West is increasingly appearing in the developing countries, in a phenomenon known as the 'nutrition transition': while the incidence of certain diet-related diseases has decreased, such as heart disease in the West, others are increasing, particularly diabetes and obesity worldwide, and heart disease in the developing world. Massive global inequities in income and expectations contribute to this double burden of disease, and current policies are failing to address it.

Introduction

One of the key Food Wars is over the impact of the modern diet on human health. In the last quarter of the 20th century, nutrition moved from the sidelines of public

Reprinted from Lang T and Heasman M. 2004. Diet and health: Diseases and food, in Lang T and Heasman M. *Food Wars*, Earthscan, London.

health to being central to the marketing of foodstuffs, and major public health campaigns urged consumers to improve their diets.

This human health dimension is central to our critique of the Productionist paradigm in two respects. First, even though global food production has increased to meet caloric needs, its nutritional content may be less than desirable. Second, food distribution remains deficient: nearly a billion people remain malnourished. In this chapter, we explore the relationship between diet and the range of disease and illnesses that are associated with food choices. We discuss, too, the existence of gross inequalities within and between countries in the form of food poverty amidst food abundance and wealth.

In late 2002 and 2003, a wave of new public health reports reminded the world that diet is a major factor in the causes of death and morbidity. Although deeply unpalatable to some sections of the food industry, these reports were sober reminders of the enormity and scale of the public health crisis. The joint WHO and FAO's 2003 report on diet, nutrition and the prevention of chronic diseases drew attention to high prevalence of diseases which could be prevented by better nutrition, including:[2]

- obesity;
- diabetes;
- cardiovascular diseases;
- cancers;
- osteoporosis and bone fractures;
- dental disease.

Of course, these diseases are not solely exacerbated by poor diet but also by lack of physical activity. In truth, this report was only reiterating the story of nutrition's impact on public health that had been rehearsed for many years, and the evidence for which was judged to be remarkably sound, but as Dr Gro-Harlem Brundtland, then the Director-General of the WHO, stated in the report: 'What is new is that we are laying down the foundation for a global policy response.' To this end, the WHO set up an international consultation dialogue to prepare its global strategy on diet, physical activity and health, scheduled to be launched in 2004. By international agency standards, this relatively speedy shift from evidence to policy making indicates the real urgency of the problem. The draft strategy was launched ahead of schedule in December 2003.[3]

Already by 2002, the WHO had produced a major review of the national burdens that such diseases cause. Of the top ten risk factors associated with non-communicable diseases, food and drink contribute to eight (with the two remaining – tobacco and unsafe sex – not associated with diet and food intake):[4]

- blood pressure;
- cholesterol;
- underweight;

- fruit and vegetable intake;
- high body mass index;
- physical inactivity;
- alcohol;
- unsafe water, sanitation and hygiene.

In the 2003 World Cancer Report, the most comprehensive global examination of the disease to date, the WHO stated that cancer rates could further increase by 50 per cent to 15 million new cases in 2020.[5] To stem the rise of this toll, the WHO and the International Agency for Research on Cancer (the IARC) argued that three issues in particular need to be tackled:

- Tobacco consumption (still the most important immediate avoidable risk to health).
- Healthy life-style and diet, in particular the frequent consumption of fruit and vegetables and the taking of physical activity; early detection and screening of diseases to allow prevention and cure.

In addition to these UN reports, the International Association for the Study of Obesity (the IASO) revised its figures of the global obesity pandemic: it estimates that 1.7 billion people are overweight or obese, a 50 per cent increase on previous estimates. The IASO's International Obesity Task Force stated that the revised figures meant that most governments were simply ignoring one of the biggest risks to world population health.[6]

These reports testify to an extensive body of research and evidence from diverse sources around the world of the link between food availability, consumption styles and specific patterns of disease and illness. Table 13.1 confirms some of the diet-related causes of death throughout the world. Good health and longevity were intended to result from ensured sufficiency of supply; at the beginning of the 21st century, far from diet-related ill health being banished from the policy agenda, it appears to be experiencing a renewed crisis.

Under the old Productionist paradigm, the main focus was under-nutrition. Yet at the end of the 20th century, with diseases such as heart disease, cancers, diabetes and obesity rampant worldwide, not just in the affluent West, a new focus must be placed on diet and inappropriate eating. In this chapter, we begin to explore wider societal changes which impose progress in this regard through demographic shifts, maldistribution of and poor access to food, and spiralling health-care costs. These factors add weight to our argument that the Productionist paradigm is beyond its own sell-by date.

Policy making is failing to address the causes of these food-related health problems and too often resorts to only palliative measures. This is partly because the Productionist paradigm's approach to health narrows the framework for considering alternative solutions: by being centred on striving to increase output, it has taken only a medicalized, rather than a socially determined, view of health.

Table 13.1 *Some major diet-related diseases*

Problem	*Extent/comment*
Low birthweights	30 million infants born in developing countries each year with low birthweight: by 2000, 11.9 per cent of all newborns in developing countries (11.7 million infants)
Child under-nutrition	150 million underweight preschool children: in 2000, 32.5 per cent of children under 5 years in developing countries stunted, amounting to 182 million preschool children. Problem linked to mental impairment. Vitamin A deficiency affects 140–250 million schoolchildren; in 1995, 11.6 million deaths among children under 5 years old in developing countries
Anaemia	Prevalent in schoolchildren; maternal anaemia pandemic in some countries
Adult chronic diseases	These include adult-onset diabetes, heart disease and hypertension, all accentuated by early childhood under-nutrition
Obesity	A risk factor for some chronic diseases (see above), especially adult-onset diabetes.[7] Overweight rising rapidly in all regions of the world
Underweight	In 2000, an estimated 26.7 per cent of preschool children in developing countries.
Infectious diseases	Still the world's major killers but incidence worsened by poor nutrition; particularly affects developing countries
Vitamin A deficiency	Severe vitamin A deficiency on the decline in all regions, but sub-clinical vitamin A deficiency still affects between 140 and 250 million preschool children in developing countries, and is associated with high rates of morbidity and mortality

Source: Adapted from ACC/SCN 2000[8]

Could the proponents of Productionism have anticipated the scale of these most recent health concerns? To some extent, they could not. Even excessive intake of fats as causing ill health might have been something of a shock for the Productionist paradigm, as it was almost heretical to argue that too much of a nutrient could be harmful to health.[9] Part of the problem here was the essential paternalism of the paradigm which assumed total knowledge of all variables needed to make good food policy: governments and companies could be trusted to look after the public health; the consumers' role was to select products to create their own balanced diets. Recent history, however, has shown that governments and the food supply chain failed to adapt to new scientific knowledge in relation to food and health. Nationally and internationally, the influence of health scientists on public policy has been minimal. Consumerism triumphed. To some extent, too, the public health world has colluded in its own marginalization from 'live' policy making by its fixation with deficiency diseases: for example, on programmes of food fortification or on protein shortages which could be made up by increased meat and dairy production. Despite a successful worldwide campaign to increase intake of folic acid following the discovery of its connection with spina bifida (neural tube defect syndrome), the overall impact of nutritional science in policy making has been negligible. Its response to the current epidemic of heart disease has been 'health education' – advice, leaflets and exhortations to change behaviour – explaining it as caused by modern life-styles, rather than by preventable dietary deficiencies. Almost as soon as the Productionist paradigm was put in place worldwide in the last half of the 20th century, global campaigns were needed to address the increase in degenerative diseases. However, the necessary policy instruments were not in place to tackle the health impact of long-term shifts in diet. The UN bodies which noted the evidence of new patterns of ill health were merely intergovernmental bodies who lacked any administrative power and influence to act on the global and national level. Commercial interests, on the other hand, had no such limits and could pursue their global ambitions, selling foods and a life-style around the world without regard to their consequences, and being able to defend their actions as being in the public interest.

Instead, the developed world now must confront one of the most challenging food and health disasters ever to face humankind: an epidemic of obesity with little prospect of an end in sight and the prospect of a new wave of diet-related diseases in its wake. It has little in its armoury with which to combat the causes of obesity, now affecting significant numbers of children and with even graver implications for future population health. Health education is ineffective; consumerism is part of the problem, but politically it is nearly sacrosanct.

Meanwhile, hunger and insufficiency continue, ironically, to prevail. As a 1995 FAO review of the global picture starkly put it: '[H]unger … persists in developing countries at a time when global food production has evolved to a stage when sufficient food is produced to meet the needs of every person on the planet.'[10] Over-consumption and under-consumption coexist. There is gross inequality of global distribution and availability of food energy. The same review asserted that Western Europe, for example, has in theory 3500 kilocalories (kcal) available per person per day and North America has 3600, while sub-Saharan Africa has 2100 and India has 2200. By 2015 the FAO calculates that 6 per cent of the world's population (462 million people) will be living in countries with under 2200kcal available per person. And by 2030, in the most optimistic scenario, in sub-Saharan Africa 15 per cent of the population will be undernourished. Numbers of the undernourished look set only to decline much more slowly than suggested by targets, for example those of the World Food Summit of 1996.[11]

The transnational nature of these patterns of diet-related disease demands public policy attention. The enormity of this human health problem cannot be overemphasized. Diseases associated with deficient diet account for 60 per cent of years of life lost in the established market economies.[12]

Scientists categorize diseases into two broad groups: communicable (carried from person to person or via some intermediary factor; these include diseases such as malaria, food poisoning, SARS); non-communicable (acquired by life-style or other mismatch between humans and their environment, such as cardiovascular disease and cancers). Table 13.2 indicates that in the developed world, deaths

Table 13.2 *Number of deaths by WHO regions, estimates for 2002 (thousands)*

through infectious and parasitic diseases are very low compared to developing countries, while diet-related non-communicable diseases like coronary heart disease and cancers are high in both developed and developing worlds. Degenerative disease rates are already high in the developing world. Figure 13.1 gives the leading causes of mortality by age to give another view of the global disease patterns.

The WHO and the FAO reports stress that world health in general is in transition with non-communicable diseases now taking a higher toll than communicable

diseases. Figure 13.2 shows the WHO prognosis of how the rates of non-communicable disease are expected to rise. Factors in this health transition include diet, demographic change (such as an ageing population) and cultural factors related to globalization.

The Nutrition Transition

In a series of papers, Professor Barry Popkin and his colleagues have argued that there is what they term a 'nutrition transition' occurring in the developing world, associated primarily with rising wealth.[13,14] The thesis, which has been extensively supported by country and regional studies,[15] argues simply that diet-related ill health previously associated with the affluent West is now becoming increasingly manifest in developing countries.[16,17] The 'nutrition transition' suggests shifts in diet from one pattern to another: for example, from a restricted diet to one that is high in saturated fat, sugar and refined foods, and low in fibre. This transition is associated with two other historic processes of change: the demographic and epidemiological transitions. Demographically, world populations have shifted from patterns of high fertility and high mortality to patterns of low fertility and low mortality. In the epidemiological transition, there is a shift from a pattern of disease characterized by infections, malnutrition and episodic famine to a pattern of disease with a high rate of the chronic and degenerative diseases. This change of disease pattern is associated with a shift from rural to urban and industrial life-style.

WHO researchers have noted that changes in dietary patterns can be driven not just by rising income and affluence but also by the immiseration that accompanies others' rising wealth;[18] low income countries are experiencing the effects of the transition but cannot afford to deal with them.[19] Popkin argues that, while the nutrition transition brings greater variety of foods to people who previously had narrow diets, the resulting health problems from the shift in diet should not be traded off against the culinary and experiential gains. Consumers might enjoy the new variety of foods that greater wealth offers but they are often unaware of the risk of disease that can follow. The implications of the nutrition transition now ought to exercise the minds of global as well national policy makers: certainly health policy specialists are concerned at the rise of degenerative diseases in low- and middle-income countries.[20,21]

Nutrition may have recently become a key notion in modern dietary thinking but it only echoes the insights of an earlier generation of researchers which included nutrition and public health pioneers such as Professors Trowell and Burkitt, whose observations from the 1950s to the 1980s led them to question 'whether Western influence in Africa, Asia, Central and South America and the Far East is unnecessarily imposing our diseases on other populations who are presently relatively free of them'.[22] Trowell and Burkitt, both with long medical experience in Africa, could easily explain the variation in infectious diseases, but not the variation in rates of non-infectious diseases such as heart disease between countries at different economic levels of wealth and development. In Africa in the post-World War II period, they witnessed the rise of key indicators for diseases such as heart disease and high blood pressure in peoples who had previously had little experience of them.[23] The dietary transition is swift. An FAC study of very undernourished Chinese people (living on 1480kcal per day) shows that they derive three-quarters of their energy intake from starchy staples such as rice, while better-fed Chinese (living on 2500kcal per day) are able to reduce their energy intake from such staples and to diversify their food sources (see Figures 13.3 and 13.4 which compare the diets of undernourished and well-nourished people in China).

Popkin has shown how this same process occurs in both urban and rural populations in developing countries with rising incomes. Figures 13.5 and 13.6 show

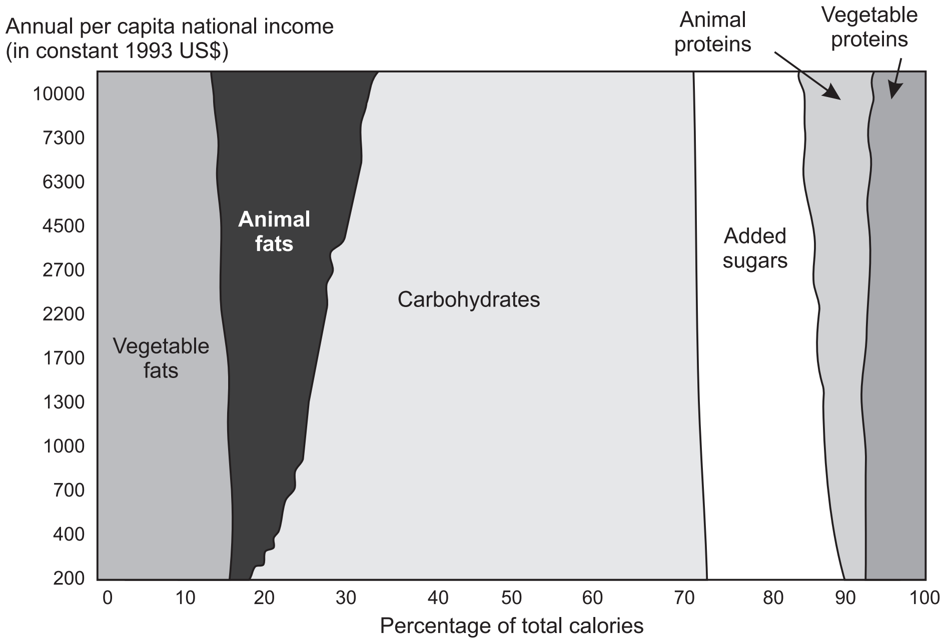
the relationship between per capita income and what predominantly rural and predominantly urban populations eat as both get wealthier:[24] both eat more meats and fats, and reduce carbohydrate, as a proportion of their overall diet. But there



Source: FAO/World Bank/Popkin, B (1998) 'The nutrition transition and its health implications on lower income countries', *Public Health Nutrition*, 1, 5–21

Figure 13.6 *Relationship between the proportion of energy from each food source and GNP per capita, with the proportion of the urban population at 75 per cent, 1990*

still remain differences between urban and rural populations, probably due to their different levels of activity, access to dietary ingredients and cultural mores.[25] The more urban population also consumes more added sugars as it gets wealthier, whereas the rural population consumes less. Popkin and his colleagues' point is that changing economic circumstances markedly shape the mix of nutrients in the diet and that life-style factors – such as the degree of urbanization[26] and changing labour patterns – have a major effect on health.

The transition is occurring in areas that usually receive little food policy attention. A study by the WHO has reported that in the Middle East changing diets and life-styles are now resulting in changing patterns of both mortality and morbidity there too.[27] Dietary and health changes can be rapid. In Saudi Arabia, for instance, meat consumption doubled and fat consumption tripled between the mid-1970s and the early 1990s; in Jordan, there has, in the same timescale, been a sharp rise in deaths from cardiovascular disease. These problems compound older Middle-Eastern health problems such as protein-energy malnutrition, especially among children. In China, the national health profile began to follow a more Western pattern of diet-related disease as the population gradually urbanized,[28] coinciding with an increase in degenerative diseases. Consumption of legumes such as soyabean was replaced by animal protein in the form of meat. One expert nutritional review of this problem concluded that exhorting the Chinese people to consume more soy when they were voting with their purses to eat more meat would be ineffective 'in the context of an increasingly free and global market'.[29] Such studies can suggest that the battle to prevent Western diseases in the developing world appears already to have been lost. If the nutrition transition is weakening health in China, the world's most populous and fastest economically growing nation, which has 22 per cent of the world's population but only 7 per cent of its land, what chance is there for diet-related health improvements throughout the developing world?

As populations become richer, they substitute cereal foods for higher-value protein foods such as milk, dairy products and meat, increased consumption of which is associated with Westernization of ill health. Relatively better-off populations also consume a greater number of non-staple foods and have a more varied, if not healthier, diet.[30] Thus we have the modern nutritional paradox: in the same low-income country there may be ill health caused by both malnutrition and over-nutrition; in the same rural area of a poor country both obesity and underweight can coexist.

In policy terms the challenge is whether India, China, Latin America or Africa, for example, can afford the technical fixes that the West can resort to in order to improve diet-related health:[31] coronary bypass operations; continuous drug regimes; expensive drugs and foods with presumed health-enhancing benefits;[32] and subscriptions to gyms and leisure centres. The affluent middle classes in the developed world might be able to afford such fixes but the vast numbers in the developing world certainly will not. Technical fixes are not societal solutions.

It could be argued that the increase in degenerative diseases is the inevitable down-side of economic progress. The problem for policy making is how to differentiate between protecting the already protective elements of traditional, indigenous diets such as legumes, fruit and vegetables, and opening up more varied food markets, which is deemed to be good economic policy. In practice, too few policy makers in the developing world have been prepared to fight to keep 'good' elements of national and local diets or to constrain the flow of Western-style foods and drinks into their countries lest they infringe support for trade liberalization. Thus, in stark terms, trade and economic policies have triumphed over health interests. US-style fast foods – the 'burgerization' of food cultures – have been hailed as modernity. We must now expose the production, marketing and prices of fast food,[34,35] their nutritional value and their impact on health.[36]

Three Categories of Malnutrition: Underfed, Overfed, and Badly Fed

More than 2 billion people in the world today have their lives blighted by nutritional inadequacy. On one hand, half of this number do not have enough to eat;

Table 13.3 *Types and effects of malnutrition*

Type of malnutrition	*Nutritional effect*	*No. of people affected globally (× billion)*
Hunger	deficiency of calories and protein	at least 1.2
Micronutrient deficiency	deficiency of vitamins and minerals	2.0–3.5
Over-consumption	excess of calories, often accompanied by deficiency of vitamins and minerals	at least 1.2–1.7

Source: Gardner and Halweil (2000), based on WHO, IFPRI, ACC/SCN data[33]

on the other hand, a growing army of people exhibit the symptoms of overfeeding and obesity. In both cases, the international communities are floundering for solutions, and malnutrition results, as indicated by Table 13.3.

Figure 13.7 highlights the role of the mother in infant health. Even before conception, the mother's own nutrition is vital.[37] It is now understood that children who are born with a low birthweight are at increased risk of developing heart disease and that good nourishment of the foetus is key. That nutrition affects disease patterns and life expectancy is now well documented.[38]

Figure 13.8 *Number of undernourished by region, 1996–1998 (millions)*

One of the particularly tragic consequences of undernourishment is its impact on the worlds children. UNICEF calculates that 800 million children worldwide suffer malnutrition at any given time (Figure 13.8 gives the FAO's estimated locations of these millions. Table 13.4 then gives the sobering projections for 2015 and 2030.) High proportions of Asian and African mothers are undernourished, largely due to seasonal food shortages, especially in Africa. About 243 million adults in developing countries are deemed to be severely undernourished.[39] This type of adult under-nutrition can impair work capacity and lower resistance to infection.

Against a rapid growth in world population, well-informed observers agree that greater food production is needed for the future.[40–43] One estimate suggests that by 2020 there will be 1 billion young people growing up with impaired mental

Table 13.4 *Projected trends in undernourishment by region, 1996–2030*

Source: FAO (2000) *Agriculture: Towards* 2015/30, Technical Interim Report, April, Rome, FAO, www.fao.org development due to poor nutrition. At a conservative estimate, this means there will be 40 million young people added to the total each year.[44]

The Obesity Epidemic

As early as 1948, there were medical international groups researching the incidence of obesity in various countries.[45] There were official reports at country level by the early 1980s,[46] and there has also been a commercial and consumer response to obesity for even longer.[47] But the grip of international obesity was in fact confirmed by the WHO's Task Force on Obesity in 1998. Today, overweight and obesity are key risk factors for chronic and non-communicable diseases.[48] In developing countries obesity is more common amongst people of higher socioeconomic status and in those living in urban communities. In more affluent countries, it is associated with lower socioeconomic status, especially amongst women and rural communities.[49] Historically and biologically, weight gain and fat storage have been indicators of health and prosperity. Only the rich could afford to get fat. By 2000, the WHO was expressing alarm that more than 300 million people were defined as obese, with 750 million overweight, i.e. pre-obese: over a billion people deemed overweight or obese globally.[50] But by 2003, this figure had been radically revised upwards when the IASO calculated that up to 1.7 billion people were now overweight or obese. The new figures were in part due to more accurate statistics but also to the recalculation of obesity benchmarks, which acknowledged rising obesity in Asia.[51]

Particularly worrying is that extreme degrees of obesity are rising even faster than the overall epidemic: in 2003, 6.3 per cent of US women, that is 1 in 16, were morbidly obese, with a body mass index of 40 or more.

Obesity is defined as an excessively high amount of body fat or adipose tissue in relation to lean body mass. Standards can be determined in several ways, notably by calculating population averages or by a mathematical formula known as 'body mass index' (BMI),[52] a simple index of weight-for-height: a person's weight (in kilos) divided by the square of the height in metres (kg/m^2). BMI provides, in the words of the WHO, 'the most useful, albeit crude, population-level measure of obesity'. A personal BMI of between 25 and 29.9 is considered overweight; 'obesity' means a BMI of 30 and above; a personal BMI of less than 17 is considered underweight. There is some argument about whether the definition of overweight (a BMI within the 25–29.9 range) should be lowered from 25 to 23, in which case tens of millions more people would be considered overweight, and such an unofficial reclassification has led to the disparity between current world obesity figures.

BMI levels are a useful predictor of risk from degenerative diseases. Unutilized food energy is stored as fat. Currently, the US National Institutes of Health consider that all adults (aged 18 years or older) who have a BMI of 25 or more are at risk from premature death and disability as a consequence of overweight and obesity.[53] Men are at risk who have a waist measurement greater than 40 inches (102cm); women are at risk who have a waist measurement greater than 35 inches (88cm). Whilst height is obviously also taken into consideration, we should regard these measurements as key health benchmarks.

Figure 13.9 shows how, in a remarkably short time, the rate of obesity within countries is rising. In the UK, for instance, between 1980 and 2000, obesity trebled from 7 per cent of the population to 21 per cent.[54] Particularly alarming is that the 'North Americanization' of obesity is spreading down Latin America.[55] Figure 13.10 illustrates the level of obesity in comparison to underweight in developed and developing countries. In many countries, levels of obesity are double what they were 15 years ago.[56] In Peru, Tunisia, Colombia, Brazil, Costa Rica, Cuba, Chile, Mexico and Ghana, for example, overweight adults outnumber those who are thin. Even Ethiopia and India, traditionally beset by under-nutrition[57] and starvation now have the added burden of an emerging obesity problem. The trend to obesity is occurring in countries with different economic profiles, from the Asian 'Tiger' economies to the oil-rich Middle East.[58]

Rising obesity rates among children are particularly troubling to health professionals, as this trend suggests massive problems of degenerative disease for the future. In Jamaica and Chile, for instance, one in ten children is obese; in Japan, a country historically with a very low incidence of fat in its diet and with a low incidence of

obesity, the frequency of obesity in schoolchildren has increased from 5 per cent to 9 per cent for girls and 10 per cent for boys in 1996.[59] (Table 13.5 summarizes the rapid rise in obesity as measured by comparing initial surveys with follow-up worldwide studies. The final column of the table shows how obesity is becoming out of control in developed and developing countries alike.) Even in Australia, obesity rose 3.4-fold for boys and 4.6-fold for girls between 1985 and 1995; in Egypt, 3.9-fold between 1978 and 1996; in Morocco, 2.5-fold in just five years, from 1987 to 1992; in Scotland by 2.3-fold for boys and 1.8-fold for girls between 1984 and 1994. A child's weight can be thrown off balance by a daily consumption of only one sugar-sweetened soft drink of 120kcals; over ten years, this intake would turn into 50kg of excess growth. Although their review also fully acknowledged the role of genetics, the authors pointed to pressures on children's diets from advertisements to help explain the rapidity of consumption and obesity changes.[60]

Health education seems to be powerless before this rising tide of obesity. On the island of Mauritius, for instance, a study which examined adults over a period of five years found that, despite a national programme promoting healthy eating and increased physical activity, obesity levels had increased dramatically:[61] men with a BMI above 25 increased from 26.1 per cent to 35.7 per cent and for women the figure grew from 37.9 per cent to 47.7 per cent during the five-year study. The government of Mauritius concluded that a National Nutrition Policy and National Plan of Action on Nutrition was needed.[62] Even in the US, the homeland of fast food, President George W. Bush was so alarmed by the obesity crisis that in 2002 he launched a national debate. He has long had good reason for concern,[63] as even as far back as 1986, the economic costs of illness associated with overweight in the US were estimated to be $39 billion; today the estimated cost of obesity and overweight is about $117 billion.[64] The rise in US obesity is dramatic: between 1991 and 2001, adult obesity increased by 74 per cent. The percentage of US children and adolescents who are defined as overweight has more than doubled since the early 1970s, and about 13 per cent of children and adolescents are now seriously overweight.[65] These general US figures disguise marked differences between ethnic groups and income levels: according to the Centers for Disease Control and Prevention, 27 per cent of black and about 21 per cent of Hispanics of all ages are considered obese – that is, a third overweight – compared with a still worrying but lower 17 per cent among whites.[66] The poor are more obese than the more affluent within the US. The price of food is a key driver of obesity: saturated fats from dairy and meat and hydrogenated (trans) fats are relatively cheap.[67]

The connection between overweight and health risk is alarmingly highlighted by the following list of the physical ailments that an overweight population (with a BMI higher than 25) is at risk of:[68]

- high blood pressure, hypertension;
- high blood cholesterol, dyslipidemia;
- type-II (non-insulin-dependent) diabetes;
- insulin resistance, glucose intolerance;
- hyperinsulinaemia;
- coronary heart disease;
- angina pectoris;
- congestive heart failure;
- stroke;
- gallstones;
- cholescystitis and cholelithiasis;
- gout;
- osteoarthritis;
- obstructive sleep apnea and respiratory problems;
- some types of cancer (such as endometrial, breast, prostate and colon);
- complications of pregnancy;
- poor female reproductive health (such as menstrual irregularities, infertility and irregular ovulation);
- bladder control problems (such as stress incontinence);
- uric acid nephrolithiasis;
- psychological disorders (such as depression, eating disorders, distorted body image and low self-esteem).

There is a vocal position – particularly articulated in the US – arguing that the critique of obesity is an infringement of personal liberty and 'size-ist', making cultural value statements. If someone wants to be fat and is content and loved by others, goes this argument, what does it matter? The list of health problems given

Table 13.5 *Global increases in the prevalence of childhood obesity*[a]

(2001) Obesity prevalence and trends in Latin American countries, *Obesity Review*, vol 2, pp99–106 above is surely an answer to this position. The costs of what is presented as an 'individual' problem are, in fact, society wide. The ill health that results is paid for either in direct costs or in a societal drag – lost opportunities, inequalities and lost efficiencies. This is why policy makers have to get to grips with obesity and the world's weight problem.

Both obesity and overweight are preventable. At present the debate about obesity is divided about which of three broad strategies of action is the best to address. One strand argues that it is a problem caused by over-consumption (diet and the types of food) and oversupply; another that it is lack of physical activity; and the third that there might be a matter of genetic predisposition. Certainly, the emphasis has to be on changing the environmental determinants that allow obesity to happen. A pioneering analysis by Australian researchers in the mid-1990s proposed that the obesity pandemic could only be explained in 'ecological' terms: Professors Garry Egger and Boyd Swinburn set out environmental determinants such as transport, pricing and supply; they claimed that environmental factors were so powerful in upsetting energy balances that obesity could be viewed as 'a normal response to an abnormal environment'.[69] So finely balanced are caloric intake and physical activity than even slight alterations in their levels can lead to weight gain. Swinburn and Egger assert that no amount of individual exhortation will reduce worldwide obesity;[70,71] transport, neighbourhood layout, home environments, fiscal policies and other alterations of supply chains must be tackled instead.

Calculating the Burden of Diet-related Disease

During the 1990s, world attention was given to calculating the costs of what has been called the 'burden of disease'. Five of the ten leading causes of death in the world's most economically advanced country, the US, were, by the 1980s, diet-related: coronary heart disease, some types of cancer, stroke, diabetes mellitus and atherosclerosis. Another three – cirrhosis of the liver, accidents and suicides – were associated with excessive alcohol intake.[72] Together these diseases were accounting for nearly 1.5 million of the 2.1 million annual deaths in the US. Only two categories in the top ten – chronic obstructive lung disease and pneumonia and influenza – had no food connection.

In a 1990s study published by the World Bank, *The Global Burden of Disease*,[73] the authors Murray and Lopez gave a detailed review of causes of mortality in eight regions of the world. Ischaemic heart disease accounted for 6.26 million deaths. Of these, 2.7 million were in established market economies and formerly socialist economies of Europe; 3.6 million were in developing countries (out of 50.5 million deaths from all causes in 1990). Stroke was the next most common cause of death (4.38 million deaths, almost 3 million in developing countries), closely followed by acute respiratory infections (4.3 million, 3.9 million in developing countries). Other leading causes of death include diarrhoeal disease (almost totally occurring in developing countries), chronic obstructive pulmonary disease, tuberculosis, measles, low birthweight, road-traffic accidents and lung cancer, with only diarrhoea and low birthweight having a diet-related aetiology. They also calculated that cancers caused about 6 million deaths in 1990. About 2.4 million cancer deaths occurred in established market economies and former socialist economies of Europe. By 1990, therefore, there were already 50 per cent more cancer deaths in less developed countries than in developed countries.

For their analysis, Murray and Lopez created a new index they called the DALY, standing for the 'disability adjusted life year'. A DALY is the sum of life years lost owing to premature death, and years lived with disability (adjusted for severity). It is thus a measure of both death and disability (both mortality and morbidity). The top ten DALYs in all developing regions combined already included ischaemic heart disease and cerebovascular disease. Murray and Lopez's report concluded: 'Clearly, the focus of research and debate about health policy in developing regions should address the current challenges presented by the epidemiological transition now, rather than several decades hence.' Table 13.6 gives their original breakdown for the world of the DALYs by main disease, present and anticipated.

The authors anticipated that the greatest increase in cardiovascular disease-related DALYs would occur in developing countries, up from 8.3 per cent in 1990 to 13.8 per cent in 2020 – a rising burden of disease for those countries which could least afford it. The corresponding increase in developed countries' DALYs associated with non-communicable diseases was calculated to be only relatively slight, rising from 20.4 per cent to 22.0 per cent. (The developed world already had a high base rate of DALYs from diet-related disease.) (Interestingly, there is hardly any movement

Table 13.6 *DALYs lost by cause for the developed and developing countries, 1990 and 2020*

in diabetes figures for developing countries and a fall for developed countries, yet it should be noted that diabetes figures are in fact rising rapidly worldwide. The newness of this diet-related epidemic might have been too late for Murray and Lopez's 1990 data.)

One purpose of the DALY method is to enable policy makers to estimate the relative risk of major factors for health. Table 13.7 gives the Swedish National Institute of Public Health's summary of the calculated impacts of smoking, alcohol, diet and physical activity for key DALYs in the EU and Australia. Again, the diet-related disease toll is very high. Smoking, as was noted at the start of this chapter, is a major contributory factor in heart disease but the dietary factors, when separated, were almost as great.

The DALY approach was extended in the 'World Health Report 2002' which was based on a series of massive multi-country studies designed to test and refine the methodology. Figure 13.11 details risk factors by level of development. The results, however, merely deepened the insights from the earlier study. If anything, the burden of diet-related disease and of lack of physical activity received even higher profile. Special studies on the impact of lack of fruit and vegetables in the diet showed great impact. The WHO–FAO 2003 report underlined how a variety of diseases, from heart disease to diabetes, were all associated with the same dietary pattern: over-consumption, excess fat, under-consumption of fruit and vegetables and excess added sugar and salt.[75]

The Financial Costs

In 2001, the Commission on Macroeconomics and Health, created by the WHO, argued that there were mutual benefits to be had from improved health and for the economy, particularly for those in low-income countries.[76] Table 13.8 shows how general health care costs are rising rapidly in many developed economies; in the developing world, the costs of health care for degenerative diseases are now also

looming as a serious concern. The growth of health expenditure is sometimes higher than the growth of gross domestic product (GDP). Table 13.9 gives a breakdown of the direct and indirect costs for a number of key diet-related diseases in the US; these costs are immense, even for such a rich society.

Health ministries, it appears, are locked in a model which tends to be curative rather than preventative. The UK health care system, for instance, costs £68 billion for around 60 million people, costs that are anticipated to rise to between £154 billion ($231 billion) and £184 billion ($276 billion) by 2022–2023 in 2002 prices.[78] In other words, at constant prices, UK health care costs are doubling.

In the context of diet-related disease, the direct and indirect financial tolls of ill health could offer opportunities for positive policy intervention through a health-enhancing food supply chain. An estimate for the UK by the Oxford University British Heart Foundation Health Promotion Research Group has calculated that coronary heart disease (CHD) – constituting about half of all cases of cardiovascular disease – costs the UK £10 billion per annum. These costs are made up of £1.6 billion in direct costs (primarily to the taxpayer through the costs of treatment by the NHS) and £8.4 billion in indirect costs to industry, and to society as a whole, through loss of productivity due to death and disability.[79] (This is probably an underestimate of the direct costs to the UK's National Health Service as these costs do not include the cancer treatment costs.)

A report chaired in 2002 by Derek Wanless, a former head of the NatWest Bank, for the Chancellor of the Exchequer produced not dissimilar calculations.[80]

It estimated that costs for the health service will rise alarmingly if targets are not met to reduce CHD and cancers. CHD treatment costs (drugs like statins and surgical techniques like revascularization) would add an additional £2.4 billion per annum by 2010–2011, doubling CHD expenditure. Such calculations remind us of the multi-headed nature of ill health. Smoking, diet, physical activity, genetics, environment and socioeconomic background all have direct health outcomes. Wanless and his team were convinced by US scientific work that high cholesterol – 'which is mainly due to diet' – accounts for 43 per cent of CHD incidence, compared to 20 per cent for smoking. This sort of evidence shows that the poor diet has such far-reaching financial implications that it warrants higher political attention. This case was confirmed by a second Wanless study arguing for the economic value of facing the public health costs of poor diet, life-style and education.[81] However, for the last quarter of a century policy attention has been directed to cutting costs, not by altering the food supply chain, but by such policies as contracting out services and by privatization. In the UK, less than £5 million a year is spent on food-related health education. Meanwhile, drug companies and surgeons only offer expensive but highly sophisticated solutions when the patient is already sick.

Indeed, drug treatments can be hugely expensive. A trial on over 20,000 UK people with high risks for heart disease showed that giving patients a type of drug known as statins reduced the risk of a first coronary attack by 25 per cent but would cost £1 ($1.5) per patient per day.[82] Currently, 1.8 million people are prescribed statins, costing UK£750 million a year. Taking statins for three years can reduce the risk of a heart attack by up to a third.

Coronary Heart Disease (CHD)

Since 1999, the WHO has attributed 30 per cent of all annual global deaths – that is, of 15 million people – to cardiovascular disease.[83,84] The majority of those deaths are in low- and middle-income countries. In 1998, 86 per cent of DALYs were lost to cardiovascular disease (CVD) worldwide.

The main risk factors for heart disease are high blood pressure, smoking and lipid concentrations (cholesterol levels). Others include age, sex, family history and the presence of diabetes. WHO recommendations for reducing CVD include:[85]

- regular physical activity;
- linoleic acid;
- fish and fish oils;
- vegetables and fruits, including berries;
- potassium;
- low to moderate alcohol intake.

The WHO judges that there is convincing evidence for the increasing risks from:

- myristic and palmitic acid;
- trans-fatty acids;
- high sodium intake;
- overweight;
- high alcohol intake.

In regard to CHD, public health policy has tended to focus on two things: health education as prevention, and improved medical treatment through drug, hospital and surgical care. It has also urged behavioural change, in particular a reduction of total fat intake and especially of saturated fats (mainly from animal meat and dairy fats). This health promotion policy has had an effect: rates of heart disease are declining in most affluent Western countries, after years of steady increase since the immediate post-World War II period (see Tables 13.10 and 13.11).[86]

The global picture is more complex, however.[87] For example, the steep rise in CHD in the newly independent countries of Eastern Europe (such as Belarus, Azerbaijan and Hungary) is worrying. Leaving the strictures of the Soviet era means only that already high rates of CHD have risen further. Even in countries considered to have a healthy diet, like Greece and Japan, social change is being accompanied by changing patterns of diet-related disease: Greece's CHD and obesity rates are rising as it changes to a more Northern European diet high in animal fats, following entry to the EU and increased tourism. Death rates from CHD may have dropped in the US and Finland, but it should be remembered that their morbidity and costs are still high, as was shown by the Global Burden of Disease studies.

This complexity keeps epidemiologists busy around the world, but the rapidity of change should bring little surprise. In 1981 Trowell summarized the emergence of CHD amongst East Africans: in the 1930s, he reported, autopsies had shown zero CHD in East Africa, and only one case among 2994 autopsies conducted in Makere University Medical School over the period 1931–1946. However, by the 1960s CHD in this region was emerging as a major rather than peripheral health problem.[88]

In China, between 1991 and 1995,[89] CHD accounted for 15 per cent of all deaths. Cholesterol levels here, compared to those found in Western populations, were low but were increasing rapidly among the urban populations where a more affluent lifestyle was being adopted. Daily intake of meat, eggs and cooking oil had increased while intake of legumes and cereals had decreased. A reduction in the consumption of Western fast foods was also recommended as were increasing physical activity levels, an urging which could be applied to many urbanizing developing countries.

Food-related Cancers

Since the 1980s, dietary factors have been thought to account for around 30 per cent of cancers in Western countries, making diet second only to tobacco as a preventable cause of cancer;[90] in developing countries diet accounted for around 20 per cent.[91] Table 13.12 gives the 1997 review of food-cancer research by the World Cancer Research Fund. An updated report is due out in 2006.

Table 13.12 *Cancers preventable by dietary means*

Notes: Included as 'dietary factors' in this table are various foods, nutrients, alcoholic drinks, body weight and physical activity. The panel has estimated the extent to which specific cancers or cancer in general are preventable by the dietary and associated factors described in this report. The figures suggested are ranges consistent with current scientific knowledge, and take established non-dietary risk factors, notably the use of tobacco, specific infections and occupational exposures to carcinogens, into account. The arrows represent either decreasing risk (↓) or increasing risk (↑).
Figures on global ranking and incidence: Parkin et al (1993); WHO (1997).
A mouth and pharynx; also chewing tobacco; b nasopharynx; c reliable worldwide data are not collected by IARC for this site; d conservative estimate based on the IARC (1993).

The annual WHO World Health Report has shown that cancers are increasing worldwide,[92] and the 2003 World Cancer Report suggested that, like obesity, rising cancer rates are preventable. By virtue of steadily ageing populations, cancer could further increase by 50 per cent to 15 million new cases a year by 2020. In 2000, 6.2 million people died of cancer worldwide (12.5 per cent of all deaths), but 22.4 million were living with cancer. In the South, cancers of the oesophagus, liver and cervix are more common, while in the North, there is a predominance of cancers of the lung, colon, pancreas and breast.

The most significant cause of death among men is lung cancer and among women breast cancer, but certain life-style changes, such as to diet or smoking habits, would alter these patterns. Some cancers are closely associated with diets centred on well-cooked red meats, animal proteins and saturated fats in large quantities, with a daily routine that takes in little physical activity.[93] Indeed, many cancers could be prevented by modifying dietary habits to include more fruits, vegetables, high-fibre cereals, fats and oils derived from vegetables, nuts, seeds and fish, and by limiting the intake of animal fats derived from meat, milk and dairy products.[94,95] A number of published studies show that an increase in antioxidant nutrients such as beta-carotene, vitamins C and E, zinc and selenium could also decrease the risk of certain cancers and there seems to be strong evidence that eating a diet rich in fresh fruit and vegetables will reduce the risk of stomach cancer.[96] Yet the nutrition transition is being driven in a different direction – towards a diet actually higher in processed foods and animal fats, key food industries within the Productionist paradigm.

Diabetes

The incidence of type II diabetes is, alarmingly, on the increase. This form of diabetes was formerly known as non-insulin-dependent diabetes mellitus, occurring when the body is unable to respond to the insulin produced by the pancreas; it accounts for around 90 per cent of cases worldwide. In Type I diabetes (formerly known as insulin-dependent), the pancreas fails to produce the insulin which is essential for survival; this form develops most frequently in children and adolescents, but is now being increasingly noted later in life.[97] It is anticipated that cases of type II diabetes will rise coming years (see Table 13.13): the WHO anticipates a doubling in the number of cases from 150 million in 1997 to 300 million in 2025, with the greatest number of new cases being in China and India.[98]

Diabetes is the fourth main cause of death in most developed countries. Research demonstrates the association between excessive weight gain, central adiposity (fat around the waist) and the development of type II diabetes. Diabetics are two to four times more likely to develop cardiovascular diseases than others, and a stroke is twice as common in people with diabetes and high blood pressure as it is for those with high blood pressure alone. In 2000, India recorded 32.7 million diabetics, China

Table 13.13 *Prevalence of diabetes worldwide*

	2000	*2030*	*Projected growth*
Africa	7020,553	18,244,638	160
Mediterranean	15,189,760	43,483,842	186

Western Pacific	36,138,079	71,685,158	98
Total	171,000,000	366,000,000	114

Source: WHO (2004) *Diabetes Action Programme*. Geneva, World Health Organization, available at www.who.int/diabetes/facts/worid_figures/en/

22.6 million and the US 15.3 million, while Brazil recorded only 3.3 million and Italy 3.1 million. In 2000, the five countries with the highest diabetes prevalence in the adult population only were Papua New Guinea (15.5 per cent), Mauritius (15 per cent), Bahrain (14.8 per cent), Mexico (14.2 per cent) and Trinidad & Tobago (14.1 per cent).[99,100] Such disparate statistics reflect a transition from traditional diet and from an activity-based life-style to a more sedentary one. By 2025, the prevalence of diabetes is anticipated to triple in Africa, the Eastern Mediterranean, the Middle East and South Asia. It is expected to double in the Americas and the Western Pacific and to almost double in Europe. In India, incidence is much higher in urban than rural populations:[101] in urban Chennai (Madras), for example, cases of diabetes rose by 40 per cent in 1988–1994. Incidence is rising among male urban dwellers of South India compared to the rural male population. In addition to diabetes mellitus, the prevalence of NIDDM increased dramatically within the urban populations of India within just a decade.[102] In Thailand, also, NIDDM is more pronounced amongst females in the urban population than it is in the rural population,[103] whilst in the rural environment, incidence of NIDDM amongst males is higher.

In the UK, Professor David Barker and colleagues have shown that adult diabetes is associated with low birthweight,[104] while studies in India suggest that poor interuterine growth, combined with obesity later in life is associated with insulin resistance, diabetes and increased cardiovascular risk.[105] Once again, a single disease seems attributable to a pattern of poor nutrition related to the life cycle, and is one whose costs are externalized onto society as a whole and health care in particular. Devastating complications of diabetes, such as blindness, kidney failure and heart disease, are imposing a huge financial burden: in some countries 5–10 per cent of national health budgets.

Food Safety and Foodborne Diseases

Whilst attention to such non-communicable diseases is of vital importance, food safety, foodborne diseases and other communicable diseases remain uppermost within food and public health policy, partly due to consumer campaigns about risks and to heightened media awareness of poor food processing standards. Food safety problems include risks from:[106]

- veterinary drug and pesticide residues;
- food additives;
- pathogens (i.e. illness-causing bacteria, viruses, parasites, fungi and their toxins);
- environmental toxins such as heavy metals (e.g. lead and mercury);
- persistent organic pollutants such as dioxins;
- unconventional agents such as prions associated with BSE.

In particular, companies have had to respond to new public awareness about food safety issues, and new regimes of traceability have been implemented to enable companies to track food ingredients in order to eliminate subsequent legal or insurance liability consequences. In this respect, food companies are anxious to present themselves as guardians of the public health.[107] The attention food safety receives is predictably higher in affluent countries when, on the evidence, the burden of ill health is far greater in the developing world, due to lack of investment and infrastructure, including drains, housing, water supplies and food control systems. The World Health Report 2002 pointed out that, in developing countries, water supply and general sanitation remain the fourth highest health-risk factor, after underweight, unsafe sex and blood pressure.[108] In developing countries which are building their food export markets, there is too often a bipolar structure, with higher standards for foods for export to affluent countries than for domestic markets. There ought to be a cascading down into internal markets of these higher standards.[109]

Environmental risks to health are a significant problem on the global scale and, in Western countries in the 1990s, new strains of deadly bacteria such as *E. coli 0157* captured policy attention, an estimated 30 per cent of people having suffered a bout of foodborne disease annually. The US, for instance, reports an annual 76 million cases, resulting in 325,000 hospitalizations and 5000 deaths.[110] The WHO estimates that 2.1 million children die every year from the diarrhoeal diseases caused by contaminated water and food,[111,112] asserting that each year worldwide there are 'thousands of millions' of cases of foodborne disease.[113]

In early industrializing countries, a grand era of engineering made dramatic health improvements in public health. Part of that investment included the introduction of effective monitoring and hygiene practice systems, such as the establishment of local authority laboratories and training, the packaging of foods and processes such as milk pasteurization. Today, public health proponents are actively trying to promote a 'second wave' of food safety intervention but this time using a risk-reduction management system known as Hazards Analysis Critical Control Point (HACCP), an approach designed to build safety awareness and control of potential points of hygiene breakdown into food handling and management systems. HACCP also encourages the creation of a 'paper' trail to enable tracking along the production process, essential in order to obviate errors and enable learning. Breakdowns in food safety have in the past led to major political and business crises, with governments under attack and new bodies responsible for food safety being set up in many countries. As food supply chains become more complex and as the scale of production, distribution and mass catering increases, so the chances for problems associated with food contamination rise; mass production breakdowns in food safety spread contamination and pathogens widely. An outbreak of *Salmonellosis* in the US in 1994, for example, affected an estimated 224,000 people.[114] *Listeria monocytogenes* has a fatality rate of 30 per cent, a fact that seriously dented UK public confidence in the 'cook-chill' and 'oven-ready' foods of the late 1980s.

Cross-border trade in agricultural and food products, as well as international pacts have brought food safely to the fore.[115] The Director-General of the WHO, in a speech on food safety to the UN Codex Alimentarius Commission, said: 'globalisation of the world's food supply also means globalisation of public health concerns'.[116] Crises over BSE, *Salmonellosis* and *E. coli*. for example, had had a significant political impact throughout both the UK and EU, for instance,[117] and many countries have experienced a fast rise in incidences of *Salmonellosis* and *Campylobacter* infections since the 1980s, both bacteria being associated with meat and meat products. Despite countries such as Denmark and Sweden having strict policies governing the extermination of flocks and herds found to be carrying *Salmonella*, the incidence continues through the contamination of feedstuffs, and in Denmark in 1998 the percentage of positive flocks with *Campylobacter* was 47.1 per cent.

Thus, in many developed countries with good monitoring systems, the incidence of foodborne disease has in fact risen during the era of the Productionist paradigm: in West Germany cases of infectious *S. enteritis* rose from 11 per 100,000 head of population in 1963 to 193 per 100,000 in 1990;[118] in England and Wales formal notifications of the same disease rose from 14,253 cases in 1982 to 86,528 in 2000. These cases resulted in millions of days lost from work but, fortunately, relatively few deaths.

Bacteria fill gaps left by nature, evolving new strains; but they are constantly evolving even as science combats existing strains. The new food processes and systems of distribution ushered in by the food technology revolution of the second half of the 20th century provided many opportunities for bacteria to develop and colonize new niches. The incidence of *Salmonella* in the UK, for example, first rose, and then, following good monitoring, hygiene intervention and political pressure, fell right back – in two decades.

Table 13.14 gives a list from the WHO of some of the pathogenic organisms that are associated with food and food hygiene: viruses, bacteria, trematodes

Table 13.14 *Some pathogenic organisms associated with public health, which may be transmitted through food*

Bacteria	*Protozoa*
Bacillus cereus	*Cryptosporidium* spp
Brucella spp	*Entamoeba histolyica*
Campylobacter jejuni and *coli*	*Giardia lamblia*
Clostridium botulinum	*Toxoplasma gondii*
Clostridium perfringens	
Escherichia coli (pathogenic strains)	**Trematodes** (flukeworms)
Listeria monocytogenes	*Fascioia hepatica*
Mycobacterium bovis	*Opistorchis felineus*
Salmonella typhi and *paratyphi*	
Salmonella (non-typhi) spp	**Cestodes** (tapeworms)
Shigella spp	*Diphyllobotrium latum*
Staphylococcus aureus	*Echinococcus* spp
Vibrio cholerae	*Taenia solium* and *saginata*
Vibrio parahaemolyticus	
Vibrio fulnificus	**Nematodes** (roundworms)
Yersinia enterocolitica	*Anisakis* spp
	Ascaris lumbricoides
Viruses	*Trichinella spiralis*
Hepatitis A	*Trichuris trichiura*
Norwalk agents	
Poliovirus	
Rotavirus

(flukeworms), cestodes (tapeworms) and nematodes (roundworms), the last three all small worms that can be found either in soil, fish or meats. The first two are concerns in global food trade particularly. In the case of bacteria such as *Listeria monocytogenes*, only 657 cases were reported throughout the EU in 1998;[119] in the same period, deaths from cardiovascular disease in the EU totalled 1.5 million, 42 per cent of all deaths,[120] while, in 1990, diarrhoeal diseases accounted for 11,000 years of life (DALYs) lost out of a total of 22.7 million in Europe; in the same year, cardiovascular disease accounted for 7 million, diabetes for 371,000 and cancer of the colon and rectum for 593,000,[121] and five times as many years of life were lost due to drug addiction than to diarrhoeal diseases.

Despite a low health burden in the developed world, the financial costs of food poisoning can be significant. Estimates in the US suggest that the diseases caused by major pathogens cost up to $35 billion each year in medical costs and lost productivity.[122] Policy makers must be concerned about both foodborne illness and degenerative diseases, the latter of which do not as yet receive sufficient political attention.

Food Poverty in the Western World

Most public health concern about food poverty rightly centres on the developing world, but it is also important to recognize that the impact of food poverty is significant in the developed world. The new era of globalization has unleashed a reconfiguration of social divisions both between and within countries; these social divisions are particularly marked in societies such as the UK and the US which have pursued neoliberal economic policies. Indeed, one review of EU food and health policies estimated that food poverty was far higher in the UK than any other EU country,[123] where inequalities in income and health widened under the Conservative government of 1979–1997. The proportion of people earning less than half the average income grew[124] and the bottom tenth of society experienced a real, not just relative, decline in income and an increase in social health distinctions. This was the converse of the post-World War II years of Keynesian social democratic policies during which inequalities narrowed: lower UK socioeconomic groups now experience a greater incidence of premature and low birthweight babies, and of heart disease, stroke and some cancers in adults. Risk factors such as bottle-feeding, smoking, physical inactivity, obesity, hypertension, and poor diet were clustered in the lower socioeconomic groups[125] whose diet traditionally derives from cheap energy forms such as meat products, full-cream milk, fats, sugars, preserves, potatoes and cereals with little reliance on vegetables, fruit and wholemeal bread. Essential nutrients such as calcium, iron, magnesium, folate and vitamin C are more likely to be ingested by the higher socioeconomic groups:[126,127] their greater purchasing power creates a market for healthier foods such as skimmed milk, wholemeal bread, fruit and other low-fat options. Similarly, in the US, hunger has been a persistent cause of concern for decades and rising during the 1990s when the Census Bureau calculated that 11 million Americans lived in households which were 'food insecure' with a further 23 million living in households which were 'food insecure without hunger' (in other words at risk of hunger).[128] Other US surveys of the time estimated that at least 4 million children aged under 12 were hungry and an additional 9.6 million were at risk of hunger during at least one month of the year. Despite political criticisms of these surveys, further research suggested that even self-reported hunger, at least by adults, is a valid indication of low intakes of required nutrients. It should be noted that, ironically, the US spent over US$25 billion on federal and state programmes to provide extra food for its 25 million citizens in need of nutritional support.[129]

Implications for Policy

This chapter has sketched the bare bones of a highly complex global picture of diet-related health. Over the last half-century, epidemiologists have generated many facts, figures and arguments about the role of food in the creation and prevention of ill health, linking what humans eat with their patterns of disease. They raise a number of important questions: how much of a risk does poor diet pose? What proportion of the known incidence of key diseases like cancer, heart disease, diabetes and microbiological poisoning can be attributed to the food supply? What levels of certainty can be applied to the many studies that have been produced? Is diet a bigger factor than, say, tobacco or genetics? For policy makers, the uncomfortable fact is that the pattern of diet-related diseases summarized in this chapter appears to be closely associated with the Productionist paradigm. Whilst the paradigm had as its objective the need to produce enough to feed people, its harvest of ill health was mainly sown in the name of economic development. Yet the public health message is clear: if diet is inappropriate or inadequate, population ill health will follow. Diet is one of the most alterable factors in human health, but despite strong evidence for intervention, public policy has only implemented lesser measures such as labelling and health education while the supply chain remains legitimized to produce the ingredients of heart disease, cancer, obesity and their diet-related degenerative diseases.

In making these tough assertions, we are aware that to piece together all food research evidence is immensely complex: more research is always needed; scientific understanding inevitably advances and is refined along the way. But surely, there is enough evidence for action. Certainly there is no shortage of reports and studies with which to inform policy. Calling for more research ought not to be an excuse for policy inaction. Policy procrastination is merely poor political prioritization.

Policy attention needs to shift from the overwhelming focus, enshrined in the Productionist paradigm, on under-consumption and under-supply to a new focus on the relationship between the oversupply of certain foodstuffs, excessive marketing and malconsumption, and do so simultaneously within and between countries. Historically, there has been too much focus on public education as the main driver of health delivery; the diet and health messages, while welcome, have not always had the widespread or long-lasting effect that current data suggests is needed. While there have been reductions, for example, in coronary heart disease mortality rates in affluent societies, this is not universally true, and health education as framed in the West may not be universally appropriate. The food supply chain itself must be reframed and must target wider, more health-appropriate goals.

Even rich countries are struggling to provide and fund equitable solutions to problems caused by diet: drugs and surgery, designer health foods, scientific research and public health education. But for developing countries, the majority of humanity, who have even fewer resources and weaker health care infrastructure, the picture is even more desperate. At the heart of the food policy challenge is the need to reinforce the notion of entitlement to food. While the 1948 Universal Declaration of Human Rights asserted the right to food for health for all, even into the new millennium the call is still not being adequately met, and, for humanity's sake, it must now be pursued with more vigour.

Food Politics: How the Food Industry Influences Nutrition and Health

M. Nestle

Introduction: The Food Industry and 'Eat More'

This chapter is from a book about how the food industry influences what we eat and, therefore, our health. That diet affects health is beyond question. The food industry has given us a food supply so plentiful, so varied, so inexpensive and so devoid of dependence on geography or season that all but the very poorest of Americans can obtain enough energy and nutrients to meet biological needs. Indeed, the US food supply is so abundant that it contains enough to feed everyone in the country nearly twice over – even after exports are considered. The overly abundant food supply, combined with a society so affluent that most people can afford to buy more food than they need, sets the stage for competition. The food industry must compete fiercely for every dollar spent on food, and food companies expend extraordinary resources to develop and market products that will sell, regardless of their effect on nutritional status or waistlines. To satisfy stockholders, food companies must convince people to *eat more* of their products or to eat their products instead of those of competitors. They do so through advertising and public relations, of course, but also by working tirelessly to convince government officials, nutrition professionals and the media that their products promote health – or at least do no harm. Much of this work is a virtually invisible part of contemporary culture that attracts only occasional notice.

This book exposes the ways in which food companies use political processes – entirely conventional and nearly always legal – to obtain government and professional support for the sale of their products. Its twofold purpose is to illuminate the extent to which the food industry determines what people eat and to generate much wider discussion of the food industry's marketing methods and use of the political system.

Reprinted from Nestle M. 2002. *Food politics: How the Food Industry Influences Nutrition and Health*. University of California Press, Berkeley. Introductory Chapter, pp1–28.

In my 25 years as a nutrition educator, I have found that food industry practices are discussed only rarely. The reasons for this omission are not difficult to understand. Most of us believe that we choose foods for reasons of personal taste, convenience and cost; we deny that we can be manipulated by advertising or other marketing practices. Nutrition scientists and practitioners typically believe that food companies are genuinely interested in improving health. They think it makes sense to work with the industry to help people improve their diets, and most are outraged by suggestions that food industry sponsorship of research or programmes might influence what they do or say. Most food company officials maintain that any food product can be included in a balanced, varied and moderate diet; they say that their companies are helping to promote good health when they fund the activities of nutrition professionals. Most officials of federal agriculture and health agencies understand that their units are headed by political appointees whose concerns reflect those of the political party in power and whose actions must be acceptable to Congress. Members of Congress, in turn, must be sensitive to the concerns of corporations that help fund their campaigns.

In this political system, the actions of food companies are normal, legal, and thoroughly analogous to the workings of any other major industry – tobacco, for example – in influencing health experts, federal agencies, and Congress.[1] Promoting food raises more complicated issues than promoting tobacco, however, in that food is required for life and causes problems only when consumed inappropriately. As this book will demonstrate, the primary mission of food companies, like that of tobacco companies, is to sell products. Food companies are not health or social service agencies, and nutrition becomes a factor in corporate thinking only when it can help sell food. The ethical choices involved in such thinking are considered all too rarely.

Early in the 20th century, when the principal causes of death and disability among Americans were infectious diseases related in part to inadequate intake of calories and nutrients, the goals of health officials, nutritionists and the food industry were identical – to encourage people to eat more of all kinds of food. Throughout that century, improvements in the US economy affected the way we eat in important ways: we obtained access to foods of greater variety, our diets improved and nutrient deficiencies gradually declined. The principal nutritional problems among Americans shifted to those of *over-nutrition* – eating too much food or too much of certain kinds of food. Overeating causes its own set of health problems; it deranges metabolism, makes people overweight and increases the likelihood of 'chronic' diseases – coronary heart disease, certain cancers, diabetes, hypertension, stroke and others – that now are leading causes of illness and death in any overfed population.

People may believe that the effects of diet on chronic disease are less important than those of cigarette smoking, but each contributes to about one-fifth of annual deaths in the US. Addressing cigarette smoking requires only a single change in behaviour: don't smoke. But because people must eat to survive, advice about dietary improvements is much more complicated: eat this food instead of that food, or eat less. As this book explains, the 'eat less' message is at the root of much of the controversy over nutrition advice. It directly conflicts with food industry demands that people eat more of their products. Thus food companies work hard to oppose and undermine 'eat less' messages.

I first became aware of the food industry as an influence on government nutrition policies and on the opinions of nutrition experts when I moved to Washington DC, in 1986 to work for the Public Health Service. My job was to manage the editorial production of the first – and as yet only – *Surgeon General's Report on Nutrition and Health*, which appeared as a 700-page book in the summer of 1988.[2] This report was an ambitious government effort to summarize the entire body of research linking dietary factors such as fat, saturated fat, cholesterol, salt, sugar and alcohol to leading chronic diseases. My first day on the job, I was given the rules: no matter what the research indicated, the report could not recommend 'eat less meat' as a way to reduce intake of saturated fat, nor could it suggest restrictions on intake of any other category of food. In the industry-friendly climate of the Reagan administration, the producers of foods that might be affected by such advice would complain to their beneficiaries in Congress, and the report would never be published.

This scenario was no paranoid fantasy; federal health officials had endured a decade of almost constant congressional interference with their dietary recommendations. As I discuss in Part I, agency officials had learned to avoid such interference by resorting to euphemisms, focusing recommendations on nutrients rather than on the foods that contain them and giving a positive spin to any restrictive advice about food. Whereas 'eat less beef' called the industry to arms, 'eat less saturated fat' did not. 'Eat less sugar' sent sugar producers right to Congress, but that industry could live with 'choose a diet moderate in sugar'. When released in 1988, the *Surgeon General's Report* recommended 'choose lean meats' and suggested limitations on sugar intake only for people particularly vulnerable to dental cavities.

Subsequent disputes have only reinforced sensitivities to political expediency when formulating advice about diet and health. Political expediency explains in part why no subsequent *Surgeon General's Report* has appeared, even though Congress passed a law in 1990 requiring that one be issued biannually. After ten years of working to develop a *Surgeon General's Report on Dietary Fat and Health* – surely needed to help people understand the endless debates about the relative health consequences of eating saturated, monounsaturated, trans-saturated and total fat – the government abandoned the project, ostensibly because the science base had become increasingly complex and equivocal. A more compelling reason must have been lack of interest in completing such a report in the election year of 2000. Authoritative recommendations about fat intake would have had to include some 'eat less' advice if for no other reason than because fat is so concentrated in calories – it contains 9 calories per gram, compared to 4 each for protein or carbohydrate[3] – and obesity is a major health concern. Because saturated fat and trans-saturated fat raise risks for heart disease, and the principal sources of such fats in American diets are meat, dairy, cooking fats, and fried, fast and processed foods, 'eat less' advice would provoke the producers and sellers of these foods to complain to their friends in Congress.

Since 1988, in my role as chair of an academic department of nutrition, a member of federal advisory committees, a speaker at public and professional meetings, a frequent commentator on nutrition issues to the press, and (on occasion) a consultant to food companies, I have become increasingly convinced that many of the nutritional problems of Americans – not least of them obesity – can be traced to the food industry's imperative to encourage people to *eat more* in order to generate sales and increase income in a highly competitive marketplace. Ambiguous dietary advice is only one result of this imperative. As I explain in Part II, the industry also devotes enormous financial and other resources to lobbying Congress and federal agencies, forming partnerships and alliances with professional nutrition organizations, funding research on food and nutrition, publicizing the results of selected research studies favourable to industry, sponsoring professional journals and conferences, and making sure that influential groups – federal officials, researchers, doctors, nurses, school teachers and the media – are aware of the benefits of their products.

Later sections of the book describe the ways in which such actions affect food issues of particular public interest and debate. Part III reviews the most egregious example of food company marketing practices: the deliberate use of young children as sales targets and the conversion of schools into vehicles for selling 'junk' foods high in calories but low in nutritional value. Part IV explains how the supplement industry manipulated the political process to achieve a sales environment virtually free of government oversight of the content, safety and advertising claims for its products. In Part V, I describe how the food industry markets 'junk' foods as health foods by adding nutrients and calling them 'functional' foods or 'nutraceuticals'. The concluding chapter summarizes the significance of the issues raised by these examples and offers some options for choosing a healthful diet in an overabundant food system. Finally, the Appendix introduces some terms and concepts used in the field of nutrition and discusses issues that help explain why nutrition research is so controversial and so often misunderstood.

Before plunging into these accounts, some context may prove useful. This introduction addresses the principal questions that bear on the matters discussed in this book: What are we supposed to eat to stay healthy? Does diet really matter? Is there a significant gap between what we are supposed to eat and what we do eat? The answers to these questions constitute a basis for examining the central concern of this book: Does the food industry have anything to do with poor dietary practices? As a background for addressing that question, this introduction provides some fundamental facts about today's food industry and its marketing philosophies and strategies, and also points to some common themes that appear throughout the book.

What is a 'Healthy' Diet?

To promote health as effectively as possible, diets must achieve balance: they must provide *enough* energy (calories) and vitamins, minerals and other essential nutrients to prevent deficiencies and support normal metabolism. At the same time, they must not include *excessive* amounts of these and other nutritional factors that might promote development of chronic diseases. Fortunately, the optimal range of intake of most dietary components is quite broad. It is obvious that people throughout the world eat many different foods and follow many different dietary patterns, many of which promote excellent health and longevity. As with other behavioural factors that affect health, diet interacts with individual genetic variation as well as with cultural, economic and geographical factors that affect infant survival and adult longevity. On a *population* basis, the balance between getting enough of the *right* kinds of nutrients and avoiding too much of the *wrong* kinds is best achieved by diets that include large proportions of energy from plant foods – fruits, vegetables and grains.

The longest-lived populations in the world, such as some in Asia and the Mediterranean, traditionally eat diets that are largely plant-based. Such diets tend to be relatively low in calories but high in vitamins, minerals, fibre and other components of plants (phytochemicals) that – acting together – protect against disease. Dietary patterns that best promote health derive most energy from plant foods, considerably less from foods of animal origin (meat, dairy, eggs) and even less from foods high in animal fats and sugars. The *Food Guide Pyramid* of the US Department of Agriculture (USDA) is meant to depict a plant-based diet that promotes optimal health (see Figure 14.1).

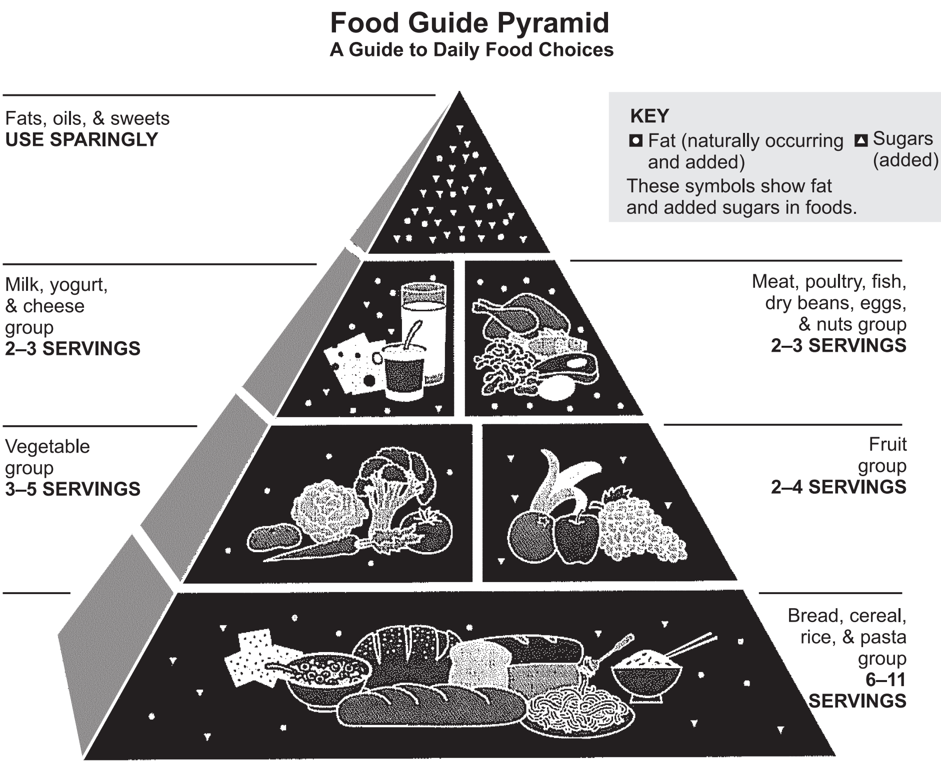

Figure 14.1 *The 1992 USDA Food Guide Pyramid recommends a hierarchical – and therefore controversial – dietary pattern based mainly on foods of plant origin*

Does Diet Matter?

In addition to consuming largely plant-based diets, people in long-lived populations are physically active and burn up any excess calories they obtain from food. An active life-style helps mitigate the harmful effects of overeating, but the evidence for the importance of diet in health also is overwhelming. Disease by chronic disease, scientists consistently have demonstrated the health benefits of diets rich in fruit and vegetables, limited in foods and fats of animal origin and balanced in calories. Comprehensive reports in the late 1980s from the US and Europe documented the evidence available at that time and subsequent research has only strengthened those conclusions.[4]

Health experts suggest conservatively that the combination of poor diet, sedentary life-style and excessive alcohol consumption contributes to about 400,000 of the 2,000,000 or so annual deaths in the US – about the same number and proportion affected by cigarette smoking. Women who follow dietary recommendations display half the rates of coronary heart disease observed among women who eat poor diets, and those who also are active and do not smoke cigarettes have less than one-fifth the risk. The diet-related medical costs for just six health conditions – coronary heart disease, cancer, stroke, diabetes, hypertension and obesity – exceeded $70 billion in 1995. Some authorities believe that just a 1 per cent reduction in intake of saturated fat across the population would prevent more than 30,000 cases of coronary heart disease annually and save more than a billion dollars in health care costs. Such estimates indicate that even small dietary changes can produce large benefits when their effects are multiplied over an entire population.[5]

Conditions that can be prevented by eating better diets have roots in childhood. Rates of obesity are now so high among American children that many exhibit metabolic abnormalities formerly seen only in adults. The high blood sugar due to 'adult-onset' (insulin-resistant type II) diabetes, the high blood cholesterol and the high blood pressure now observed in younger and younger children constitute a national scandal. Such conditions increase the risk of coronary heart disease, cancer, stroke and diabetes later in life. From the late 1970s to the early 1990s, the prevalence of *overweight* nearly doubled – from 8 per cent to 14 per cent among children aged 6–11 and from 6 per cent to 12 per cent among adolescents. The proportion of overweight adults rose from 25 per cent to 35 per cent in those years. Just between 1991 and 1998, the rate of adult *obesity* increased from 12 per cent to nearly 18 per cent. Obesity contributes to increased health care costs, thereby becoming an issue for everyone, overweight or not.[6]

The cause of overweight is an excess of calories consumed over calories burned off in activity. People gain weight because they eat too many calories or are too inactive for the calories they eat. Genetics affects this balance, of course, because heredity predisposes some people to gain weight more easily than others, but genetic changes in a population occur too slowly to account for the sharp increase in weight gain over such a short time period. The precise relationship between the diet side and the activity side of the weight 'equation' is uncertain and still under investigation, in part because we lack accurate methods for assessing the activity levels of populations. People seem to be spending more time at sedentary activities such as watching television and staring at computer screens, and the number of hours spent watching television is one of the best predictors of overweight, but surveys do not report enough of a decrease in activity levels to account for the current rising rates of obesity.[7] This gap leaves overeating as the most probable cause of excessive weight gain.

Do Americans Overeat?

Overweight itself constitutes ample evidence that many Americans consume more calories than they burn off, but other sources of information also confirm the idea that people are eating too much food. The calories provided by the US food supply increased from 3,300 per capita in 1970 to 3,800 in the late 1990s, an increase of 500 per day. These supply figures tend to overestimate amounts of food actually consumed because they do not account for wastage, but they do give some indication of trends. Surveys that ask about actual dietary intake tend to underestimate caloric intake, because people find it difficult to remember dietary details but easier to give answers that seem to please investigators. Even so, dietary intake surveys also indicate that people are eating more than they were in the 1970s. Then, people reported eating an average of about 1800 calories per day. By 1996 they reported 2000 calories per day. No matter how unrealistically low these figures may be and how imprecise the sources of data, all suggest a trend toward caloric intakes that exceed average levels of caloric expenditure.[8]

In addition to revealing how much people are eating, food supply and dietary intake surveys indicate changes in food habits over time. The increase in calories reflects an increase in consumption of *all* major food groups: more vegetables and more fruit (desirable), but also more meat and dairy foods, and more foods high in fat and sugar (less desirable). The most pronounced change is in beverage consumption. The supply of whole milk fell from 25.5 gallons per capita per year in 1970 to just 8.5 gallons in 1997. The supply of low-fat milk rose from 5.8 to 15.5 gallons during the same time, but that of soft drinks rose from 24.3 to 53 gallons. To reduce fat intake, people replaced whole milk with lower-fat varieties (same nutrients, fewer calories), but they undermined this beneficial change by increasing consumption of soft drinks (sugar calories, no nutrients). Despite the introduction of artificial sweeteners, the supply of calorie-laden sweeteners – sugars, corn sweeteners and honey – has gone up. Because of the inconsistencies in data, the trend in fat intake is harder to discern. Fat in the food supply increased by 25 per cent from 1970 to the late 1990s, but dietary intake surveys do not find people to be eating more of it. Although USDA nutritionists conclude that Americans are eating less fat, they also observe that people are eating more food outside the home, where foods are higher in fat and calories.[9]

Figure 14.2 *This 'food consumption' pyramid compares the average number of servings consumed per day by the US population in the mid-1990s to the servings recommended by the Food Guide Pyramid*

In comparison to the *Pyramid*, American diets clearly are out of balance, as shown in Figure 14.2. Top-heavy as it is, this illustration *underestimates* the discrepancy between recommended and actual servings. For one thing, the USDA's serving estimates are based on self-reports of dietary intake, but people tend to underreport the intake of foods considered undesirable and to overestimate the consumption of 'healthy' foods. For another, the USDA calculates numbers of servings by adding up the individual components of mixed dishes and assigning them to the appropriate *Pyramid* categories. This means that the flour in cookies is assigned to the grain category, the apples in pies to the fruit group, and the potatoes in chips to the vegetable group. This method may yield more precise information about nutrient intake, but it makes high-calorie, low-nutrient foods appear as better nutritional choices than they may be. The assignment of the tomatoes in ketchup to the vegetable group only reinforces the absurdity of the USDA's famous attempt during the Reagan administration to count ketchup as a vegetable in the federal school lunch programme.[10]

The comparison hides other unwelcome observations. USDA nutritionists report that the average consumption of whole-grain foods is just one serving per day, well below recommended levels. And although the number of vegetable servings appears close to recommendations, *half* the servings come from just three foods: iceberg lettuce, potatoes (frozen, fresh and those used for chips and fries) and canned tomatoes. When fried potatoes are excluded from the count, vegetable servings fall below three per day. Even though the consumption of reduced-fat dairy products has doubled since 1970, half the dairy servings still come from high-fat, high-calorie cheese and whole milk. Servings of added fats are at least one-third higher than they should be and servings of caloric sweeteners are half again as high. From such observations, we can conclude that the increased calories in American diets come from eating more food in general, but especially more of foods high in fat (meat, dairy, fried foods, grain dishes with added fat), sugar (soft drinks, juice drinks, desserts), and salt (snack foods).[11] It can hardly be a coincidence that these are just the foods that are most profitable to the food industry and that it most vigorously promotes.

The US Food Industry

This book uses the term food industry to refer to companies that produce, process, manufacture, sell and serve foods, beverages and dietary supplements. In a larger sense, the term encompasses the entire collection of enterprises involved in the production and consumption of food and beverages: producers and processors of food crops and animals (agribusiness); companies that make and sell fertilizer, pesticides, seeds and feed; those that provide machinery, labour, real estate and financial services to farmers; and others that transport, store, distribute, export, process and market foods after they leave the farm. It also includes the food service sector – food carts, vending machines, restaurants, bars, fast food outlets, schools, hospitals, prisons and workplaces – and associated suppliers of equipment and serving materials. This vast 'food-and-fiber' system generates a trillion dollars or more in sales every year, accounts for 13 per cent of the US gross national product (GNP) and employs 17 per cent of the country's labour force. Of the $800 billion or so a year that the public spends directly on food and drink, alcoholic beverages account for about $90 billion and the rest is distributed among retail food enterprises (54 per cent) and food service (46 per cent).[12]

The US food industry is the remarkably successful result of 20th-century trends that led from small farms to giant corporations, from a society that cooked at home to one that buys nearly half its meals prepared and consumed elsewhere, and from a diet based on 'whole' foods grown locally to one based largely on foods that have been processed in some way and transported long distances. These changes created a farm system that is much less labour-intensive and far more efficient and specialized. In 1900, 40 per cent of the population lived on farms, but today no more than 2 per cent do. Just since 1960, the number of farms has declined from about 3.2 million to 1.9 million, but their average size has increased by 40 per cent and their productivity by 82 per cent. Most farms today raise just a single commodity such as cattle, chickens, pigs, corn, wheat or soybeans. Many are part of a system of 'vertical' integration: ownership by one corporation of all stages of production and marketing. Chickens constitute an especially clear example. In the mid-1950s, chickens were raised in small flocks by many farmers; today, most are 'factory-farmed' in massive numbers under contract to a few large companies.[13]

Economic pressures force food and beverage companies to expand to tremendous size. In 2000, seven US companies – Philip Morris, ConAgra, Mars, IBP, Sara Lee, Heinz and Tyson Foods – ranked among the ten largest food companies in the world. Nestlé (Switzerland) ranked first, Unilever (UK/Netherlands) third, and Danone (France) sixth. Other US companies such as Coca-Cola, McDonald's, PepsiCo, Procter & Gamble and Roche (vitamins) ranked among the top 100 companies worldwide. In the US alone, just three companies – Philip Morris (Kraft Foods, Miller Brewing), ConAgra and RJR-Nabisco – accounted for nearly 20 per cent of all food expenditures in 1997. Table 14.1 lists the ten leading producers of packaged food products in the US in 2000, along with their annual sales and advertising budgets. The largest companies generated more than $30 billion each in annual sales, placing great pressure on smaller companies to merge. Such pressures also apply to supermarkets. Mergers among food and cigarette companies merit special interest. As described in Table 14.2, two of the four leading US cigarette companies, R. J. Reynolds and Philip Morris, bought – and sometimes swapped – food and beverage companies in manoeuvres designed to protect stockholders' investments against tobacco liability lawsuits.

The increasing consumption of food outside the home also has implications for the food industry – and for health. Table 14.3 lists the leading US food service companies by category: fast foods, restaurant chains, contract corporations and hotel operations. The highest-selling food service chains are sandwich houses and fast food chains. First among them is McDonald's; its 12,804 US outlets brought in $19.6 billion in 2000 sales, more than twice as much as its nearest competitor.

The greater efficiency, specialization and size of agriculture and food product manufacture have led to one of the great unspoken secrets about the American food system: over-abundance. As already noted, the US food supply – plus imports less exports – provides a daily average of 3800 calories per capita. This level is nearly twice the amount needed to meet the energy requirements of most women, one-third more than that needed by most men and much higher than that needed by babies, young children and the sedentary elderly. Even if, as the USDA estimates, 1100 of those calories might be wasted (as spoiled fruit, for example, or as oil for frying potatoes), the excess calories are a major problem for the food industry: they force competition. Even people who overindulge can eat only so much food, and choosing one food means rejecting others. Over-abundance alone is sufficient to explain why the annual growth rate of the American food industry is only a percentage point or two and why it has poked along at that low level for many years. It also explains why food companies compete so strenuously for consumer food dollars,

Table 14.1 *Sales and advertising expenditures for the ten leading producers of packaged food products in the US*

Company and examples	*Food sales [total sales], 1999 ($ billions)*	*Advertising, US, 1998 ($ millions)*

Table 14.2 *Cigarette companies' ownership of food and beverage companies: chronology*

1969	Philip Morris, Inc. acquires 53% of Miller Brewing.
1970	Philip Morris buys the remaining 47% of Miller Brewing.
1978	Philip Morris acquires 97% of Seven-Up.
1985	R.J. Reynolds buys Nabisco Foods for $4.9 billion, creating RJR-Nabisco, a public company.
	Philip Morris buys General Foods for $5.6 billion.
1986	Philip Morris sells Seven-Up to PepsiCo.
1988	Philip Morris buys Kraft, Inc. for $13.6 billion. RJR-Nabisco announces plans to 'go private'; offers to buy outstanding public shares for $17 billion.
1989	The investment firm Kohlberg Kravis Roberts leverages a buyout of RJR-Nabisco for $24.9 billion, leaving the private company with $20 billion in debt. Philip Morris combines Kraft and General Foods to form Kraft General Foods.
1990	Philip Morris acquires Jacobs Suchard, a Swiss coffee and confectionary company, for $4.1 billion.
1991	Kohlberg Kravis Roberts sells stocks in RJR-Nabisco to the public. The bestseller *Barbarians at the Gate* (New York: HarperCollins, 1991) describes the takeover events.
1993	Kraft General Foods (Philip Morris) buys Nabisco ready-to-eat cereals from RJR-Nabisco for $448 million.
1995	Kraft General Foods reorganizes into Kraft Foods, Inc. In an effort to shore up stock prices, RJR-Nabisco becomes a holding company for R. J. Reynolds (tobacco) and Nabisco Holdings (food); sells 19% of shares in Nabisco Holdings to the public.
1996	Philip Morris buys shares of Brazil's leading chocolate company, Industrias de Chocolate Lacta, S.A.; Kraft Foods acquires Taco Bell.
1999	RJR-Nabisco sells its international tobacco business; separates and renames its domestic tobacco (R. J. Reynolds Tobacco Holdings) and food businesses (Nabisco Group Holdings). This action leaves Nabisco Group Holdings with 81% of Nabisco as its sole asset (Nabisco Holdings has the remainder), only $1 billion in debt, but with uncertain liability for tobacco lawsuits. Philip Morris said to be interested in buying Nabisco; acquires Philadelphia cream cheese; reports revenues exceeding $78 billion.
2000	Philip Morris buys Nabisco Holdings for $14.9 billion, creating a company that earned combined revenues of $34.9 billion and profits of $5.5 billion in 1999. This purchase leaves R.J. Reynolds Tobacco Holdings with $1.5 billion in cash and the tobacco liability.

Marketing Imperatives

To sell their products, companies appeal to the reasons why people choose to eat one food rather than another. These reasons are numerous, complex and not always understood, mainly because we select diets within the context of the social, economic and cultural environment in which we live. When food or money is scarce, people do not have the luxury of choice; for much of the world's population, the first consideration is getting *enough* food to meet biological needs for energy and nutrients. It is one of the great ironies of nutrition that the traditional plant-based diets consumed by the poor in many countries, some of which are among the world's finest cuisines, are ideally suited to meeting nutritional needs as long as caloric intake is adequate. Once people raised on such foods survive the hazards of infancy, their diets (and their active life-styles) support an adulthood relatively free of chronic disease until late in life.[14]

Also ironic is that once people become better off, they are observed to enter a 'nutrition transition' in which they abandon traditional plant-based diets and begin eating more meat, fat and processed foods. The result is a sharp increase in obesity and related chronic diseases. In 2000 the number of overweight people in the world for the first time matched the number of undernourished people – 1.1 billion each. Even in an industrialized country such as France, dietary changes can be seen to produce rapid increases in the prevalence of chronic disease. In the early 1960s, the French diet contained just 25 per cent of calories from fat, but the proportion now approaches 40 per cent as a result of increased intake of meat, dairy and processed foods. Despite contentions that the French are protected from heart disease by their wine consumption (a phenomenon known as the French Paradox), they are getting fatter by the day and experiencing increased rates of diabetes and other health consequences of overeating and overweight. The nutrition transition reflects both taste preferences and economics. Food animals raised in feedlots eat grains, which makes meat more expensive to produce and converts it into a marker of prosperity. Once people have access to meat, they usually do not return to eating plant-based diets unless they are forced to do so by economic reversal or are convinced to do so for reasons of religion, culture or health.[15]

Humans do not innately know how to select a nutritious diet; we survived in evolution because nutritious foods were readily available for us to hunt or gather. In an economy of over-abundance, food companies can sell products only to people who *want* to buy them. Whether consumer demands drive food sales or the industry creates such demands is a matter of debate, but much industry effort goes into trying to figure out what the public 'wants' and how to meet such 'needs'. Nearly all research on this issue yields the same conclusion. When food is plentiful and people can afford to buy it, basic biological needs become less compelling and the principal determinant of food choice is personal preference. In turn, personal preferences may be influenced by religion and other cultural factors, as well as by considerations of convenience, price and nutritional value. To sell food in an economy of abundant food choices, companies must worry about those other determinants much more than about the nutritional value of their products – unless the nutrient content helps to entice buyers.[16] Thus the food industry's marketing imperatives principally concern four factors: taste, cost, convenience and (as we shall see) public confusion.

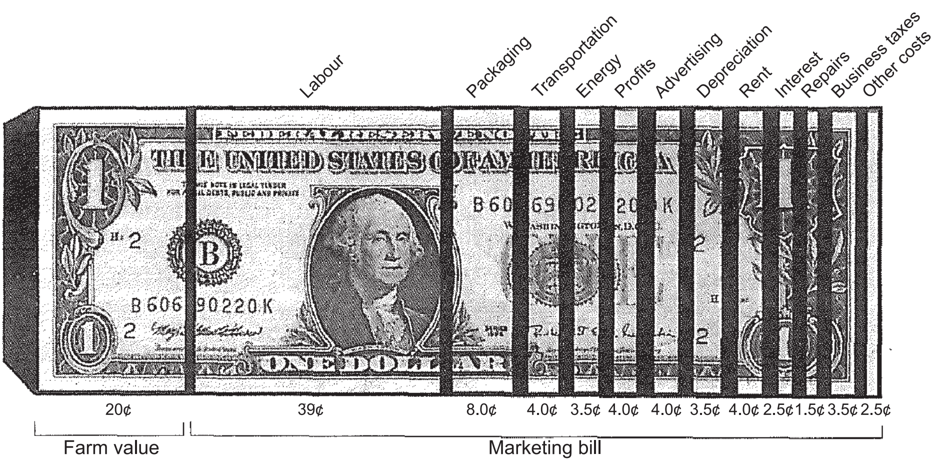
Taste: make foods sweet, fat and salty

Adults prefer foods that taste, look and smell good, are familiar and provide variety, but these preferences are influenced strongly by family and ethnic background, level of education, income, age and gender. When asked, most of us say we choose foods because we like them, by which we mean the way we respond to their flavour, smell, sight and texture. Most of us prefer sweet foods and those that are 'energy-dense' (high in calories, fat and sugar), and we like the taste of salt. The universality of such preferences suggests some physiologic basis for all of them, but the research is most convincing for sweetness. Ripe fruit is innately sweet and appealing, but many of us can and do learn to enjoy the complex and sometimes bitter taste of vegetables. Whether a taste for meat is innate or acquired can be debated, but many people like to eat steak, hamburgers and fried chicken, along with desserts, soft drinks and salty snacks. Such preferences drive the development of new food products as well as the menus in restaurants.

Cost: add value but keep prices low

One result of over-abundance is pressure to add value to foods through processing. The producers of raw foods receive only a fraction of the price that consumers pay at the supermarket. In 1998, for example, an average of 20 per cent of retail cost – the 'farm value' of the food – was returned to its producers. This percentage, which has been declining for years, is unequally distributed. Producers of eggs, beef and chicken receive 50 per cent to 60 per cent of retail cost, whereas producers of vegetables receive as little as 5 per cent. Once foods get to the supermarket, the proportion represented by the farm value declines further in proportion to the extent of processing. The farm value of frozen peas is 13 per cent, of canned tomatoes 9 per cent, of oatmeal 7 per cent and of corn syrup just 4 per cent.[17]

As shown in Figure 14.3, the remaining 80 per cent of the food dollar goes for labour, packaging, advertising and other such value-enhancing activities. Conversion



Source: USDA *FoodReview* 2000; 23(3): 27–30

Figure 14.3 *The distribution of the US food dollar: 80% of food expenditures go to categories other than the 'farm value' of the food itself* of potatoes (cheap) to potato chips (expensive) to those fried in artificial fats or coated in soybean flour or herbal supplements (even more expensive) is an example of how value is added to basic food commodities. Added value explains why the cost of the corn in Kellogg's Corn Flakes is less than 10 per cent of the retail price. With this kind of pricing distribution, food companies are more likely to focus on developing added-value products than to promote consumption of fresh fruits and vegetables, particularly because opportunities for adding value to such foods are limited. Marketers can add value to fruits and vegetables by selling them frozen, canned or pre-cut, but even the most successful of such products – pre-packaged and branded 'baby' carrots, salad mixes and precut fruit – raise consumer concerns about freshness and price.

Despite the focus on adding value, over-abundance keeps food costs low compared to those anywhere else in the world, and this is due only in part to our high average income. The average American pays less than 10 per cent of income for food. People in low-income countries like Tanzania pay more than 70 per cent of income for food and those in middle-income countries like the Philippines up to 55 per cent but even people in high-income countries like Japan pay as much as 20 per cent. Americans, however, strongly resist price increases. In the US, lower prices stimulate sales, especially the sale of higher-cost items; price is a more important factor in the consumer's choice of steak than of ground beef. Cost is so important a factor in food choice that economists are able to calculate the effect of a change in price on nutrient intake. They estimate that a decline in the price of meat, for example, causes the average intake of calcium and iron to rise but also increases the consumption of calories, fat, saturated fat and cholesterol.[18]

A more important reason for low food prices is that the government subsidizes food production in ways that are rarely evident. The most visible subsidies are price supports for sugar and milk, but taxpayers also support production quotas, market quotas, import restrictions, deficiency payments, lower tax rates, low-cost land leases, land management, water rights and marketing and promotion programmes for major food commodities. The total cost of agricultural subsidies rose rapidly at the end of the 20th century from about $18 billion in 1996 to $28 billion in 2000. As we shall see in Part II, the large agricultural corporations that most benefit from federal subsidies spare no effort to persuade Congress and the administration to continue and increase this largesse.[19]

Convenience: make eating fast

Convenience is a principal factor driving the development of value-added products. The demographic causes of demands for convenience are well understood. In the last quarter of the 20th century, the proportion of women with children who entered the work force greatly expanded, and many people began to work longer hours to make ends meet. In 1900, women accounted for 21 per cent of the labour force and married women for less than 6 per cent but by 1999, women – married or not – accounted for more than 60 per cent. The structure of American families changed once there was no longer a housewife who stayed home and cooked.

Working women were unable or unwilling to spend as much time grocery shopping, cooking and cleaning up after meals.[20]

Societal changes easily explain why nearly half of all meals are consumed outside the home, a quarter of them as fast food and the practice of snacking nearly doubled from the mid-1980s to the mid-1990s. They explain the food industry's development of pre-packaged sandwiches, salads, entrees and desserts, as well as such innovations as 'power' bars, yogurt and pasta in tubes, pre-packaged cereal in a bowl, salad bars, hot-food bars, take-out chicken, supermarket 'home meal replacements', McDonald's shaker salads, chips pre-packaged with dips and foods designed to be eaten directly from the package. Whether these 'hyper-convenient' products will outlast the competition remains to be seen, but survival is more likely to depend on taste and price than on nutrient content. Many of these products are high in calories, fat, sugar or salt but are marketed as nutritious because they contain added vitamins.

Nutritionists and traditionalists may lament such developments, because convenience overrides not only considerations of health but also the social and cultural meanings of meals and mealtimes. Many food products relegate cooking to a low-priority chore and encourage trends toward one-dish meals, fewer side dishes, fewer ingredients, larger portions to create leftovers, almost nothing cooked 'from scratch' and home-delivered meals ordered by phone, fax or Internet. Interpreting the meaning of these developments no doubt will occupy sociologists and anthropologists for decades. In the meantime, convenience adds value to foods and stimulates the food industry to create even more products that can be consumed quickly and with minimal preparation.

Confusion: keep the public puzzled

Many people find it difficult to put nutrition advice into practice, not least because they view the advice as ephemeral – changing from one day to the next. This view is particularly unfortunate because advice to eat more fruits and vegetables and to avoid overweight as a means to promote health has remained constant for half a century. Confusion about nutrition is quite understandable, however. People obtain information about diet and health from the media – newspapers, magazines, television, radio and more recently the Internet. These outlets get much of their information from research publications, experts and the public relations representatives of food and beverage companies. Media outlets require *news* and reporters are partial to breakthroughs, simple take-home lessons and controversies. A story about the benefits of single nutrients can be entertaining, but 'eat your veggies' is old news. It is more interesting to read about a study 'proving' that calcium does or does not prevent bone loss than a report that patiently explains the other factors – nutrients, foods, drinks, exercise – that might influence calcium balance in the body. Although foods contain hundreds of nutrients and other components that influence health, and although people eat diets that contain dozens of different foods, reporters rarely discuss study results in their broader dietary context.[21] News outlets are not alone in focusing on single nutrients or foods; researchers also do so. It is easier to study the effects of vitamin E on heart disease risk than it is to try to explain how current dietary *patterns* are associated with declining rates of coronary heart disease. Research on the effects of single nutrients is more likely to be funded and the results are more likely to garner headlines, especially if they conflict with previous studies. In the meantime, basic dietary advice remains the same – constant, but dull.

Newspaper sales and research grants may benefit from confusion over dietary advice, but the greatest beneficiary of public confusion is the food industry. Virtually every food and beverage product is represented by a trade association or public relations firm whose job it is to promote a positive image of that item among consumers, professionals and the media. These groups – and their lobbyists – can take advantage of the results of single-nutrient research to claim that products containing the beneficial nutrient promote health and to demand the right to make that claim on package labels. If people are confused about nutrition, they will be more likely to accept such claims at face value. It is in the interest of food companies to have people believe that there is no such thing as a 'good' food (except when it is theirs); that there is no such thing as a 'bad' food (especially not theirs); that all foods (especially theirs) can be incorporated into healthful diets; and that balance, variety and moderation are the keys to healthful diets – which means that no advice to restrict intake of their particular product is appropriate. The *Pyramid*, however, clearly indicates that some foods are better than others from the standpoint of health.

Promoting 'Eat More'

In a competitive food marketplace, food companies must satisfy stockholders by encouraging more people to eat more of their products. They seek new audiences among children, among members of minority groups or internationally. They expand sales to existing as well as new audiences through advertising but also by developing new products designed to respond to consumer 'demands'. In recent years, they have embraced a new strategy: increasing the sizes of food portions. Advertising, new products, and larger portions all contribute to a food environment that promotes eating more, not less.

Advertise, advertise, advertise

Advertising operates so far below the consciousness of everyone – the public, most nutritionists I know and survey researchers – that it hardly ever gets mentioned as an influence on food choice. The subliminal nature of food and beverage advertising is a tribute to its ubiquity, as well as to the sophistication of the agencies that produce it. Extraordinary amounts of money and talent go into this effort. Food and food service companies spend more than $11 billion annually on direct media advertising in magazines, newspapers, radio, television and billboards. Some examples of expenditures by specific companies are given in Table 14.1. In 1999 McDonald's spent $627.2 million, Burger King $403.6 million, Taco Bell $206.5 million and Coke and Diet Coke $174.4 million on direct media advertising. Even small products have impressive advertising budgets, as illustrated by expenditures of $117 million for Wrigley's chewing gum and nearly $80 million for M&M candies.[22] For every dollar spent that 'measured' way, the companies spend another two dollars on discount incentives – for example, coupons for consumers and 'slotting fees' for retailers to ensure space on supermarket shelves. In total, food companies spent more than $33 billion annually at the turn of the century to advertise and promote their products to the public. Most of this astronomical sum is used to promote the most highly processed, elaborately packaged and fast foods. Nearly 70 per cent of food advertising is for convenience foods, candy and snacks, alcoholic beverages, soft drinks and desserts, whereas just 2.2 per cent is for fruits, vegetables, grains or beans.[23] Figure 14.4 illustrates the disproportionate distribu-

Figure 14.4 *The Produce for Better Health Foundation, a government–industry partnership to promote consumption of fruits and vegetables, created this 'food marketing' pyramid to illustrate the disproportionate expenditure of advertising dollars in comparison to dietary recommendations* tion of marketing expenditures relative to dietary recommendations. Although the costs of marketing may appear huge, they amount to just a small fraction of sales.

Advertising costs for any single, nationally distributed food product far exceed (often by 10–50 times) federal expenditures for promotion of the *Pyramid* or to encourage people to eat more fruit and vegetables. Of the more than $300 million that the USDA spends annually on nutrition education, most goes for research projects, the educational components of agricultural extension and other activities that target relatively few people. Despite protestations by marketers that advertising is a minor element in food choice and that the ubiquity of advertising dilutes its impact, they continue to use it to sell products. Successful campaigns are carefully researched, targeted to specific groups and repeated frequently. Advertising promotes the sales of specific food products and in proportion to the amount spent, as shown for commodities such as milk, cheese, grapefruit juice and orange juice. Food sales increase with the intensity, repetition and visibility of the advertising message.[24] Promotion of nutritional advantages (low-fat, no cholesterol, high-fibre, calcium-added) increases sales, as does the use of health claims (lowers cholesterol, prevents cancer). Cigarette company-owned food advertisers are particularly adept at using charity to sell food products, as shown in Figure 14.5. Advertising sells food to children, a phenomenon well understood by advertisers of tobacco and beer. Advertisers deliberately promote food brands among children and more active demands for advertised foods.

Introduce new products

To food and beverage companies, added value and convenience are driving forces for new-product development. Whether the industry creates new products in response to consumer demand or generates demand by creating the products is difficult to untangle; most likely, both interact. Regardless, new-product introductions have increased greatly since the mid-1980s when there were fewer than 6000 annually. In the peak year of 1995, manufacturers introduced 16,900 food and beverage products but the number has since declined. All told, 116,000 packaged foods and beverages have been introduced since 1990, and these joined a marketplace that now contains 320,000 items competing for supermarket shelf space large enough to hold just 50,000.[12] The glut of food products means that only the most highly promoted products will succeed; even these may encounter difficulties if they do not taste good, raise questions about health or safety or cost too much.

In 1998, manufacturers introduced slightly more than 11,000 new products (Table 14.4). More than two-thirds of those products are condiments, candy and snacks, baked goods, soft drinks and dairy products (cheese products and ice cream novelties) – foods largely allocated to the top of the *Pyramid*. Slightly more than one-fourth are 'nutritionally enhanced' so that they can be marketed as low in fat, cholesterol, salt or sugar or as higher in fibre, calcium or vitamins. Some such

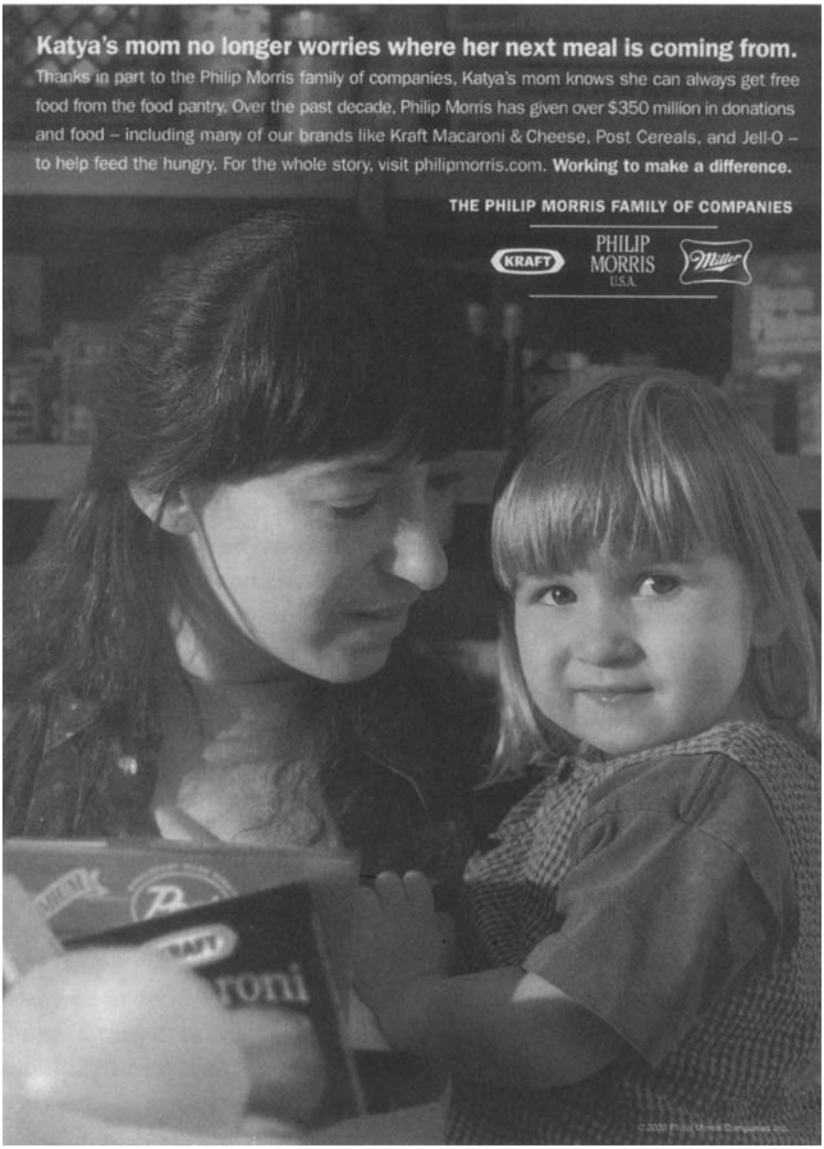

Figure 14.5 *This Philip Morris advertisement for its philanthropic food donations appeared in Walking, a health and fitness magazine aimed at young women, in October 2000. No advertisements for cigarettes appear in the magazine. Philip Morris owns Kraft Foods and Miller Beer*

products, among them no-fat cookies, vitamin-enriched cereals and calcium-fortified juice drinks, contain so much sugar that they belong at the top of the *Pyramid*. Developing such foods has only one purpose: to attract sales.

Table 14.4 *Major categories of the 11,037 new food products introduced in 1998*

Product category	*Number of new products*
Candy, gum, snacks	2065
Condiments	1994
Beverages	1547
Bakery foods	1178
Dairy foods	940
Processed meats	728
Entrees, pre-prepared	678
Fruits and vegetables	375
Soups	299
Desserts	117
Pet foods	105
Breakfast cereals	84
Baby foods	35

Serve larger portions

'Eat more' marketing methods extend beyond billboards and television commercials; they also include substantial increases in the sizes of food packages and restaurant portions. When the *Pyramid* recommends 6–11 grain servings, these amounts seem impossibly large with reference to restaurant, fast or take-out foods. The *Pyramid* serving numbers, however, refer to portion size *standards* defined by the USDA: a standard grain serving is one slice of white bread, one ounce of ready-to-eat cereals or muffins, or one-half cup of rice or pasta. Therefore, a single bakery muffin weighing 7 ounces, or one medium container of movie-theatre popcorn (16 cups), easily meets or exceeds a day's grain allowances. Larger servings of course contain more calories. The largest movie-theatre soft drink contains 800 calories if not too diluted with ice. Larger portions can contribute to weight gain unless people compensate with diet and exercise. From an industry standpoint, however, larger portions make good marketing sense. The cost of food is low relative to labour and other factors that add value. Large portions attract customers who flock to all-you-can-eat restaurants and order double-scoop ice cream cones because the relative prices discourage the choice of smaller portions. It does not require much mathematical skill to understand that the larger portions of McDonald's french fries are a better buy than the 'small' when they are 40 per cent cheaper per ounce.[25]

Taken together, advertising, convenience, larger portions and (as we shall see) the added nutrients in foods otherwise high in fat, sugar and salt all contribute to an environment that promotes 'eat more'. Because dietary advice affects sales, food companies also conduct systematic, pervasive and unrelenting – but far less apparent –

campaigns to convince government officials, health organizations and nutrition professionals that their products are healthful or harmless, to undermine any suggestion to the contrary, and to ensure that federal *dietary guidelines* and food guides will help promote sales.

Issues and Themes

Over-abundant food and its consequences occur in the context of increasing centralization and globalization of the food industry and of altered patterns of work, welfare and government. The food system is only one aspect of society, but it is unusual in its universality: everyone eats. Because food affects lives as well as livelihoods, the situations discussed in this book generate substantial attention from the industry and the government, as well as from advocates, nutrition and health professionals, the media and the public at large. In this book's discussions of specific topics and incidents, several themes occur. Some of these themes touch on matters central to the functioning of democratic institutions and are worth noting as they emerge in the chapters that follow.

One such theme is the 'paradox of plenty', the term used by historian Harvey Levenstein to refer to the social consequences of food over-abundance, among them the sharp disparities in diet and health between rich and poor.[26] Wealthier people usually are healthier and they choose better diets. They also tend to avoid smoking cigarettes, to drink alcohol in moderation if at all and to be better educated and more physically active. Health habits tend to cluster in patterns, making it difficult to tease out the effects of diet from that of any other behavioural factor. Most paradoxical in the presence of food over-abundance is that large numbers of people in the US and elsewhere do not have enough to eat. The economic expansion of the 20th century differentially favoured people whose income was higher than average and provided much smaller gains for the poor. As noted earlier, when people in developing countries go through a 'nutrition transition', they increase the intake of meat, fat and processed foods, gain weight and develop risk factors for diseases of over-consumption. In the US, low-income groups seem to have about the same nutrient intake as people who are better off, but they choose diets higher in calories, fat, meat and sugar, and they display higher rates of obesity and chronic diseases. The income gap between rich and poor can be explained by the functioning of economic and related educational systems. The gaps in diet and health are economically based, but they also derive in part from the social status attached to certain kinds of food – meat for the poor and health foods for the rich, for example. Food and beverage companies reinforce this gap when they seek new marketing opportunities among minority groups or in low-income neighbourhoods. The alcoholic beverage industry is especially adept in marketing to 'disenfranchised' groups.[27]

A second theme is the conflict between scientific and other kinds of belief systems. Although most scientists view scientific methods – testing hypotheses by controlled experiments – as inherently valid and truthful, we shall see that many people regard science as just one of a number of belief systems of equal validity and importance. Religious beliefs, concerns about animal rights and views of the fundamental nature of society, for example, influence the way people think about food. So do vested interests. Like any other kind of science, nutrition science is more a matter of probabilities than of absolutes and is, therefore, subject to interpretation. Interpretation, in turn, depends on point of view. Government agencies invoke science as a basis for regulatory decisions. Food and supplement companies invoke science to oppose regulations and dietary advice that might adversely affect sales. Advocates invoke science to question the safety of products perceived as undesirable. In contrast, scientists and food producers, who might benefit from promoting research results, nutritional benefits or safety, tend to view other-than-scientific points of view as inherently irrational. Debates about food issues that affect broad aspects of society often focus on scientific proof of safety whether or not safety constitutes the 'real' issue, largely because alternative belief systems cannot be validated by scientific methods.[28]

The third theme constitutes this book's central thesis: diet is a political issue. Because dietary advice affects food sales, and because companies demand a favourable regulatory environment for their products, dietary practices raise political issues that cut right to the heart of democratic institutions. Nearly all of the situations discussed in this book involve struggles over who decides what people should eat and whether a given food is 'healthy'. As a result, they inevitably involve struggles over the way government balances corporate against public interests. Such struggles are fundamental to the functioning of the American political system. They are revealed whenever a company attacks its critics as 'food police' or justifies self-interested actions as a defence of freedom of choice or exclusion of 'Big Brother' government from personal decisions. They are expressed whenever food companies use financial relationships with members of Congress, political leaders and nutrition and health experts to weaken the regulatory ability of federal agencies and whenever they go to court to block unfavourable regulatory decisions. Despite the overwhelmingly greater resources of food companies in defending their own interests we shall see that consumer advocates sometimes can be highly effective in convincing Congress, federal agencies and the courts to take action in the public interest. On that optimistic note, let's begin by tracing the history of federal dietary advice to the public and the ways in which such advice has been influenced by the actions of the food industry.

Your Trusted Friends

E. Schlosser

Before entering the Ray A. Kroc Museum, you have to walk through McStore. Both sit on the ground floor of McDonald's corporate headquarters, located at One McDonald's Plaza in Oak Brook, Illinois. The headquarters building has oval windows and a grey concrete facade – a look that must have seemed space-age when the building opened three decades ago. Now it seems stolid and drab, an architectural relic of the Nixon era. It resembles the American embassy compounds that always used to attract anti-war protesters, student demonstrators, flag burners. The eighty-acre campus of Hamburger University, McDonald's managerial training centre, is a short drive from headquarters. Shuttle buses constantly go back and forth between the campus and McDonald's Plaza, ferrying clean-cut young men and women in khakis who've come to study for their 'Degree in Hamburgerology'. The course lasts two weeks and trains a few thousand managers, executives and franchisees each year. Students from out of town stay at the Hyatt on the McDonald's campus. Most of the classes are devoted to personnel issues, teaching lessons in teamwork and employee motivation, promoting 'a common McDonald's language' and 'a common McDonald's culture'. Three flagpoles stand in front of McDonald's Plaza, the heart of the hamburger empire. One flies the Stars and Stripes, another flies the Illinois state flag and the third flies a bright red flag with golden arches.

You can buy bean-bag McBurglar dolls at McStore, telephones shaped like french fries, ties, clocks, key chains, golf bags and duffel bags, jewellery, baby clothes, lunch boxes, mouse pads, leather jackets, postcards, toy trucks and much more, all of it bearing the stamp of McDonald's. You can buy T-shirts decorated with a new version of the American flag. The fifty white stars have been replaced by a pair of golden arches.

At the back of McStore, past the footsteps of Ronald McDonald stenciled on the floor, past the shelves of dishes and glassware, a bronze bust of Ray Kroc marks the entrance to his museum. Kroc was the founder of the McDonald's Corporation, and his philosophy of QSC and V – Quality, Service, Cleanliness and Value – still guide

Reprinted from 'Your trusted friends' from *Fast Food Nation: The Dark Side of the All-American Meal* by Eric Schlosser, 2002, London and New York, Chapter 2, pp31–57. Reproduced by permission of Penguin Books Ltd. Reprinted by permission of Houghton Mifflin Company.

it. The man immortalized in bronze is balding and middle-aged, with smooth cheeks and an intense look in his eyes. A glass display case nearby holds plaques, awards and letters of praise. 'One of the high-lights of my sixty-first birthday celebration', President Richard Nixon wrote in 1974, 'was when Tricia suggested we needed a "break" on our drive to Palm Springs, and we turned in at McDonald's. I had heard for years from our girls that the "Big Mac" was really something special, and while I've often credited Mrs. Nixon with making the best hamburgers in the world, we are both convinced that McDonald's runs a close second... The next time the cook has a night off we will know where to go for fast service, cheerful hospitality – and probably one of the best food buys in America.' Other glass cases contain artifacts of Kroc's life, mementos of his long years of struggle and his twilight as a billionaire. The museum is small and dimly lit, displaying each object with reverence. The day I visited, the place was empty and still. It didn't feel like a traditional museum, where objects are coolly numbered, catalogued and described. It felt more like a shrine.

Many of the exhibits at the Ray A. Kroc Museum incorporate neat technological tricks. Dioramas appear and then disappear when certain buttons are pushed. The voices of Kroc's friends and coworkers – one of them identified as a McDonald's 'vice president of individuality' – boom from speakers at the appropriate cue. Darkened glass cases are suddenly illuminated from within, revealing their contents. An artwork on the wall, when viewed from the left, displays an image of Ray Kroc. Viewed from the right, it shows the letters QSC and V. The museum does not have a life-size, Audio-Animatronic version of McDonald's founder telling jokes and anecdotes. But one wouldn't be out of place. An interactive exhibit called 'Talk to Ray' shows video clips of Kroc appearing on the *Phil Donahue Show,* being interviewed by Tom Snyder and chatting with Reverend Robert Schuller at the altar of Orange County's Crystal Cathedral. 'Talk to Ray' permits the viewer to ask Kroc as many as thirty-six predetermined questions about various subjects; old videos of Kroc supply the answers. The exhibit wasn't working properly the day of my visit. Ray wouldn't take my questions and so I just listened to him repeating the same speeches.

The Disneyesque tone of the museum reflects, among other things, many of the similarities between the McDonald's Corporation and the Walt Disney Company. It also reflects the similar paths of the two men who founded these corporate giants. Ray Kroc and Walt Disney were both from Illinois; they were born a year apart, Disney in 1901, Kroc in 1902; they knew each other as young men, serving together in the same World War I ambulance corps; and they both fled the Midwest and settled in southern California, where they played central roles in the creation of new American industries. The film critic Richard Schickel has described Disney's powerful inner need 'to order, control, and keep clean any environment he inhabited'. The same could easily be said about Ray Kroc, whose obsession with cleanliness and control became one of the hallmarks of his restaurant chain. Kroc cleaned the holes in his mop wringer with a toothbrush.

Kroc and Disney both dropped out of high school and later added the trappings of formal education to their companies. The training school for Disney's theme-park employees was named Disneyland University. More importantly, the two men shared the same vision of America, the same optimistic faith in technology, the same conservative political views. They were charismatic figures who provided an overall corporate vision and grasped the public mood, relying on others to handle the creative and financial details. Walt Disney neither wrote, nor drew the animated classics that bore his name. Ray Kroc's attempts to add new dishes to McDonald's menu – such as Kolacky, a Bohemian pastry and the Hulaburger, a sandwich featuring grilled pineapple and cheese – were unsuccessful. Both men, however, knew how to find and motivate the right talent. While Disney was much more famous and achieved success sooner, Kroc may have been more influential. His company inspired more imitators, wielded more power over the American economy – and spawned a mascot even more famous than Mickey Mouse.

Despite all their success as businessmen and entrepreneurs, as cultural figures and advocates for a particular brand of Americanism, perhaps the most significant achievement of these two men lay elsewhere. Walt Disney and Ray Kroc were masterful salesmen. They perfected the art of selling things to children. And their success led many others to aim marketing efforts at kids, turning America's youngest consumers into a demographic group that is now avidly studied, analysed and targeted by the world's largest corporations.

Walt and Ray

Ray Kroc took the McDonald brothers' Speedee Service System and spread it nationwide, creating a fast food empire. Although he founded a company that came to symbolize corporate America, Kroc was never a buttoned-down corporate type. He was a former jazz musician who'd played at speakeasies – and at a bordello, on at least one occasion – during Prohibition. He was a charming, funny and indefatigable travelling salesman who endured many years of disappointment, a Willy Loman who finally managed to hit it big in his early sixties. Kroc grew up in Oak Park, Illinois, not far from Chicago. His father worked for Western Union. As a high school freshman, Ray Kroc discovered the joys of selling while employed at his uncle's soda fountain. 'That was where I learned you could influence people with a smile and enthusiasm', Kroc recalled in his autobiography, *Grinding It Out*, 'and sell them a sundae when what they'd come for was a cup of coffee.'

Over the years, Kroc sold coffee beans, sheet music, paper cups, Florida real estate, powdered instant beverages called 'Malt-a-Plenty' and 'Shake-a-Plenty', a gadget that could dispense whipped cream or shaving lather, square ice cream scoops and a collapsible table-and-bench combination called 'Fold-a-Nook' that retreated into the wall like a Murphy bed. The main problem with square scoops of ice cream, he found, was that they slid off the plate when you tried to eat them. Kroc used the same basic technique to sell all these things: he tailored his pitch to fit the buyer's tastes. Despite one setback after another, he kept at it, always convinced that success was just around the corner. 'If you believe in it, and you believe in it hard', Kroc later told audiences, 'it's impossible to fail. I don't care what it is – you can get it!'

Ray Kroc was selling milk-shake mixers in 1954 when he first visited the new McDonald's Self-Service Restaurant in San Bernardino. The McDonald brothers were two of his best customers. The Multimixer unit that Kroc sold could make five milk shakes at once. He wondered why the McDonald brothers needed eight of the machines. Kroc had visited a lot of restaurant kitchens, out on the road, demonstrating the Multimixer – and had never seen anything like the McDonald's Speedee Service System. 'When I saw it', he later wrote, 'I felt like some latter-day Newton who'd just had an Idaho potato caromed off his skull.' He looked at the restaurant 'through the eyes of a salesman' and envisioned putting a McDonald's at busy intersections all across the land.

Richard and 'Mac' McDonald were less ambitious. They were clearing $100,000 a year in profits from the restaurant, a huge sum in those days. They already owned a big house and three Cadillacs. They didn't like to travel. They'd recently refused an offer from the Carnation Milk Company, which thought that opening more McDonald's would increase the sales of milk shakes. Nevertheless, Kroc convinced the brothers to sell him the right to franchise McDonald's nationwide. The two could stay at home, while Kroc travelled the country, making them even richer. A deal was signed. Years later Richard McDonald described his first memory of Kroc, a moment that would soon lead to the birth of the world's biggest restaurant chain: 'This little fellow comes in, with a high voice, and says, "hi".'

After finalizing the agreement with the McDonald brothers, Kroc sent a letter to Walt Disney. In 1917 the two men had both lied about their ages to join the Red Cross and see battle in Europe. A long time had clearly passed since their last conversation. 'Dear Walt', the letter said. 'I feel somewhat presumptuous addressing you in this way yet I feel sure you would not want me to address you any other way. My name is Ray A. Kroc... I look over the Company A picture we had taken at Sound Beach, Conn., many times and recall a lot of pleasant memories.' After the warm-up came the pitch: 'I have very recently taken over the national franchise of the McDonald's system. I would like to inquire if there may be an opportunity for a McDonald's in your Disneyland Development.'

Walt Disney sent Kroc a cordial reply and forwarded his proposal to an executive in charge of the theme park's concessions. Disneyland was still under construction, its opening was eagerly awaited by millions of American children, and Kroc may have had high hopes. According to one account, Disney's company asked Kroc to raise the price of McDonald's french fries from ten cents to fifteen cents; Disney would keep the extra nickel as payment for granting the concession; and the story ends with Ray Kroc refusing to gouge his loyal customers. The account seems highly unlikely, a belated effort by someone at McDonald's to put the best spin on a sales pitch that went nowhere. When Disneyland opened in July of 1955 – an event that Ronald Reagan co-hosted for ABC – it had food stands run by Welch's, Stouffer's and Aunt Jemima's, but no McDonald's. Kroc was not yet in their league. His recollection of Walt Disney as a young man, briefly mentioned in *Grinding It Out*, is not entirely flattering. 'He was regarded as a strange duck', Kroc wrote of Disney, 'because whenever we had time off and went out on the town to chase girls, he stayed in camp drawing pictures.'

Whatever feelings existed between the two men, Walt Disney proved in many respects to be a role model for Ray Kroc. Disney's success had come much more quickly. At the age of 21 he'd left the Midwest and opened his own movie studio in Los Angeles. He was famous before turning 30. In *The Magic Kingdom* (1997) Steven Watts describes Walt Disney's efforts to apply the techniques of mass production to Hollywood moviemaking. He greatly admired Henry Ford and introduced an assembly line and a rigorous division of labour at the Disney Studio, which was soon depicted as a 'fun factory'. Instead of drawing entire scenes, artists were given narrowly defined tasks, meticulously sketching and inking Disney characters while supervisors watched them and timed how long it took them to complete each cel. During the 1930s the production system at the studio was organized to function like that of an automobile plant. 'Hundreds of young people were being trained and fitted', Disney explained, 'into a machine for the manufacture of entertainment.'

The working conditions at Disney's factory, however, were not always fun. In 1941 hundreds of Disney animators went on strike, expressing support for the Screen Cartoonists Guild. The other major cartoon studios in Hollywood had already signed agreements with the union. Disney's father was an ardent socialist, and Disney's films had long expressed a populist celebration of the common man. But Walt's response to the strike betrayed a different political sensibility. He fired employees who were sympathetic to the union, allowed private guards to rough up workers on the picket line, tried to impose a phony company union, brought in an organized crime figure from Chicago to rig a settlement and placed a full-page ad in *Variety* that accused leaders of the Screen Cartoonists Guild of being communists. The strike finally ended when Disney acceded to the union's demands. The experience left him feeling embittered. Convinced that communist agents had been responsible for his troubles, Disney subsequently appeared as a friendly witness before the House Un-American Activities Committee, served as a secret informer for the FBI and strongly supported the Hollywood blacklist. During the height of labour tension at his studio, Disney had made a speech to a group of employees, arguing that the solution to their problems rested not with a labour union, but with *a good day's work*. 'Don't forget this', Disney told them, 'it's the law of the universe that the strong shall survive and the weak must fall by the way, and I don't give a damn what idealistic plan is cooked up, nothing can change that.'

Decades later, Ray Kroc used similar language to outline his own political philosophy. Kroc's years on the road as a travelling salesman – carrying his own order forms and sample books, knocking on doors, facing each new customer alone and having countless doors slammed in his face – no doubt influenced his view of humanity. 'Look, it is ridiculous to call this an industry', Kroc told a reporter in 1972, dismissing any high-minded analysis of the fast food business. 'This is not. This is rat eat rat, dog eat dog. I'll kill'em, and I'm going to kill'em before they kill me. You're talking about the American way of survival of the fittest.'

While Disney backed right-wing groups and produced campaign ads for the Republican Party, Kroc remained aloof from electoral politics – with one notable exception. In 1972, Kroc gave $250,000 to President Nixon's re-election campaign, breaking the gift into smaller donations, funnelling the money through various state and local Republican committees. Nixon had every reason to like McDonald's, long before tasting one of its hamburgers. Kroc had never met the president; the gift did not stem from any personal friendship or fondness. That year the fast food industry was lobbying Congress and the White House to pass new legislation – known as the 'McDonald's bill' – that would allow employers to pay 16- and 17-year-old kids wages 20 per cent lower than the minimum wage. Around the time of Kroc's $250,000 donation, McDonald's crew members earned about $1.60 an hour. The sub-minimum wage proposal would reduce some wages to $1.28 an hour.

The Nixon administration supported the McDonald's bill and permitted McDonald's to raise the price of its Quarter Pounders, despite the mandatory wage and price controls restricting other fast food chains. The size and the timing of Kroc's political contribution sparked Democratic accusations of influence peddling. Outraged by the charges, Kroc later called his critics 'sons of bitches'. The uproar left him wary of backing political candidates. Nevertheless, Kroc retained a soft spot for Calvin Coolidge, whose thoughts on hard work and self-reliance were prominently displayed at McDonald's corporate headquarters.

Better Living

Despite a passionate opposition to socialism and to any government meddling with free enterprise, Walt Disney relied on federal funds in the 1940s to keep his business afloat. The animators' strike had left the Disney Studio in a precarious financial condition. Disney began to seek government contracts – and those contracts were soon responsible for 90 per cent of his studio's output. During World War II, Walt Disney produced scores of military training and propaganda films, including *Food Will Win the War, High-Level Precision Bombing* and *A Few Quick Facts About Venereal Disease*. After the war, Disney continued to work closely with top military officials and military contractors, becoming America's most popular exponent of Cold War science. For audiences living in fear of nuclear annihilation, Walt Disney became a source of reassurance, making the latest technical advances seem marvellous and exciting. His faith in the goodness of American technology was succinctly expressed by the title of a film that the Disney Studio produced for Westinghouse Electric: *The Dawn of Better Living*.

Disney's passion for science found expression in 'Tomorrowland', the name given to a section of his theme park and to segments of his weekly television show. Tomorrowland encompassed everything from space travel to the household appliances of the future, depicting progress as a relentless march toward greater convenience for consumers. And yet, from the very beginning, there was a dark side to this Tomorrowland. It celebrated technology without moral qualms. Some of the science it espoused later proved to be not so benign – and some of the scientists it promoted were unusual role models for the nation's children.

In the mid-1950s Wernher von Braun co-hosted and helped produce a series of Disney television shows on space exploration. 'Man in Space' and the other Tomorrowland episodes on the topic were enormously popular and fuelled public support for an American space programme. At the time, von Braun was the US Army's leading rocket scientist. He had served in the same capacity for the German army during World War II. He had been an early and enthusiastic member of the Nazi party, as well as a major in the SS. At least 20,000 slave labourers, many of them Allied prisoners of war, died at Dora-Nordhausen, the factory where von Braun's rockets were built. Less than ten years after the liberation of Dora-Nordhausen, von Braun was giving orders to Disney animators and designing a ride at Disneyland called Rocket to the Moon. Heinz Haber, another key Tomorrowland adviser – and eventually the chief scientific consultant to Walt Disney Productions – spent much of World War II conducting research on high-speed, high-altitude flight for the Luftwaffe Institute for Aviation Medicine. In order to assess the risks faced by German air force pilots, the institute performed experiments on hundreds of inmates at the Dachau concentration camp near Munich. The inmates who survived these experiments were usually killed and then dissected. Haber left Germany after the war and shared his knowledge of aviation medicine with the US Army Air Force. He later co-hosted Disney's 'Man in Space' with von Braun. When the Eisenhower administration asked Walt Disney to produce a show championing the civilian use of nuclear power, Heinz Haber was given the assignment. He hosted the Disney broadcast called 'Our Friend the Atom' and wrote a popular children's book with the same title, both of which made nuclear fission seem fun, instead of terrifying. 'Our Friend the Atom' was sponsored by General Dynamics, a manufacturer of nuclear reactors. The company also financed the atomic submarine ride at Disneyland's Tomorrowland.

The future heralded at Disneyland was one in which every aspect of American life had a corporate sponsor. Walt Disney was the most beloved children's entertainer in the country. He had unrivalled access to impressionable young minds – and other corporations, with other agendas to sell, were eager to come along for the ride. Monsanto built Disneyland's House of the Future, which was made of plastic. General Electric backed the Carousel of Progress, which featured an Audio-Animatronic housewife, standing in her futuristic kitchen, singing about 'a great big beautiful tomorrow'. Richfield Oil offered Utopian fantasies about cars and a ride aptly named Autopia. 'Here you leave Today', said the plaque at the entrance to Disneyland, 'and enter the world of Yesterday, Tomorrow, and Fantasy.'

At first, Disneyland offered visitors an extraordinary feeling of escape; people had never seen anything like it. The great irony, of course, is that Disney's suburban, corporate world of Tomorrow would soon become the Anaheim of Today. Within a decade of its opening, Disneyland was no longer set amid a rural idyll of orange groves, it was stuck in the middle of cheap motels, traffic jams on the Santa

Ana freeway, fast food joints and industrial parks. Walt Disney frequently slept at his small apartment above the firehouse in Disneyland's Main Street, US. By the early 1960s, the hard realities of Today were more and more difficult to ignore, and Disney began dreaming of bigger things, of Disney World, a place even farther removed from the forces he'd helped to unleash, a fantasy that could be even more thoroughly controlled.

Among other cultural innovations, Walt Disney pioneered the marketing strategy now known as 'synergy'. During the 1930s, he signed licensing agreements with dozens of firms, granting them the right to use Mickey Mouse on their products and in their ads. In 1938 *Snow White* proved a turning point in film marketing: Disney had signed 70 licensing deals prior to the film's release. Snow White toys, books, clothes, snacks and records were already for sale when the film opened. Disney later used television to achieve a degree of synergy beyond anything that anyone had previously dared. His first television broadcast, *One Hour in Wonderland* (1950), culminated in a promotion for the upcoming Disney film *Alice in Wonderland*. His first television series, *Disneyland* (1954), provided weekly updates on the construction work at his theme park. ABC, which broadcast the show, owned a large financial stake in the Anaheim venture. Disneyland's other major investor, Western Printing and Lithography, printed Disney books such as *The Walt Disney Story of Our Friend the Atom*. In the guise of televised entertainment, episodes of *Disneyland* were often thinly disguised infomercials, promoting films, books, toys, an amusement park – and, most of all, Disney himself, the living, breathing incarnation of a brand, the man who neatly tied all the other commodities together into one cheerful, friendly, patriotic idea.

Ray Kroc could only dream, during McDonald's tough early years, of having such marketing tools at his disposal. He was forced to rely instead on his wits, his charisma and his instinct for promotion. Kroc believed completely in whatever he sold and pitched McDonald's franchises with an almost religious fervour. He also knew a few things about publicity, having auditioned talent for a Chicago radio station in the 1920s and performed in nightclubs for years. Kroc hired a publicity firm led by a gag writer and a former MGM road manager to get McDonald's into the news. Children would be the new restaurant chain's target customers. The McDonald brothers had aimed for a family crowd and now Kroc improved and refined their marketing strategy. He'd picked the right moment. America was in the middle of a baby boom; the number of children had soared in the decade after World War II. Kroc wanted to create a safe, clean, all-American place for kids. The McDonald's franchise agreement required every new restaurant to fly the Stars and Stripes. Kroc understood that how he sold food was just as important as how the food tasted. He liked to tell people that he was really in show business, not the restaurant business. Promoting McDonald's to children was a clever, pragmatic decision. 'A child who loves our TV commercials', Kroc explained, 'and brings her grandparents to a McDonald's gives us two more customers.'

The McDonald's Corporation's first mascot was Speedee, a winking little chef with a hamburger for a head. The character was later renamed Archie McDonald. Speedy was the name of Alka-Seltzer's mascot, and it seemed unwise to imply any connection between the two brands. In 1960, Oscar Goldstein, a McDonald's franchisee in Washington DC, decided to sponsor *Bozo's Circus*, a local children's television show. Bozo's appearance at a McDonald's restaurant drew large crowds. When the local NBC station cancelled *Bozo's Circus* in 1963, Goldstein hired its star – Willard Scott, later the weatherman on NBC's *Today* show – to invent a new clown who could make restaurant appearances. An ad agency designed the outfit, Scott came up with the name Ronald McDonald and a star was born. Two years later the McDonald's Corporation introduced Ronald McDonald to the rest of the US through a major ad campaign. But Willard Scott no longer played the part. He was deemed too overweight; McDonald's wanted someone thinner to sell its burgers, shakes and fries.

The late-1960s expansion of the McDonald's restaurant chain coincided with declining fortunes at the Walt Disney Company. Disney was no longer alive and his vision of America embodied just about everything that kids of the 1960s were rebelling against. Although McDonald's was hardly a promoter of whole foods and psychedelia, it had the great advantage of seeming new – and there was something trippy about Ronald McDonald, his clothes and his friends. As McDonald's mascot began to rival Mickey Mouse in name recognition, Kroc made plans to create his own Disneyland. He was a highly competitive man who liked, whenever possible, to settle the score. 'If they were drowning to death', Kroc once said about his business rivals, 'I would put a hose in their mouth.' He planned to buy 1500 acres of land northeast of Los Angeles and build a new amusement park there. The park, tentatively called Western World, would have a cowboy theme. Other McDonald's executives opposed the idea, worried that Western World would divert funds from the restaurant business and lose millions. Kroc offered to option the land with his own money, but finally listened to his close advisers and scrapped the plan. The McDonald's Corporation later considered buying Astro World in Houston. Instead of investing in a large theme park, the company pursued a more decentralized approach. It built small Playlands and McDonaldlands all over the US.

The fantasy world of McDonaldland borrowed a good deal from Walt Disney's Magic Kingdom. Don Ament, who gave McDonaldland its distinctive look, was a former Disney set designer. Richard and Robert Sherman – who had written and composed, among other things, all the songs in Disney's *Mary Poppins*, Disneyland's 'It's a Great, Big, Beautiful Tomorrow' and 'It's a Small World, After All' – were enlisted for the first McDonaldland commercials. Ronald McDonald, Mayor McCheese and the other characters in the ads made McDonald's seem like more than just another place to eat. McDonaldland – with its hamburger patch, apple pie trees and Filet-O-Fish fountain – had one crucial thing in common with Disneyland. Almost everything in it was for sale. McDonald's soon loomed large in the imagination of toddlers, the intended audience for the ads. The restaurant chain evoked a series of pleasing images in a youngster's mind: bright colours, a playground, a toy, a clown, a drink with a straw, little pieces of food wrapped up like a present. Kroc had succeeded, like his old Red Cross comrade, at selling something intangible to children, along with their fries.

Kid Kustomers

Twenty-five years ago, only a handful of American companies directed their marketing at children – Disney, McDonald's, candy makers, toy makers, manufacturers of breakfast cereal. Today children are being targeted by phone companies, oil companies and automobile companies, as well as clothing stores and restaurant chains. The explosion in children's advertising occurred during the 1980s. Many working parents, feeling guilty about spending less time with their kids, started spending more money on them. One marketing expert has called the 1980s 'the decade of the child consumer'. After largely ignoring children for years, Madison Avenue began to scrutinize and pursue them. Major ad agencies now have children's divisions and a variety of marketing firms focus solely on kids. These groups tend to have sweet-sounding names: Small Talk, Kid Connection, Kid2Kid, the Gepetto Group, Just Kids, Inc. At least three industry publications – *Youth Market Alert, Selling to Kids* and *Marketing to Kids Report* – cover the latest ad campaigns and market research. The growth in children's advertising has been driven by efforts to increase not just current, but also future, consumption. Hoping that nostalgic childhood memories of a brand will lead to a lifetime of purchases, companies now plan 'cradle-to-grave' advertising strategies. They have come to believe what Ray Kroc and Walt Disney realized long ago – a person's 'brand loyalty' may begin as early as the age of two. Indeed, market research has found that children often recognize a brand logo before they can recognize their own name.

The discontinued Joe Camel ad campaign, which used a hip cartoon character to sell cigarettes, showed how easily children can be influenced by the right corporate mascot. A 1991 study published in the *Journal of the American Medical Association* found that nearly all of America's six-year-olds could identify Joe Camel, who was just as familiar to them as Mickey Mouse. Another study found that one-third of the cigarettes illegally sold to minors were Camels. More recently, a marketing firm conducted a survey in shopping malls across the country, asking children to describe their favorite TV ads. According to the CME KidCom Ad Traction Study II, released at the 1999 Kids' Marketing Conference in San Antonio, Texas, the Taco Bell commercials featuring a talking chihuahua were the most popular fast food ads. The kids in the survey also liked Pepsi and Nike commercials, but their favourite television ad was for Budweiser.

The bulk of the advertising directed at children today has an immediate goal. 'It's not just getting kids to whine', one marketer explained in *Selling to Kids*, 'it's giving them a specific reason to ask for the product.' Years ago sociologist Vance Packard described children as 'surrogate salesmen' who had to persuade other people, usually their parents, to buy what they wanted. Marketers now use different terms to explain the intended response to their ads – such as 'leverage', 'the nudge factor', 'pester power'. The aim of most children's advertising is straightforward: get kids to nag their parents and nag them well.

James U. McNeal, a professor of marketing at Texas A&M University, is considered America's leading authority on marketing to children. In his book *Kids As Cus-*

tomers (1992), McNeal provides marketers with a thorough analysis of 'children's requesting styles and appeals'. He classifies juvenile nagging tactics into seven major categories. A *pleading* nag is one accompanied by repetitions of words like 'please' or 'mom, mom, mom'. A *persistent* nag involves constant requests for the coveted product and may include the phrase 'I'm gonna ask just one more time'. *Forceful* nags are extremely pushy and may include subtle threats, like 'Well, then, I'll go and ask Dad'. *Demonstrative* nags are the most high-risk, often characterized by full-blown tantrums in public places, breath holding, tears, a refusal to leave the store. *Sugar-coated* nags promise affection in return for a purchase and may rely on seemingly heartfelt declarations like 'You're the best dad in the world'. *Threatening* nags are youthful forms of blackmail, vows of eternal hatred and of running away if something isn't bought. *Pity* nags claim the child will be heartbroken, teased or socially stunted if the parent refuses to buy a certain item. 'All of these appeals and styles may be used in combination', McNeal's research has discovered, 'but kids tend to stick to one or two of each that prove most effective … for their own parents.'

McNeal never advocates turning children into screaming, breath-holding monsters. He has been studying 'Kid Kustomers' for more than 30 years and believes in a more traditional marketing approach. 'The key is getting children to see a firm … in much the same way as [they see] mom or dad, grandma or grandpa', McNeal argues. 'Likewise, if a company can ally itself with universal values such as patriotism, national defense, and good health, it is likely to nurture belief in it among children.'

Before trying to affect children's behaviour, advertisers have to learn about their tastes. Today's market researchers not only conduct surveys of children in shopping malls, they also organize focus groups for kids as young as two or three. They analyse children's artwork, hire children to run focus groups, stage slumber parties and then question children into the night. They send cultural anthropologists into homes, stores, fast food restaurants and other places where kids like to gather, quietly and surreptitiously observing the behaviour of prospective customers. They study the academic literature on child development, seeking insights from the work of theorists such as Erik Erikson and Jean Piaget. They study the fantasy lives of young children, then apply the findings in advertisements and product designs.

Dan S. Acuff – the president of Youth Market System Consulting and the author of *What Kids Buy and Why* (1997) – stresses the importance of dream research. Studies suggest that until the age of six, roughly 80 per cent of children's dreams are about animals. Rounded, soft creatures like Barney, Disney's animated characters and the Teletubbies therefore have an obvious appeal to young children. The Character Lab, a division of Youth Market System Consulting, uses a proprietary technique called Character Appeal Quadrant Analysis to help companies develop new mascots. The technique purports to create imaginary characters who perfectly fit the targeted age group's level of cognitive and neurological development.

Children's clubs have for years been considered an effective means of targeting ads and collecting demographic information; the clubs appeal to a child's fundamental need for status and belonging. Disney's Mickey Mouse Club, formed in 1930, was one of the trailblazers. During the 1980s and 1990s, children's clubs proliferated, as corporations used them to solicit the names, addresses, zip codes and personal comments of young customers. 'Marketing messages sent through a club not only can be personalized', James McNeal advises, 'they can be tailored for a certain age or geographical group.' A well-designed and well-run children's club can be extremely good for business. According to one Burger King executive, the creation of a Burger King Kids Club in 1991 increased the sales of children's meals as much as 300 per cent.

The Internet has become another powerful tool for assembling data about children. In 1998 a federal investigation of websites aimed at children found that 89 per cent requested personal information from kids; only 1 per cent required that children obtain parental approval before supplying the information. A character on the McDonald's website told children that Ronald McDonald was 'the ultimate authority in everything'. The site encouraged kids to send Ronald an email revealing their favourite menu item at McDonald's, their favourite book, their favourite sports team – and their name. Fast food websites no longer ask children to provide personal information without first gaining parental approval; to do so is now a violation of federal law, thanks to the Children's Online Privacy Protection Act, which took effect in April of 2000.

Despite the growing importance of the Internet, television remains the primary medium for children's advertising. The effects of these TV ads have long been a subject of controversy. In 1978, the Federal Trade Commission (FTC) tried to ban all television ads directed at children seven years old or younger. Many studies had found that young children often could not tell the difference between television programming and television advertising. They also could not comprehend the real purpose of commercials and trusted that advertising claims were true. Michael Pertschuk, the head of the FTC, argued that children need to be shielded from advertising that preys upon their immaturity. 'They cannot protect themselves', he said, 'against adults who exploit their present-mindedness.'

The FTC's proposed ban was supported by the American Academy of Pediatrics, the National Congress of Parents and Teachers, the Consumers Union and the Child Welfare League, among others. But it was attacked by the National Association of Broadcasters, the Toy Manufacturers of America and the Association of National Advertisers. The industry groups lobbied Congress to prevent any restrictions on children's ads and sued in federal court to block Pertschuk from participating in future FTC meetings on the subject. In April of 1981, three months after the inauguration of President Ronald Reagan, an FTC staff report argued that a ban on ads aimed at children would be impractical, effectively killing the proposal. 'We are delighted by the FTC's reasonable recommendation', said the head of the National Association of Broadcasters.

The Saturday morning children's ads that caused angry debates 20 years ago now seem almost quaint. Far from being banned, TV advertising aimed at kids is now broadcast 24 hours a day, closed-captioned and in stereo. Nickelodeon, the

Disney Channel, the Cartoon Network and the other children's cable networks are now responsible for about 80 per cent of all television viewing by kids. None of these networks existed before 1979. The typical American child now spends about 21 hours a week watching television – roughly one and a half months of TV every year. That does not include the time children spend in front of a screen watching videos, playing video games or using the computer. Outside of school, the typical American child spends more time watching television than doing any other activity except sleeping. During the course of a year, he or she watches more than 30,000 TV commercials. Even the nation's youngest children are watching a great deal of television. About one-quarter of American children between the ages of two and five have a TV in their room.

Perfect Synergy

Although the fast food chains annually spend about $3 billion on television advertising, their marketing efforts directed at children extend far beyond such conventional ads. The McDonald's Corporation now operates more than 8000 playgrounds at its restaurants in the US. Burger King has more than 2000. A manufacturer of 'playlands' explains why fast food operators build these largely plastic structures: 'Playlands bring in children, who bring in parents, who bring in money.' As American cities and towns spend less money on children's recreation, fast food restaurants have become gathering spaces for families with young children. Every month about 90 per cent of American children between the ages of three and nine visit a McDonald's. The seesaws, slides and pits full of plastic balls have proven to be an effective lure. 'But when it gets down to brass tacks', a *Brandweek* article on fast food notes, 'the key to attracting kids is toys, toys, toys.'

The fast food industry has forged promotional links with the nation's leading toy manufacturers, giving away simple toys with children's meals and selling more elaborate ones at a discount. The major toy crazes of recent years – including Pokémon cards, Cabbage Patch Kids and Tamogotchis – have been abetted by fast food promotions. A successful promotion easily doubles or triples the weekly sales volume of children's meals. The chains often distribute numerous versions of a toy, encouraging repeat visits by small children and adult collectors who hope to obtain complete sets. In 1999 McDonald's distributed 80 different types of Furby. According to a publication called *Tomart's Price Guide to McDonald's Happy Meal Collectibles*, some fast food giveaways are now worth hundreds of dollars.

Rod Taylor, a *Brandweek* columnist, called McDonald's 1997 Teenie Beanie Baby giveaway one of the most successful promotions in the history of American advertising. At the time McDonald's sold about 10 million Happy Meals in a typical week. Over the course of ten days in April of 1997, by including a Teenie Beanie Baby with each purchase, McDonald's sold about 100 million Happy Meals. Rarely has a marketing effort achieved such an extraordinary rate of sales among its intended consumers. Happy Meals are marketed to children between the ages of three and nine; within ten days about four Teenie Beanie Baby Happy Meals were sold for every American child in that age group. Not all of those Happy Meals were purchased for children. Many adult collectors bought Teenie Beanie Baby Happy Meals, kept the dolls and threw away the food.

The competition for young customers has led the fast food chains to form marketing alliances not just with toy companies, but with sports leagues and Hollywood studios. McDonald's has staged promotions with the National Basketball Association and the Olympics. Pizza Hut, Taco Bell and KFC signed a three-year deal with the NCAA. Wendy's has linked with the National Hockey League. Burger King and Nickelodeon, Denny's and Major League Baseball, McDonald's and the Fox Kids Network have all formed partnerships that mix advertisements for fast food with children's entertainment. Burger King has sold chicken nuggets shaped like Teletubbies. McDonald's now has its own line of children's videos starring Ronald McDonald. *The Wacky Adventures of Ronald McDonald* is being produced by Klasky-Csupo, the company that makes *Rugrats* and *The Simpsons*. The videos feature the McDonaldland characters and sell for $3.49. 'We see this as a great opportunity', a McDonald's executive said in a press release, 'to create a more meaningful relationship between Ronald and kids.'

All of these cross-promotions have strengthened the ties between Hollywood and the fast food industry. In the past few years, the major studios have started to recruit fast food executives. Susan Frank, a former director of national marketing for McDonald's, later became a marketing executive at the Fox Kids Network. She now runs a new family-oriented cable network jointly owned by Hallmark Entertainment and the Jim Henson Company, creator of the Muppets. Ken Snelgrove, who for many years worked as a marketer for Burger King and McDonald's, now works at MGM. Brad Ball, a former senior vice president of marketing at McDonald's, is now the head of marketing for Warner Brothers. Not long after being hired, Ball told the *Hollywood Reporter* that there was little difference between selling films and selling hamburgers. John Cywinski, the former head of marketing at Burger King, became the head of marketing for Walt Disney's film division in 1996, then left the job to work for McDonald's. Forty years after Bozo's first promotional appearance at a McDonald's, amid all the marketing deals, giveaways and executive swaps, America's fast food culture has become indistinguishable from the popular culture of its children.

In May of 1996, the Walt Disney Company signed a ten-year global marketing agreement with the McDonald's Corporation. By linking with a fast food company, a Hollywood studio typically gains anywhere from $25 million to $45 million in additional advertising for a film, often doubling its ad budget. These licensing deals are usually negotiated on a per-film basis; the 1996 agreement with Disney gave McDonald's exclusive rights to that studio's output of films and videos. Some industry observers thought Disney benefited more from the deal, gaining a steady source of marketing funds. According to the terms of the agreement, Disney characters could never be depicted sitting in a McDonald's restaurant or eating any of the chain's food. In the early 1980s, the McDonald's Corporation had turned away offers to buy Disney; a decade later, McDonald's executives sounded a bit defensive about having given Disney greater control over how their joint promotions would be run. 'A lot of people can't get used to the fact that two big global brands with this kind of credibility can forge this kind of working relationship', a McDonald's executive told a reporter. 'It's about their theme parks, their next movie, their characters, their videos… It's bigger than a hamburger. It's about the integration of our two brands, long term.'

The life's work of Walt Disney and Ray Kroc had come full circle, uniting in perfect synergy. McDonald's began to sell its hamburgers and french fries at Disney's theme parks. The ethos of McDonaldland and of Disneyland, never far apart, have finally become one. Now you can buy a Happy Meal at the Happiest Place on Earth.

The Brand Essence

The best insight into the thinking of fast food marketers comes from their own words. Confidential documents from a recent McDonald's advertising campaign give a clear sense of how the restaurant chain views its customers. The McDonald's Corporation was facing a long list of problems. 'Sales are decreasing', one memo noted. 'People are telling us Burger King and Wendy's are doing a better job of giving … better food at the best price', another warned. Consumer research indicated that future sales in some key areas were at risk. 'More customers are telling us', an executive wrote, 'that McDonald's is a big company that just wants to sell … sell as much as it can.' An emotional connection to McDonald's that customers had formed 'as toddlers' was now eroding. The new radio and television advertising had to make people feel that McDonald's still cared about them. It had to link the McDonald's of today to the one people loved in the past. 'The challenge of the campaign', wrote Ray Bergold, the chain's top marketing executive, 'is to make customers believe that McDonald's is their "Trusted Friend."'

According to these documents, the marketing alliances with other brands were intended to create positive feelings about McDonald's, making consumers associate one thing they liked with another. Ads would link the company's french fries 'to the excitement and fanaticism people feel about the NBA'. The feelings of pride inspired by the Olympics would be used in ads to help launch a new hamburger with more meat than the Big Mac. The link with the Walt Disney Company was considered by far the most important, designed to 'enhance perceptions of Brand McDonald's'. A memo sought to explain the underlying psychology behind many visits to McDonald's: parents took their children to McDonald's because they 'want the kids to love them … it makes them feel like a good parent'. Purchasing something from Disney was the '*ultimate*' way to make kids happy, but it was too expensive to do every day. The advertising needed to capitalize on these feelings, letting parents know that 'ONLY MCDONALD'S MAKES IT EASY TO GET A BIT OF DISNEY MAGIC'. The ads aimed at 'minivan parents' would carry an unspoken message about taking your children to McDonald's: 'It's an easy way to feel like a good parent.'

The fundamental goal of the 'My McDonald's' campaign that stemmed from these proposals was to make a customer feel that McDonald's 'cares about me' and 'knows about me'. A corporate memo introducing the campaign explained: 'The essence McDonald's is embracing is "Trusted Friend" … "Trusted Friend" captures all the goodwill and the unique emotional connection customers have with the McDonald's experience … [Our goal is to make] customers believe McDonald's is their "Trusted Friend." Note: this should be done without using the words "Trusted Friend"… Every commercial [should be] honest … Every message will be in good taste and feel like it comes from a trusted friend.' The words 'trusted friend' were never to be mentioned in the ads because doing so might prematurely 'wear out a brand essence' that could prove valuable in the future for use among different national, ethnic and age groups. Despite McDonald's faith in its trusted friends, the opening page of this memo said in bold red letters: 'ANY UNAUTHORIZED USE OR COPYING OF THIS MATERIAL MAY LEAD TO CIVIL OR CRIMINAL PROSECUTION.'

McTeachers and Coke Dudes

Not satisfied with marketing to children through playgrounds, toys, cartoons, movies, videos, charities and amusement parks, through contests, sweepstakes, games and clubs, via television, radio, magazines and the Internet, fast food chains are now gaining access to the last advertising-free outposts of American life. In 1993 District 11 in Colorado Springs started a nationwide trend, becoming the first public school district in the US to place ads for Burger King in its hallways and on the sides of its school buses. Like other school systems in Colorado, District 11 faced revenue shortfalls, thanks to growing enrolments and voter hostility to tax increases for education. The initial Burger King and King Sooper ad contracts were a disappointment for the district, gaining it just $37,500 a year – little more than $1 per student. In 1996, school administrators decided to seek negotiating help from a professional, hiring Dan DeRose, president of DD Marketing, Inc., of Pueblo, Colorado. DeRose assembled special advertising packages for corporate sponsors. For $12,000, a company got five school-bus ads, hallway ads in all 52 of the district's schools, ads in their school newspapers, a stadium banner, ads over the stadium's public-address system during games and free tickets to high school sporting events.

Within a year, DeRose had nearly tripled District 11's ad revenues. But his greatest success was still to come. In August of 1997, DeRose brokered a ten-year deal that made Coca-Cola the district's exclusive beverage supplier, bringing the schools up to $11 million during the life of the contract (minus DD Marketing's fee). The deal also provided free use of a 1998 Chevy Cavalier to a District 11 high school senior, chosen by lottery, who had good grades and a perfect attendance record.

District 11's marketing efforts were soon imitated by other school districts in Colorado, by districts in Pueblo, Fort Collins, Denver and Cherry Creek. Administrators in Colorado Springs did not come up with the idea of using corporate sponsorship to cover shortfalls in a school district's budget. But they took it to a whole new level, packaging it, systematizing it, leading the way. Hundreds of public school districts across the US are now adopting or considering similar arrangements. Children spend about seven hours a day, 150 days a year, in school. Those hours have in the past been largely free of advertising, promotion and market research – a source of frustration to many companies. Today the nation's fast food chains are marketing their products in public schools through conventional ad campaigns, classroom teaching materials and lunchroom franchises, as well as a number of unorthodox means.

The proponents of advertising in the schools argue that it is necessary to prevent further cutbacks; opponents contend that schoolchildren are becoming a captive audience for marketers, compelled by law to attend school and then forced to look at ads as a means of paying for their own education. America's schools now loom as a potential gold mine for companies in search of young customers. 'Discover your own river of revenue at the schoolhouse gates', urged a brochure at the 1997 Kids Power Marketing Conference. 'Whether it's first-graders learning to read or teenagers shopping for their first car, we can guarantee an introduction of your product and your company to these students in the traditional setting of the classroom.'

DD Marketing, with offices in Colorado Springs and Pueblo, has emerged as perhaps the nation's foremost negotiator of ad contracts for schools. Dan DeRose began his career as the founder of the Minor League Football System, serving in the late 1980s as both a team owner and a player. In 1991, he became athletic director at the University of Southern Colorado in Pueblo. During his first year, he raised $250,000 from corporate sponsors for the school's teams. Before long he was raising millions of dollars to build campus sports facilities. He was good at getting money out of big corporations and formed DD Marketing to use this skill on behalf of schools and nonprofits. Beverage companies and athletic shoe companies had long supported college sports programmes and during the 1980s began to put up the money for new high school scoreboards. Dan DeRose saw marketing opportunities that were still untapped. After negotiating his first Colorado Springs package deal in 1996, he went to work for the Grapevine-Colleyville School District in Texas. The district would never have sought advertising, its deputy superintendent told the *Houston Chronicle*, 'if it weren't for the acute need for funds'. DeRose started to solicit ads not only for the district's hallways, stadiums and buses, but also for its rooftops – so that passengers flying in or out of the nearby Dallas–Forth Worth airport could see them – and for its voicemail systems. 'You've reached Grapevine-Colleyville school district, proud partner of Dr Pepper', was a message that DeRose proposed. Although some people in the district were sceptical about the wild ideas of this marketer from Colorado, DeRose negotiated a $3.4 million dollar exclusive deal between the Grapevine-Colleyville School District and Dr Pepper in June of 1997. And Dr Pepper ads soon appeared on school rooftops.

Dan DeRose tells reporters that his work brings money to school districts that badly need it. By pitting one beverage company against another in bidding wars for exclusive deals, he's raised the prices being offered to schools. 'In Kansas City they were getting 67 cents a kid before', he told one reporter, 'and now they're getting $27.' The major beverage companies do not like DeRose and prefer not to deal with him. He views their hostility as a mark of success. He doesn't think that advertising in the schools will corrupt the nation's children and has little tolerance for critics of the trend. 'There are critics to penicillin', he told the *Fresno Bee*. In the three years following his groundbreaking contract for School District 11 in Colorado Springs, Dan DeRose negotiated agreements for 17 universities and 60 public school systems across the US, everywhere from Greenville, North Carolina, to Newark, New Jersey. His 1997 deal with a school district in Derby, Kansas, included the commitment to open a Pepsi GeneratioNext Resource Center at an elementary school. Thus far, DeRose has been responsible for school and university beverage deals worth more than $200 million. He typically accepts no money upfront, then charges schools a commission that takes between 25 and 35 per cent of the deal's total revenues.

The nation's three major beverage manufacturers are now spending large sums to increase the amount of soda that American children consume. Coca-Cola, Pepsi and Cadbury-Schweppes (the maker of Dr Pepper) control 90.3 per cent of the US market, but have been hurt by declining sales in Asia. Americans already drink soda at an annual rate of about 56 gallons per person – that's nearly 600 12-ounce cans of soda per person. Coca-Cola has set itself the goal of raising consumption of its products in the US by at least 25 per cent a year. The adult market is stagnant; selling more soda to kids has become one of the easiest ways to meet sales projections. 'Influencing elementary school students is very important to soft drink marketers', an article in the January 1999 issue of *Beverage Industry* explained, 'because children are still establishing their tastes and habits.' Eight-year-olds are considered ideal customers; they have about 65 years of purchasing in front of them. 'Entering the schools makes perfect sense', the trade journal concluded.

The fast food chains also benefit enormously when children drink more soda. The chicken nuggets, hamburgers and other main courses sold at fast food restaurants usually have the lowest profit margins. Soda has by far the highest. 'We at McDonald's are thankful', a top executive once told the *New York Times*, 'that people like drinks with their sandwiches.' Today McDonald's sells more Coca-Cola than anyone else in the world. The fast food chains purchase Coca-Cola syrup for about $4.25 a gallon. A medium Coke that sells for $1.29 contains roughly 9 cents' worth of syrup. Buying a large Coke for $1.49 instead, as the cute girl behind the counter always suggests, will add another 3 cents' worth of syrup – and another 17 cents in pure profit for McDonald's.

'Liquid Candy', a 1999 study by the Center for Science in the Public Interest, describes who is not benefiting from the beverage industry's latest marketing efforts: the nation's children. In 1978, the typical teenage boy in the US drank about 7 ounces of soda every day; today he drinks nearly three times that amount, deriving 9 per cent of his daily caloric intake from soft drinks. Soda consumption among teenaged girls has doubled within the same period, reaching an average of 12 ounces a day. A significant number of teenage boys are now drinking five or more cans of soda every day. Each can contains the equivalent of about ten teaspoons of sugar. Coke, Pepsi, Mountain Dew and Dr Pepper also contain caffeine. These sodas provide empty calories and have replaced far more nutritious beverages in the American diet. Excessive soda consumption in childhood can lead to calcium deficiencies and a greater likelihood of bone fractures. Twenty years ago, teenage boys in the US drank twice as much milk as soda; now they drink twice as much soda as milk. Soft-drink consumption has also become commonplace among American toddlers. About one-fifth of the nation's one- and two-year-olds now drink soda. 'In one of the most despicable marketing gambits', Michael Jacobson, the author of 'Liquid Candy' reports, 'Pepsi, Dr Pepper and Seven-Up encourage feeding soft drinks to babies by licensing their logos to a major maker of baby bottles, Munchkin Bottling, Inc.' A 1997 study published in the *Journal of Dentistry for Children* found that many infants were indeed being fed soda in those bottles.

The school marketing efforts of the large soda companies have not gone entirely unopposed. Administrators in San Francisco and Seattle have refused to allow any advertising in their schools. 'It's our responsibility to make it clear that schools are here to serve children, not commercial interests', declared a member of the San Francisco Board of Education. Individual protests have occurred as well. In March of 1998, 1200 students at Greenbrier High School in Evans, Georgia, assembled in the school parking lot, many of them wearing red and white clothing, to spell out the word 'Coke'. It was Coke in Education Day at the school, and a dozen Coca-Cola executives had come for the occasion. Greenbrier High was hoping for a $500 prize, which had been offered to the local high school that came up with the best marketing plan for Coca-Cola discount cards. As part of the festivities, Coke executives had lectured the students on economics and helped them bake a Coca-Cola cake. A photographer was hoisted above the parking lot by a crane, ready to record the human C-O-K-E for posterity. When the photographer started to take pictures, Mike Cameron – a Greenbrier senior, standing amid the letter *C* – suddenly revealed a T-shirt that said 'Pepsi'. His act of defiance soon received nationwide publicity, as did the fact that he was immediately suspended from school. The principal said Cameron could have been suspended for a week for the prank, but removed him from classes for just a day. 'I don't consider this a prank', Mike Cameron told the *Washington Post*. 'I like to be an individual. That's the way I am.'

Most school advertising campaigns are more subtle than Greenbrier High's Coke in Education Day. The spiralling cost of textbooks has led thousands of American school districts to use corporate-sponsored teaching materials. A 1998 study of these teaching materials by the Consumers Union found that 80 per cent were biased, providing students with incomplete or slanted information that favoured the sponsor's products and views. Procter & Gamble's *Decision Earth* programme taught that clear-cut logging was actually good for the environment; teaching aids distributed by the Exxon Education Foundation said that fossil fuels created few environmental problems and that alternative sources of energy were too expensive; a study guide sponsored by the American Coal Foundation dismissed fears of a greenhouse effect, claiming that 'the earth could benefit rather than be harmed from increased carbon dioxide'. The Consumers Union found Pizza Hut's Book It! Program – which awards a free Personal Pan Pizza to children who reach targeted reading levels – to be 'highly commercial'. About 20 million elementary school students participated in Book It! during the 1999–2000 school year; Pizza Hut recently expanded the programme to include a million preschoolers.

Lifetime Learning Systems is the nation's largest marketer and producer of corporate-sponsored teaching aids. The group claims that its publications are used by more than 60 million students every year. 'Now you can enter the classroom through custom-made learning materials created with your specific marketing objectives in mind', Lifetime Learning said in one of its pitches to corporate sponsors. 'Through these materials, your product or point of view becomes the focus of discussions in the classroom', it said in another, '… the centerpiece in a dynamic process that generates long-term awareness and lasting attitudinal change.' The tax cuts that are hampering America's schools have proved to be a marketing bonanza for companies like Exxon, Pizza Hut and McDonald's. The money that these corporations spend on their 'educational' materials is fully tax-deductible.

The fast food chains run ads on Channel One, the commercial television network whose programming is now shown in classrooms, almost every school day, to 8 million of the nation's middle, junior and high school students – a teen audience 50 times larger than that of MTV. The fast food chains place ads with Star Broadcasting, a Minnesota company that pipes Top 40 radio into school hallways, lounges and cafeterias. And the chains now promote their food by selling school lunches, accepting a lower profit margin in order to create brand loyalty. At least 20 school districts in the US have their own Subway franchises; an additional 1500 districts have Subway delivery contracts; and nine operate Subway sandwich carts. Taco Bell products are sold in about 4500 school cafeterias. Pizza Hut, Domino's and McDonald's are now selling food in the nation's schools. The American School Food Service Association estimates that about 30 per cent of the public high schools in the US offer branded fast food. Elementary schools in Fort Collins, Colorado, now serve food from Pizza Hut, McDonald's and Subway on special lunch days. 'We try to be more like the fast food places where these kids are hanging out', a Colorado school administrator told the *Denver Post*. 'We want kids to think school lunch is a cool thing, the cafeteria a cool place, that we're "with it", that we're not institutional…'

The new corporate partnerships often put school officials in an awkward position. The Coca-Cola deal that DD Marketing negotiated for Colorado Springs

School District 11 was not as lucrative as it first seemed. The contract specified annual sales quotas. School District 11 was obligated to sell at least 70,000 cases of Coca-Cola products a year, within the first three years of the contract, or it would face reduced payments by Coke. During the 1997–1998 school year, the district's elementary, middle and high schools sold only 21,000 cases of Coca-Cola products. Cara DeGette, the news editor of the *Colorado Springs Independent*, a weekly newspaper, obtained a memorandum sent to school principals by John Bushey, a District 11 administrator. On 28, September 1998, at the start of the new school year, Bushey warned the principals that beverage sales were falling short of projections and that as a result school revenues might be affected. Allow students to bring Coke products into the classrooms, he suggested; move Coke machines to places where they would be accessible to students all day. 'Research shows that vendor purchases are closely linked to availability', Bushey wrote. 'Location, location, location is the key.' If the principals felt uncomfortable allowing kids to drink Coca-Cola during class, he recommended letting them drink the fruit juices, teas and bottled waters also sold in the Coke machines. At the end of the memo, John Bushey signed his name and then identified himself as 'the Coke dude'.

Bushey left Colorado Springs in 2000 and moved to Florida. He is now the principal of the high school in Celebration, a planned community run by The Celebration Company, a subsidiary of Disney.

Part IV

Localized Food Systems

16

Coming in to the Foodshed

Jack Kloppenburg, Jr, John Hendrickson and G. W. Stevenson

For virtually everyone in the North and for many in the South, to eat is to participate in a truly global food system. In any supermarket here in Madison, Wisconsin, we can find tomatoes from Mexico, grapes from Chile, lettuce from California, apples from New Zealand. And, in what we take to be an indicator of a developing slippage between the terms 'sustainable' and 'organic', we can even buy organic blackberries from Guatemala (which may be organically produced, but in all likelihood are not sustainably produced if sustainable is understood to encompass more than on-farm production practices and any reasonable element of social justice). We cannot, however, count on finding Wisconsin-grown tomatoes, grapes, lettuce, strawberries or apples in any supermarket in Madison, even when those crops are in season locally.

That food in the US travels an average of 1300 miles and changes hands half a dozen times before it is consumed (*The Packer*, 1992) is deeply problematic. What is eaten by the great majority of North Americans comes from a global everywhere, yet from nowhere they know in particular. The distance from which their food comes represents their separation from the knowledge of how and by whom what they consume is produced, processed and transported. If the production, processing and transport of what they eat is destructive of the land and of human community – as it very often is – how can they understand the implications of their own participation in the global food system when those processes are located elsewhere and so are obscured from them? How can they act responsibly and effectively for change if they do not understand how the food system works and their own role within it?

Recognizing the ecological and social destructiveness of the globally based food system, a variety of analysts have suggested an alternative founded on respect for the integrity of specific socio-geographic places (Herrin and Gussow, 1989; Kneen, 1989; Berry, 1992; Crouch, 1993; Dahlberg, 1993; Friedmann, 1993; Gussow, 1993). Counterposed to the global food system in such analyses are self-reliant

Reprinted from Kloppenburg J, Hendrickson J and Stevenson G W. 1996. Coming in to the foodshed. In Vitek W and Jackson W (eds). *Rooted in the Land: Essays on Community and Place*. Yale University Press, Haven and London, pp113–123.

locally or regionally based food systems comprising diversified farms that use sustainable practices to supply fresher, more nutritious foodstuffs to small-scale processors and consumers to whom producers are linked by the bonds of community as well as economy. The landscape is understood as part of that community, and human activity is shaped to conform to knowledge and experience of what the natural characteristics of that place do or do not permit.

We find this vision of people living well and responsibly with one another and with the land on which they are placed to be deeply appealing. In our effort to work toward realization of that vision, we have found the notion of the foodshed to be particularly useful in helping us to analyse the existing food system, to imagine the shapes an alternative might take and to guide our actions. It is our purpose in this essay to elaborate and extend that concept and to share out initial understandings of its utility.

The term 'foodshed' was coined as early as 1929 (Hedden, 1929), but we were introduced to it by an encounter with the article 'Urban foodsheds', written by Arthur Getz (1991). The idea of a foodshed immediately triggered a wide range of unexpected insights and evocative associations. The intrinsic appeal the term had and continues to have for us derives in part from its relation to the rich and well-established concept of the watershed. How better to grasp the shape and the unity of something as complex as a food system than to graphically imagine the flow of food into a particular place? Moreover, the replacement of 'water' with 'food' does something very important: it connects the cultural ('food') to the natural ('shed'). The term 'foodshed' thus becomes a unifying and organizing metaphor for conceptual development that starts from a premise of the unity of place and people, of nature and society.

The most attractive attribute of the idea of the foodshed is that it provides a bridge from thinking to doing, from theory to action. Thinking in terms of foodsheds implies development of what we might call foodshed analysis, the posing of particular kinds of questions and the gathering of particular types of information or data. And foodshed analysis ought in turn to foster change. Not only can its results be used to educate, but we believe that the foodshed – no less than Gary Snyder's watershed – is a place for organizing. In this unstable postmodern world, the foodshed can be one vehicle through which we reassemble our fragmented identities, re-establish community and become native not only to a place but to each other.

In expanding on these points we will depart from Getz's usage in one significant way. Getz defines the foodshed as 'the area that is defined by a structure of supply' and notes that 'our most rudimentary map of a foodshed might cover the globe' (Getz, 1991, p26). We want to establish an analytic and normative distinction between the global food system that exists now and the multiplicity of local foodsheds that we hope will characterize the future. Since we give the term 'foodshed' this normative meaning, 'global foodshed' is for us an oxymoron. Within the existing food system there already exist alternative and oppositionalist elements that could be the building blocks for developing foodsheds: food policy councils, community-supported agriculture, farmers' markets, sustainable farmers, alternative consumers. We will use the term 'foodshed' to refer to the elements and properties of that preferred, emergent alternative.

A Foodshed in a Moral Economy

Where are we now? We are embedded in a global food system structured around a market economy that is geared to the proliferation of commodities and the destruction of the local. We are faced with transnational agribusinesses whose desire to extend and consolidate their global reach implies the homogenization of our food, our communities and our landscapes. We live in a world in which we are ever more distant from one another and from the land, so we are increasingly less responsible to one another and to the land. Where do we go from here? How can we come home again?

There can be no definitive blueprint for the construction of some preferred future Accordingly, we offer the foodshed not as a manifesto but as a conceptual vocabulary not as a doctrine but as a set of principles. Below we set out five principles that seem particularly important to us. We do not claim that these are either exhaustive or particularly original. We have drawn inspiration and insight from a wide variety of people whom we consider to be engaged – whether they know it or not – in foodshed work. We invite others to join in that work.

Moral Economy

A foodshed will be embedded in a moral economy that envelops and conditions market forces. The global food system operates according to allegedly 'natural' rules of efficiency, utility maximization, competitiveness and calculated self-interest. The historical extension of market relations has deeply eroded the obligations of mutuality, reciprocity and equity that ought to characterize all elements of human interaction. Food production today is organized largely with the objective of producing a profit rather than with the purpose of feeding people. But human society has been and should remain more than a marketplace. E. P. Thompson (1966, p203) describes a 'moral economy' as exchange 'justified in relation to social or moral sanctions, as opposed to the operation of free market forces'. Wendell Berry (1993, p14) points to similar ethical precepts when he writes of the need for 'social and ecological standards' to guide us toward the aims of human freedom, pleasure and longevity. The term 'moral economy' resonates for us and we use it here as a provisional shorthand phrase for the re-embedding of food production primarily within human needs rather than within the economist's narrow 'effective demand' (demand backed by ability to pay).

Adopting the perspective of the moral economy challenges us to view food as more than a commodity to be exchanged through a set of impersonal market relationships or a bundle of nutrients required to keep our bodies functioning. It permits us to see the centrality of food to human life as a powerful template around which to build non-market or extra-market relationships among persons, social groups and institutions who have been distanced from one another. The production and consumption of food could be the basis for the reinvigoration of familial, community and civic culture. We are all too well aware of the difficulty that will be involved in realizing this most fundamental principle of the foodshed. Nevertheless, we are encouraged by such innovations as community-supported agriculture (CSA) – 'partnerships of mutual commitment' between farmers and consumers (Van En and Roth, 1993). In CSA we have a concrete example of economic exchanges conditioned by pleasure, friendship, aesthetics, affection, loyalty, justice and reciprocity in addition to the factors of cost (not price) and quality.

The Commensal Community

CSA also serves as an illustration of our expectation that the moral economy of a foodshed will be shaped and expressed principally through communities. In *The Left Hand of Darkness* novelist, Ursula Le Guin (1969), imagines a society whose basic social unit is the Commensal Hearth. The word 'commensal' (from the Latin *mensa*, table) refers to those who eat together, and the word 'commensalism' is used in ecology to designate a relationship between two kinds of organisms in which one obtains food from the other without damaging it. We imagine foodsheds as commensal communities that encompass sustainable relationships both between people (those who eat together) and between people and the land (obtaining food without damage).

In human terms, building the commensal community means establishment or recovery of social linkages beyond atomistic market relations through the production, exchange, processing and consumption of food. Such social construction will occur among producers, between producers and consumers, and among consumers. Witness the recent proliferation of small-scale cooperative and collective production and marketing strategies implemented by farmers to meet growing consumer interest in organic, locally grown, non-industrial food. Other examples of such non-market cooperation from the upper Midwest include the mutual assistance commitments made within associations of small-scale producers of specialty cheeses, and the information and technology exchange that occurs through networks of farmers experimenting with the rotational grazing of dairy animals as an alternative to conventional, capital-intensive, confinement milk production systems (Hassanein and Kloppenburg, 1994). With respect to new relationships between producers and consumers, emerging cooperative linkages between fresh vegetable growers and neighbourhood restaurants and consumer coops parallel the birth of CSA and the revitalization of farmers' markets (Waters, 1990; Hendrickson, 1994). Among consumers themselves, buying clubs, community gardens and changing patterns of food purchase reflect growing concern with the social, economic, ethical, environmental, health and cultural implications of how they eat.

While concrete precursors of what could conceivably become commensal communities are now visible, commitment to a moral economy requires that we work to make those communities as inclusive as possible. The sustainable agriculture movement has so far tended to be 'farm-centric' (Allen and Sach, 1991, p587) 'and has not yet seriously engaged issues of race, class, and gender even within – much less outside – rural areas'. Hunger in the city is indeed an agricultural issue (Ashman et al, 1993; Clancy, 1993). The commensal community should confront and address the need not just for equitable access to food but also for broader participation in decision making by marginalized or disempowered groups. That progress is possible is evidenced by the activities of the Hartford Food System, which has made a priority of linking farmers directly to low-income consumers (Winne, 1994) and by initiatives to foster the acceptance of food stamps at farmers' markets. The 'food policy councils' now being created in a variety of US and Canadian cities are indicators of the plausibility of addressing foodshed issues by relating food affairs to other fundamental community dimensions such as economic development and nutrition and public health (Dahlberg, 1993; Toronto Food Policy Council, 1993).

Finally, the standards of a commensal community require respect and affection for the land and for other species. It is through food that humanity's most intimate and essential connections to the Earth and to other creatures are expressed and consummated. In the commensal community, production, processing, distribution, consumption and waste disposal will be organized so as to protect and, where necessary, to regenerate the natural resource base. Responsible stewardship will involve sustainable cropping and humane livestock practices, reduced use of non-renewable energy sources and a commitment to recycling and reuse.

Self-protection, Secession and Succession

The dominant dynamics of the global food system actively erode both moral economy and community. We agree with those who believe that this destructiveness is an inherent property of that system and that what is needed is fundamental transformation rather than simple reform (Allen and Sachs, 1991; Orr, 1992; Berry, 1993; Friedmann, 1993). Still, given the current dominance of the existing world food economy, people working toward foodshed objectives will need to carve out insulated spaces in which to maintain or create alternatives that will eventually bring substantive change. In opposition to the extension of the market system, there have always been examples of what Friedmann (1993, p218) calls 'movement(s) of self-protection'. From the Luddites of 19th century Britain to the Zapatistas of contemporary Chiapas, we have seen continuous refusal to submit without contest to the dictates of the globalizing food system. At the margins of consumer society and in the interstices between McDonald's and Monsanto and Philip Morris are all manner of alternative producers and eaters – Amish, vegetarians, rotational graziers, seed savers, food coop members, perennial polyculturists, bioregionalists, home gardeners, biodynamicists – who are producing and reproducing a rich set of alternative agrofood possibilities.

What these diverse people and groups share is that their activities and commitments involve various degrees of disengagement from the existing food system and especially from the narrow commodity and market relations on which it is based. We follow Berry (1993, pp17–18) and Orr (1992, p73) in our conviction that a fundamental principle of the foodshed is the need for 'secession'. This principle is based on a strategic preference for withdrawing from and/or creating alternatives to the dominant system rather than challenging it directly. Certainly, in many circumstances direct opposition to elements of the global food economy is appropriate and necessary (the situation in Chiapas, or the current manipulation of the Green Bay Cheese Exchange by food corporations such as Kraft and Pizza Hut). A primary strategy of the secession principle is 'slowly hollowing out' (Orr, 1992, p73) the structures of the global food system by reorganizing our own social and productive capacities. This is essentially what grazier groups are engaged in as they rediscover their own, indigenous capacity for producing the knowledge they need to be 'grass farmers', and as they withdraw from the agribusiness firms and agricultural scientists who have been doing their thinking for them (Hassanein and Kloppenburg, 1994).

A second and corollary point is that of 'succession', or the conscious and incremental transfer of resources and human commitments from old food-associated relationships and forms to new ones. Neither people nor institutions are generally willing or prepared to embrace radical change. The succession principle finds expression in a strategy of 'slowly moving over' from the food system to the foodshed. Food presents people with hundreds of small opportunities to take increasingly important steps away from the global market economy and toward the moral economy. An example is the consumer who decides not to purchase milk produced using recombinant bovine growth hormone (rBGH). While the motivation for that initial, simple step may be narrowly based on personal health considerations, the potential is there for making further connections. Once the link between rBGH and Monsanto is made, the consumer may become aware of the corporate/chemical/food link more generally and begin moving a progressively higher percentage of the household food budget into purchases from alternative food sources. Similarly, restaurants or schools may be encouraged to purchase more of their food supplies from local producer cooperatives as these foodshed alternatives generate capacity.

Proximity (Locality and Regionality)

We see certain key spatial components to the secession and succession dynamics as characterizing the foodshed. If mitigation of the deleterious effects of distancing is the central challenge posed by the operation of the global food system, then greater attention to proximity – to that which is relatively near – should be an appropriate response. But apart from the principle of relative proximity, it is not clear precisely where the revised boundaries ought to be drawn. The limits of a foodshed will be a function of the shapes of multiple sets of boundaries; that is, of the aggregated boundaries of the climatic features, plant communities, soil types, ethnicities, cultural traditions, culinary patterns and the like, of which foodsheds are composed. Hence we identify proximity rather than locality or regionality per se as a fundamental principle of the foodshed. Though their precise boundaries will rarely be sharply defined, we insist that foodsheds are socially, economically, ethically and physically embedded in particular places.

We do not, however, imagine foodsheds as isolated, parochial entities. While they might be – in Marge Piercy's (1976) term – as 'ownfed' as possible, we see them as self-reliant rather than self-sufficient. Self-reliance implies the reduction of dependence on other places but does not deny the desirability or necessity of external trade relationships (Friedmann, 1993, p228; Gussow, 1993, p14). For too long, however, trade in the global food economy has meant farmers selling low-value commodities to distant markets and processors and the subsequent reimportation of finished food products at high prices. In the foodshed, efforts would be made to increase the level of local and intra-regional food production, processing and distribution and so to retain economic value and jobs. Since economic concentration is a prime engine of distancing, secessionist and successionist alternatives ought to be built around small and mid-sized enterprises (dairies, cheese factories, smithies, greenhouses, canneries, restaurants, specialty markets) capable of responding affirmatively to the opportunities and responsibilities of the emergent commensal community.

The self-reliance associated with proximity is closely linked to both social and environmental sustainability. A community that depends on its human neighbours, neighbouring lands and native species to supply the majority of its needs must ensure that the social and natural resources it utilizes to fulfil those needs remain healthy. A consequence of proximate self-reliance is that social welfare, soil and water conservation, and energy efficiency become issues of immediate practical concern. For example, it is difficult for most city dwellers to be concerned about preserving farmland unless the destruction of farmland directly affects their food supply, or unless they know and care for the paving over of the land. Awareness of and affection for one's place can forestall the ethical distancing so characteristic of the global food system. In the foodshed, collective responsibility for stewardship of people and of the land becomes a necessity rather than an optional virtue.

Nature as Measure

We understand the foodshed to be a socio-geographic space – human activity embedded in the natural integument of a particular place. That human activity is necessarily constrained in various ways by the characteristics of the place in question.

Ignoring those natural constraints or overriding them with technology is one of the besetting sins of the global food system, the ecological destructiveness of which is now unambiguously apparent even to its apologists. In the foodshed, natural conditions would be taken not as an obstacle to be overcome but as a measure of limits to be respected.

While restraints on human activity will indeed often be required, to interpret natural parameters in terms of 'deficiency' rather than 'capacity' is to fail to transcend the conventional industrial mindset. Nature may be understood not just as a set of limits but as an exemplar of the possible, as an almanac of potential models for human conduct and action (Jackson, 1980; Orr, 1992, p33; Quinn, 1993). For example, from the perspective of the foodshed, one answer to Berry's (1987, p146) query, 'What will nature help us do here?' points toward the development of regional palates based on 'moving diets' of locally and seasonally available food. Who knows what lessons nature may offer us should we free ourselves to see its 'capacity'? These opportunities are by no means obvious. They must be discovered in intimate, extended conversation with the land. By acting with respect and affection for the natural world, we may begin to produce and eat *in* harmony with and within the rhythms and patterns of the places in which we live.

Ironically, much foodshed analysis will necessarily involve examination and explication of the structure and dynamics of the existing global food system. That food system exists and is a powerful and dominating structure indeed. Secession – even for so solitary a group as the Amish – can now be only partial and contingent. Emergent elements of what might become foodsheds are presently embedded in and often constrained by the rules, interests and operations of regional and global actors and institutions.

Aldo Leopold (1970, p137) suggested that we need to learn to 'think like a mountain'; that is, to think ecologically, to engage the hidden and unlooked-for connections among the elements of a system or between different levels of a system. Until and unless we know where we are in the larger social and political ecology of the global food system, we may not be able to move effectively toward realization of a foodshed locally. We do not necessarily have to accept the demands of the global food system, but we must understand and realistically address the constraints it imposes if we are to identify the space it permits for secessionist activities or simple self-protection.

Foodshed analysis will not eschew engagement with issues at the national or even the global level. It will ask that this extra-local investigation serve the objective of framing the prospects for successfully implementing concrete initiatives or changes within a particular socio-geographic place. Foodshed analysis will involve investigation of the existing food system in order to inform strategic decisions regarding opportunities for self-protection and secession. Such analysis should include the identification, celebration and study of existing and emergent alternatives to the food system. Ultimately foodshed work should seek to link such elements in a system of mutual support and integration, with the objective of fostering emergence of a truly alternative system: the foodshed. While as a general rule it is advisable to think and act as proximately as we can, we must recognize that the appropriate and necessary locus of both thought and action in the foodshed may sometimes be regional, national or even global.

Concretely, what would foodshed analysis entail? In simplest terms, it means answering Getz's basic question, 'Where is our food coming from and how is it getting to us?' For us, a substantial part of the appeal of the term 'foodshed' has to do with the graphic imagery it evokes: streams of foodstuffs running into a particular locality, their flow mediated by the features of both natural and social geography. Measuring the flow and direction of these tributaries and documenting the many quantitative and qualitative transformations that food undergoes as it moves through time and space toward consumption is the central methodological task of foodshed analysis.

What unit of analysis is appropriate for such study; what, after all, are the boundaries of a foodshed? What kinds of data or information ought to be collected? Answers to these questions will vary as a function of who is engaging in the analysis and what their objectives and resources are. The foodshed is not a determinate thing; foodshed analysis will be similarly variable. It may involve collection of data on local exports of corn or the capacity of the local landfill, on the distribution of edible plant species or the patterns of human hunger, on the organization of harvest festivals or the composition of the county board, on the content of school lunch menus or the forage preferences of diary cows.

Foodshed analysis will not be constructed to conform to some predetermined theoretical and methodological framework, but will be constituted by the concrete activities of those who seek to learn about the food system in order to change it. Many such projects have been completed or are under way at a variety of levels. The Cornucopia Project, organized by Rodale Press in Pennsylvania in the 1980s, chose states as its unit of analysis and emphasized collection of aggregate state-level data suited to the project's objective of raising the general public's awareness of the vulnerabilities of the national food system through state-specific reports and publicity (Rodale, 1982; Rural Wisconsin Cornucopia Task Force, 1982). Also at the state level, several studies by nutritionists have been undertaken in order to explore the parameters and implications for human health of sustainable, regional diets (Herrin and Gussow, 1989; Hamm, 1993).

Using cities as their socio-geographic framework, a variety of 'food policy councils' have been created to address issues of sustainability and equity in the food system (Hartford Food System, 1991; Dahlberg, 1993; Toronto Food Policy Council, 1993). The students and staff at several colleges have taken their own institutions as the basic unit of analysis and explored the rationale and mechanisms for getting commitments from their colleges to buy local food (Bakko and Woodwell, 1992; Valen, 1992). Local food projects at Hendrix College in Arkansas and Saint Olaf and Carleton colleges in Minnesota were successful in reorienting food purchasing patterns to more proximate sources. The degree of resolution characteristic of the lens of foodshed analysis can become very fine grained indeed. One of the most impressive and revealing analyses we have encountered is a self-study of a personal foodshed – 'from gut to ground' (Peterson, 1994) – that explores individual consumption and its implications for personal responsibility in the global food system.

An example of foodshed analysis that focuses on the urban poor is an initiative undertaken under the auspices of the Southern California Interfaith Hunger Coalition (IHC). The IHC's report, *Seeds of Change: Strategies for Food Security for the Inner City*, is an ambitious and finely realized effort to take an 'integrated, whole-systems approach' to assessing the need and prospects for reforming the existing food system in a specific and delimited place (Ashman et al, 1993). The IHC document is also of interest because the research and analysis for the report was undertaken largely by students and faculty from the University of California at Los Angeles. Much criticism has been directed toward universities (especially toward the land-grant colleges) for their subservience to industrial interests and their failure to orient knowledge production to local or regional needs.

Seeds of Change is striking evidence that academics can work effectively with advocacy groups oriented to transformation of the food system.

Although few of those whose efforts we have described think of what they do as 'foodshed analysis', we feel they are moving in directions similar to ours. To the extent that these diverse projects and undertakings are complementary, they constitute a rich set of conceptual and methodological resources for thinking about and assessing the nature and structure of the global food system in which we are now embedded, and for helping us to consider how and where we can realistically expect to make changes.

Radical Reformism

It is apparent to increasing numbers of people that fundamental changes are needed in the global food system. Of course, we see that the question of food is simply a specific case of the general failure of late capitalism, or post-industrialism or post-modernism or whatever you wish to call this period of intense commodification and of accelerating distancing from one another and from the Earth. We could equally well be calling for fundamental changes in the global health system, the global industrial system, the global political system, the global monetary system or the global labour system. Ultimately, what sustainability requires of us is change in global society as a whole. We need the recovery and reconstitution of community generally, not simply in relation to food. Although we may strive to think like mountains, we must act as human beings. To start the global task to which we are called, we need a specific place to begin, a specific place to stand, a specific place to initiate the small, reformist changes that we can only hope may some day become radically transformative.

We start with food. Given the centrality of food in our lives and its capacity to connect us materially and spiritually to one another and to the Earth, we believe that it is an appropriate place to begin. We offer the term 'foodshed' to encompass the physical, biological, social and intellectual components of the multidimensional space in which we live and eat. We understand the foodshed as a framework for both thought and action. If our use of the term has any virtue, perhaps it is to help people see the relatedness of apparently disparate elements, and to perceive the complementarity of different but parallel initiatives for change. We also think it useful to make a semantic distinction between where we are now and where we wish to be in the future. Thinking and acting in terms of the foodshed is an indication of our commitment to work not simply to reform the food system but to transcend that system entirely. And while a system can be anywhere, the foodshed is a continuous reminder that we are standing in a specific place; not anywhere, but here.

We need to keep place firmly in our minds and beneath our feet as we talk and walk our way toward a transformed future. Because the path is long and because we must build it as we go – the foodshed offers a project, not a blueprint – our actions will be 'slow small adjustments in response to questions asked by a particular place' (Berry, 1990, p121). We share Orr's (1992, p1) hope for 'a rejuvenation of civic culture and the rise of an ecologically literate and ecologically competent citizenry who understand global issues, but who also know how to live well in their places'. If we are to become native to our places, the foodshed is one way of envisioning that beloved country.

Farm Costs and Food Miles: An Assessment of the Full Cost of the UK Weekly Food Basket

J. Pretty, A. S. Ball, T. Lang and J. I. L. Morison

Evaluating Farm and Food Systems in Industrialized Countries

Recent years have seen growing concern about the sustainability of agricultural and food systems and the unintended side effects that can be imposed on environment and human health (Conway and Pretty, 1991; Pretty, 1995, 2002; NRC, 2000; Uphoff, 2002; Lang and Heasman, 2004). There are many perspectives on what constitutes sustainability and how it can be applied equally across agricultural contexts (Naess, 1992; Dobson, 1999; Pretty et al, 2003a). As a result, a variety of analytical approaches have been developed, including energy accounting (Leach, 1976; Cormack and Metcalfe, 2000; Carlsson-Kanyama et al, 2003), economic valuation of non-marketed goods and services (Pearce and Turner, 1990; Daily, 1997; Costanza et al, 1997; Pretty et al, 2000, 2001), ecological footprints (Rees, 2003), carbon accounting (Smith and Smith, 2000; Lal et al, 2004) and the use of indicators for sustainability (Lewis et al, 1997; Bailey et al, 1999; OECD, 1998; MAFF, 2000; Caporali et al, 2003).

Most of these approaches have focused on environmental impacts up to the farm gate and have not assessed the additional environmental effects of transporting foodstuffs via processing to retail outlets and then to the point of consumption. Evidence is mounting that these farm to plate transport costs, or 'food miles' (Raven and Lang, 1995; Subak, 1999; Jones, 2001; Pirog et al, 2001; Garnett, 2003; Stephens et al, 2003), could be substantial. In addition, there is growing interest in local and regionalized food supply systems and the potential social and environmental benefits they could bring (Marsden et al, 2000; Cowell and Parkinson, 2003; Morris and Buller, 2003; Sage, 2003; Winter, 2003).

Reprinted from *Food Policy*, 30(1), Pretty J, Lang T, Morison J, Ball A S. 2005. Farm costs and food miles: An assessment of the full cost of the UK weekly foods basket, pp1–20.

In this study, we assess the full cost of the UK weekly food basket by analysing the environmental costs to the farm gate for each major food commodity and the additional environmental costs of transporting foods to retail outlets and then to consumers' homes, and the cost of disposal of wastes. We then develop various production and transport scenarios to assess the best cost-avoidance options, and indicate where policy priorities should lie in the light of the findings.

The externalities arising from farm and food systems point to some important policy priorities for industrialized countries in Europe, North America and the OECD, where there are many similarities in both farm technologies and distribution systems for food. Important drivers that may differ from country to country include the quality and types of food eaten (as costs vary greatly according to commodity), the amount of farm inputs used that result in external costs, the average distance travelled by food from farm to plate and the proportion of foods imported that impose externalities in other countries, thereby effectively exporting costs (Lang and Heasman, 2004). Some of these costs could be avoided with the adoption of more sustainable farming and food distribution systems.

The external benefits of agricultural systems include a wide range of unpriced goods and services, such as recreation and amenity value of landscapes, water holding capacity, carbon sequestration, wildlife and biodiversity and contributions to rural economies and communities (Bollman and Bryden, 1997; Pretty, 2002, 2004; Renwick et al, 2002; Dobbs, 2004). We do not address here the contributions that agricultural and land use systems make to positive externalities and so do not seek to make any cost–benefit comparisons. There is a danger that this will appear to bias our analysis against modern agriculture. These positive side effects are known to be substantial: for example, some 550 million day-visits are made to the countryside each year by urban people who derive value and pleasure from the farmed landscape. However, no study has yet put an aggregate value on the positive externalities. In this study, we therefore do not make any judgement about the comparative differences in contribution that conventional and organic farms make to positive externalities.

Environmental Costs to the Farm Gate

The environmental costs of farming have been recently assessed for the UK (Pretty et al, 2000, 2001; Hartridge and Pearce, 2001; EA, 2002), Germany (Waibel et al, 1999) and the US (Subak, 1999; Tegtmeier and Duffy, 2004). For this study, earlier data on UK farm externalities (Pretty et al, 2000, 2001; Hartridge and Pearce, 2001; EA, 2002) were reassessed by incorporating new data on eutrophication, greenhouse gas costs, energy embodied in inputs and BSE (Renwick et al, 2002; Pretty et al, 2003b; Defra, 2004). The methods used in these studies are largely cost-based rather than demand-based and involve the use of replacement costs (e.g. hedgerows, wetlands), substitute goods (e.g. bottled water), loss of earnings (e.g. due to ill-health) and clean-up costs (e.g. removal of pesticides and nitrate from drinking water). Demand-based methods using willingness to pay (or be compensated) have tended to be used in studies to put a value on landscapes (Hanley et al, 1998).

One problem with all such studies is the difficulty of baselines and absolute costs. For example, if there were no livestock, then methane costs would be very much reduced. But if there were no agriculture, then there would still be an amenity value arising from the landscape. Thus these costs of agriculture are relative to an artificial baseline of zero. For our purposes here, the comparison between different agricultural systems (conventional and organic) provides an escape from this artificiality.

The UK studies indicate that total agricultural environmental and health costs are some £1514 million (M) for the year 2000 (35 per cent lower than originally calculated in Pretty et al, 2000). Some costs remain impossible to assess, such as antibiotic resistance arising from prophylactic use in livestock systems and the chronic health effects of pesticides, and these are not included.

In Table 17.1, we compare the external costs of the current agricultural system with those that would arise were the whole of the UK farmed with organic production systems. The choice of this scenario is not because organic is the only form of agricultural system that is more sustainable than current practices, but because it has a well-defined system of standards (EC Regulation 2092/91; FAO/WHO,

Table 17.1 *The negative externalities of UK agriculture (year 2000)*

Source of adverse effects	*Actual costs from current agriculture (£M yr^{-1})*	*Scenario: costs as if whole of UK was organic (£M yr^{-1})*
Pesticides in water	143.2	0.0
Nitrate, phosphate, soil and *Cryptosporidium* in water	112.1	53.7
Eutrophication of surface water	79.1	19.8
Monitoring of water systems and advice	13.1	13.1
Methane, nitrous oxide, ammonia emissions to atmosphere	421.1	172.7
Direct and indirect carbon dioxide emissions to atmosphere	102.7	32.0
Off-site soils erosion and organic matter losses from soils	59.0	24.0
Losses of biodiversity and landscape values	150.3	19.3
Adverse effects to human health from pesticides	1.2	0.0
Adverse effects to human health from micro-organisms and BSE	432.6	50.4
Totals	£1514.4	£384.9

Sources: Adapted from Pretty et al, 2000; Hartridge and Pearce, 2001; EA, 2002

2001; IFOAM, 2000). Organic agriculture is a defined and certified system of agricultural production that seeks to promote and enhance ecosystem health whilst minimizing adverse effects on natural resources. It is seen not just as a modification of existing conventional practices, but as a restructuring of whole farm systems (Lampkin and Padel, 1994; FiBL, 2000; Scialabba and Hattam, 2002; Caporali et al, 2003; Reganold, 2004). In 2003, there were 4104 organic farms in the UK covering some 741,000ha (Defra, 2003). We used standard organic protocols to estimate the contribution that would be made to total costs by each of the ten sectors listed in Table 17.1. Pesticide costs arising from drinking water contamination and adverse effects on human health are assumed to fall to zero under an organic farming regime, as are any costs associated with BSE. Most of the other sectors would see declines in costs compared with conventional farming, but not to zero. Our assumptions on these are as follows:

1 for drinking water, nitrate costs are assumed to fall by 20 per cent, phosphate and soil losses by 75 per cent, zoonoses by 20 per cent, eutrophication by 75 per cent, with monitoring costs remaining the same;
2 for gaseous emissions, methane costs from livestock are assumed to fall by 5 per cent, ammonia by 25 per cent, nitrous oxide by 80 per cent, carbon dioxide from fuel use remains the same and indirect emissions through reduced use of fertilizers and pesticides by 88 per cent;
3 for soil costs, off-site damage is assumed to fall by 20 per cent and carbon dioxide losses in organic matter by 75 per cent;
4 for biodiversity and landscape losses, costs are assumed to fall by 75 per cent for wildlife and by 90 per cent for hedgerows losses, though remain the same for bee colonies;
5 for micro-organisms and disease-agents, costs are assumed to fall by 75 per cent.

We estimated that a complete switch to organic agriculture could lead to cost-avoidance (i.e. benefits compared with current agricultural systems) of £1129M yr^{-1}.

These aggregate costs were used to calculate the costs for each of the 12 major arable, horticulture and livestock food commodities produced in the UK (cereals, potatoes, oil seed rape, sugar beet, fruit, vegetables, beef/veal, pork, poultry, mutton/lamb, milk and eggs). We assessed 19 categories of environmental costs for each of these 12 commodities and calculated the relative contribution of each commodity to each cost category. In some cases, there is only one source for a problem (e.g. BSE from cattle); in others, there are multiple sources (e.g. nitrate from crops and livestock systems). We used various Defra data sets on area devoted to each commodity, on animal numbers, on input-use and on emissions to calculate these proportional contributions from each commodity (mean values taken for 1999–2001). In the UK, there are 4.89M ha of arable and 6.67M ha of grassland (not including rough and hill grazing).

The basis for the allocations of each of the categories of negative externalities to the 12 crop and livestock commodities were as follows (see Pretty et al, 2000, 2001 for full details and references for each category):

1 Of all pesticide costs, 80 per cent were allocated in proportion to area of each arable crop and the remaining 20 per cent evenly spread across all livestock categories.
2 Nitrate costs were allocated in proportion to area of each crop commodity and grassland for livestock.
3 Phosphate and soil erosion costs were allocated mainly to arable crops (91 per cent), with an allocation to pigs for leaching (9 per cent).
4 One third of *Cryptosporidium* costs were allocated to each of milk, beef and sheep, as the pathogen does not occur in pigs or poultry.
5 Eutrophication costs were allocated in proportion to area of crops and grassland.
6 Monitoring costs were allocated in proportion to area of all crops and grass.
7 Some 89 per cent of agricultural methane emissions arise from enteric animals (75 per cent from cattle, 25 per cent from sheep), while the remaining 11 per cent arises from manures of all animals (costs are equally allocated); and thus milk is calculated to contribute 35 per cent to methane costs, beef/veal 35 per cent, mutton/lamb 25 per cent, and pork and poultry 2.5 per cent each.
8 Ammonia costs arising from livestock wastes were allocated 20 per cent each to milk, beef, pork, poultry and sheep.
9 Nitrous oxide costs were allocated in proportion to area of crops and grassland.
10 Carbon emitted from fossil fuel use (mostly for vehicles) was in proportion to area of crops and grassland, with costs adjusted up (double their proportional contribution) for pigs, poultry and eggs (owing to energy used in housing) and down by half for sheep (which are mostly outdoors).
11 Indirect energy costs arising from the manufacture of pesticides and fertilizers were allocated in proportion to the areas of crops and grassland.
12 Off-site soil erosion costs were allocated in proportion to the areas of crops and grass.
13 Organic matter carbon losses were allocated in proportion to just arable area (it is assumed that losses from grassland are negligible).
14 Biodiversity and wildlife costs were allocated in proportion to the area of crops and grassland.
15 Costs arising from losses of landscape features were allocated in proportion to area, with greater losses of hedgerows assumed to occur in arable rather than under beef/sheep.
16 Bee colony losses were proportional to just arable area.
17 The costs arising from acute pesticide adverse effects were allocated to 50 per cent for sheep dips, 40 per cent for cereals and the remainder spread amongst remaining crops.

18 Some 75 per cent of the costs to consumers from outbreaks are assumed to arise after the farm gate, and of the remaining quarter pathogenic outbreaks in food, some 90 per cent are from livestock produce and 5 per cent each from fruit and vegetables.
19 BSE and new variant CJD costs were allocated to cattle alone.

The total costs arising from the cultivation and raising of each of the 12 commodities are shown in Table 17.2, together with the unit costs per kg, litre or dozen eggs using average UK production data for 1998–2001 (Table 17.2). The same series of calculations are shown for an organic production scenario. On a per kg basis, livestock produce imposes the greatest costs: beef/veal 64.8p kg^{-1}, mutton/lamb 43.6p kg^{-1}, pork 12.8p kg^{-1}, poultry 5.68p kg^{-1}. Oil seed rape imposes the highest costs for arable and horticultural produce (3.45p kg^{-1}), followed by cereals (1.72p kg^{-1}), fruit (1.44p kg^{-1}), vegetables (0.61p kg^{-1}), potatoes (0.42p kg^{-1}) and sugar beet (0.22p kg^{-1}). Some of these external costs are a significant proportion of the price received for commodities. For example, the 1.72p kg^{-1} external cost for cereals represents a value of 17.7 per cent of the average UK price of wheat in the first half of 2004; the 3.96p dozen $eggs^{-1}$ is 6.3 per cent of average

Table 17.2 *External costs to the farm gate for 12 food commodities grown and raised in the UK*

Produce	*External costs from conventional agriculture*		*Scenario: as if whole of UK was organic*		*Proportional change in external costs from conventional to organic (%)*
	Total external cost (£ M yr^{-1})	*Unit external costs (p kg^{-1})*	*Total external cost (£ M yr^{-1})*	*Unit external cost (p kg^{-1})*

Eggs	30.3	3.96	11.3	1.44	–36.4

2003–2004 UK price; and the 0.42p kg^{-1} external cost for potatoes is 3.0 per cent of the average 2003–2004 UK price (Defra, 2004).

With these unit costs for food commodities, it is now possible to reassess the full costs of each of the components of the weekly UK food basket.

The Weekly Food Basket

The National Food Survey (NFS) and the Food Expenditure Survey (FES) (combined in 2003 as the Expenditure Food Survey) record data on weekly consumption and expenditure for each item of food in the average domestic food basket (Defra, 2002a, 2002b). On average, each person in the UK consumes in the home 10.02kg of food wk^{-1} and this costs £17.26 wk^{-1} (average for 1999–2000). In addition, individuals spend £7.53 wk^{-1} on eating out (an average of three times per week), bringing the total weekly expenditure to £24.79 (eating out is 30 per cent of food expenditure) for 11.68kg of food (see Table 17.3).

These data are obviously aggregate commodity costs for the whole of the UK and its food system. There will, however, be geographic and income-group variations according to choice of food consumed and expenditure. The average weekly food basket in Scotland is 4.4 per cent less than the UK average, 6.8 per cent less in Wales, 1.2 per cent less in Northern Ireland and 0.8 per cent more in England. The most expensive two regions of England are London at £19.53 (+10.7 per cent) and the South East at £20.35 (15.4 per cent), and the least expensive are Yorkshire and Humberside at £16.08 (–9.1 per cent) and the North East at £16.13 (–8.6 per cent). Households earning >£725 gross wk^{-1} spend £22.03 (+24.9 per cent), while those earning £180–375 spend 10.6 per cent less and those on <£180 spend 20.3 per cent less (Defra, 2002a, 2002b).

In order to relate external commodity costs (in pence kg^{-1}, p l^{-1} and p dozen $eggs^{-1}$ produced) to the environmental costs arising from the food choices made by consumers, several adjustments were made to account for losses in the supply chain and distortions arising from imbalances in imports and exports. A loss factor for each food product was calculated, as some produce is fed to animals (e.g. 73 per cent of all cereals are fed to livestock: 1.49Mt to cattle, 0.45Mt to pigs, 0.13Mt to poultry, 0.097Mt to sheep, for a total of 2.16Mt in 1999–2000), some is lost as waste, some is converted into secondary products or prepared meals (e.g. wheat to flour to bread, barley to beer) and some is disposed to landfill. Using the two national food surveys, weekly consumption data for the UK population of 59.64 M people were compared with national domestic agricultural production data to calculate a loss factor for each commodity.

In addition, further adjustments for imports and exports of foods have been made. Some of the farm externalities incurred in the UK are for food produced in the UK that is then exported and some of the food consumed is from imported produce where farm externalities are incurred in overseas agricultural systems.

Table 17.3 *Components of UK weekly food basket and expenditure per person, plus price of each component including externalities to farm gate*

Components of food basket	*Consumption (home + eating out) g person^{-1} wk^{-1}*	*Expenditure (p person^{-1} wk^{-1})*	*Price including externalities from current agriculture (p person^{-1} wk^{-1})*	*Price including externalities if all organic agriculture (p person^{-1} wk^{-1})*[1]

Notes:

1 Organic scenario does not include price premiums
2 Fish: no data on externalities costs from capture fisheries or aquaculture
3 No costs allocated for tea/coffee as grown overseas
4 Totals may not sum due to rounding.

Here we make an adjustment to account for externalities only incurred in the UK to reflect environmental costs imposed by the current agricultural and food system and its mixture of exports and imports. It is important to note, however, that individual countries could reduce the negative environmental impacts of their agricultural systems by ceasing domestic production and switching to importing food. This would not lead to net environmental benefits at the global scale if this simply displaced externalities. Alternatively, if the overseas production systems were more environmentally beneficial in comparison with domestic ones, then there may be a net environmental benefit (after transport costs were also accounted for). Here we simply take account of the current export–import patterns to reflect where domestic costs are imposed.

Using Defra data (mean 1999–2000) on imports and exports of the 12 commodities, ratios for domestic produce as a proportion of total consumption were calculated for each commodity. Only two have a ratio of <1, indicating that they are net exported (cereals 0.91, oil seed rape 0.82), the remainder varying from 1.04 for sheep products (where imports and exports are almost balanced) to 9.62 for fruit (where imports greatly exceed exports). Total annual food commodity movements are 19.6Mt, comprising 12.2Mt yr^{-1} for imports and 7.4Mt yr^{-1} for exports, of which swapped commodities (with technically the same produce both imported and exported) amount to 5.23 Mt yr^{-1}. For example, 0.48Mt of pork is imported each year, while 0.21Mt is exported; 0.41Mt of milk is imported and 0.43Mt exported; and 0.13 M sheep are exported while 0.12 M are imported. Not all this produce is entirely substitutable, as imports and exports may be of different meat cuts or different types of animal. However, it is likely that commodity transport movements could be reduced.

After adjustments for losses in the food chain and for imports–exports, costs for p kg^{-1} consumed rather than p kg^{-1} produced were calculated. These were applied to each item of food consumed in the weekly food basket, giving a total of 81.2p wk^{-1}, or an additional 3.27 per cent on the price of the weekly food basket, raising the real cost including environmental externalities to the farm gate to £25.60 (Table 17.3). In the food basket, no externalities for fish consumption were calculated, as there were no appropriate data, and none were added for overseas produce (e.g. coffee, tea) where farm externalities have not occurred in the UK. However, if this 81.2p were multiplied by the total UK population, then it would wrongly imply costs greater than the £1514 M yr^{-1} calculated for farm externalities. This is because imports to the UK are greater than exports and so externalities arising from total consumption are greater than from production alone.

The costs for a wholly organic food basket scenario were also calculated (Table 17.3). We assume that this organic food basket has the same constituents as the average UK food basket and that prices do not affect these proportions. These costs amount to an additional 19.45p in environmental costs to the farm gate, or equivalent to an extra 0.79 per cent on the price paid for the food basket. But consumers already pay a premium on organic food at most retail outlets, so their food basket already costs more than conventional food. Retail price data on each food product (Hamm et al, 2002; Ross, 2002) were used to calculate the cost of an identical but organically sourced food basket. Two sources were compared: (i) supermarkets, where the average premium is 53 per cent; and (ii) local box schemes and farm shops, where the average premium is 31 per cent. The weekly food basket would cost £39.37 if bought at a supermarket (59 per cent more than conventional) and £33.39 if bought via the local scheme (35 per cent more than conventional).

Price premiums could be justified on the grounds that they cover the additional costs incurred by organic farmers in avoiding damage to the environment (though in practice higher prices arise because of the demand for organic products relative to supply). But the difference between farm externalities for the organic compared with conventional food basket (81.2 less 19.45p = 61.75p) is very much smaller than the premium charged to consumers (£14.58 at supermarket; £8.59 at local scheme). One explanation is that retailers, manufacturers and/or farmers are charging more as they believe some consumers will pay more. The difference can only be partially explained as representing the value of on-farm natural capital being built by farmers through improvements to soils, biodiversity and landscape.

Transport to Retail Outlets

Vehicle transport imposes various environmental, social and health costs and these have been calculated for the UK in pence per vehicle km (p vkm^{-1}) for various types of vehicle and the cost categories of congestion, harm to health (noise, asthma), climate change (from greenhouse gases) and infrastructure damage (Nash and Salmon, 1999; Dodgson et al, 2002). These costs are shown in Table 17.4.

National statistics record three measures for freight transport: bn t-km travelled, Mt of goods lifted and vkm travelled, and all measures have increased in recent years (DLTR, 2002; EEA, 2003). Between 1980–1982 and 2000, bn t-km for all goods rose by 65 per cent to 149.3; Mt lifted by 23 per cent to 1580; and

Table 17.4 *Environmental and health costs (in pence) per vehicle kilometre for various modes of transport*

Vehicle type	*Costs (p per vehicle km)*
Car	11.95
Light commercial	13.71
Heavy goods vehicle (rigid)	31.57
Heavy goods vehicle (articulated)	42.92

Sources: Nash and Salmon, 1999; Dodgson et al, 2002 vkm by 41 per cent to 22.2 billion. Agrifood products (food, drink, tobacco, fertilizer) now account for 28.1 per cent, 28.1 per cent and 28.8 per cent of these totals respectively (up from an average of 25.1 per cent in 1980–1982). This is despite the fact that retail logistics are now claimed to be the most efficient in the world, with more centralized distribution centres, just-in-time stock management, factory gate pricing, information technology innovation, increased backhauling and more home deliveries (IGD, 2003; Garnett, 2003).

Adjusting for the proportion of freight transported in different size vehicles (16 per cent for 3.5–17t; 39 per cent for 17–33t; 43 per cent for >33t) (DLTR, 2002), the total externalities of movement to retail outlets of agricultural produce is calculated to be £2348 M yr^{-1}. This is equivalent to £39 $person^{-1}$ yr^{-1}, or 75.7p wk^{-1}. With farm externalities, this now increases the real cost of the weekly food basket to £26.37 (a 6.4 per cent increase).

National transport statistics already include a factor for empty running, more than a quarter (26.4 per cent) of all vehicles on the roads are recorded as running empty (DLTR, 2002). In addition, only 59 per cent of space is filled (the lading factor). Thus one tonne moved 1km effectively travels 1.69 (i.e. 1/0.59) × 1.264 = 2.14km, or each average km travelled carries only 46.7 per cent of total possible load. Thus, as 26.4 per cent of vkm are empty, some £619 M yr^{-1} of food mile costs could be avoided if vehicles were run to full capacity.

Domestic data do not include air, ship and truck transport from overseas sources. However, climate change contributed by this overseas transport does affect UK consumers and so data for carbon emissions from fossil-fuel consumption (C $t\text{-}km^{-1}$) (Gover, 1994; DLTR, 2002) and their marginal damage costs (Hartridge and Pearce, 2001) (£29.8 tC^{-1}, 2.98p per kg of carbon as C) were used to calculate additional climate change costs per t-km. A factor for congestion, health or infrastructure for overseas transport is not included, as they do not directly affect consumers in the UK.

The produce imported by sea to the UK amounts to 388 Mt yr^{-1}, of which food, drink and agricultural inputs are 18.6Mt. The costs per t-km for sea transport are 0.0082p $t\text{-}km^{-1}$ (for 2.74g C $t\text{-}km^{-1}$). Assuming a conservative average of 10,000km per trip (by ship, New Zealand is 23,000km distant, Australia 21,500km, California 16,300km, The Netherlands 100km and Denmark 1200km), then these 186bn t-km incur costs of £15.25 M yr^{-1}. These costs are very small (0.65 per cent transport of foods on domestic roads in the UK to retail outlets).

There are, however, concerns that air miles may be making a significant contribution to environmental costs. In 1998, there were 100 bn t-km of goods transported by air in 1998 worldwide (IPCC, 1999; Defra, 2001). UK airfreight (imports + exports) was 2Mt for 1998, of which imports of fruit and vegetables were only 0.114Mt yr^{-1}. For air trips, an average distance travelled of 8500km was assumed (South Africa is 9600km distant; New Zealand 18,800km; Chile 11,700km; Mexico 8900km; Zambia 7900km; Argentina 11,100km; California 8800km). With costs per t-km of 0.46p $t\text{-}km^{-1}$ (156 g C $t\text{-}km^{-1}$), then this gives a total of 0.97bn t-km and an external cost of £4.46 M yr^{-1}. If all airfreight travels in dedicated freight planes, then the full costs are incurred (every extra kg consumed requires extra space). But some airfreight is carried in the belly of passenger planes, so does not technically incur the full marginal cost – just the extra fuel required to haul the additional freight. Globally, 50% of airfreight is in the belly of passenger planes (Garnett, 2003) and so the external costs of air imports of fruit and vegetables is only £2.23 M yr^{-1}. Once again, this is trivial compared with the environmental costs of domestic transport (0.09 per cent of domestic road costs). However, it is important to note that if all of the weekly food basket were transported by air, then the additional environmental costs would become severe. It is only because of the low volume at present that these costs remain relatively low.

Transport of Food to Home and to Landfill

Once the food is at the retail outlet, consumers still have to transport it home for consumption. National statistics on shopping trips and the environmental costs of transport for cars, buses, walking and cycling were used to calculate the cost for shopping for food (Dodgson et al, 2002; Defra, 2002d). Each person in the UK made 221 shopping trips per year in 2000 (up from 210 in 1985–1986), with an average length of 6.4km (up from 4.6km), resulting in a total travel of 1414km yr^{-1} (up from 978km yr^{-1} in 1985–1986). Of these shopping trips, 58 per cent were made by car, 30 per cent by walking, 8 per cent by bus and 3 per cent cycle. The 221 trips are equivalent to 4.25 per person wk^{-1}.

Assuming that only half of trips are solely for food, and that food shopping is per household rather than per person (the food basket is per person and on average there are 2.32 persons per household), then 110.5 trips are made per household per year for food. As the average distance is 6.4km, these trips cover 706km yr^{-1} for food or 13.6km per week. Of these, 7.89km are by car (at cost of 11.95p vkm^{-1}), 1.09 are by bus (at 33.57p vkm^{-1}, but with 30 people per bus) and 4.49km are by walking and cycling (at zero cost). This gives a total cost for transport to home of 95.43p $household^{-1}$ wk^{-1}, 41.1p $person^{-1}$ wk^{-1} and an aggregate of £1275.7 M yr^{-1}.

Each person produces 74kg of domestic organic waste per year (Defra, 2002d). Each household throws away 3.29kg wk^{-1}, plus an additional 4.06kg wk^{-1} of food packaging, resulting in a total disposal of 9.8Mt yr^{-1}. As each garbage truck carries some 10t when compressed, and travels 23km from depot to pickup to landfill site (DLTR, 2001), then these loads at an environmental costs of 31.57p vkm^{-1} incur aggregate costs of £7.12 M yr^{-1} or just 0.002p $person^{-1}$ wk^{-1}.

The Issue of Subsidies

Subsidies can be seen to be part of the full cost of food, as they are payments from taxpayers to farmers. They are not externalities, but can exacerbate them by increasing output beyond that which would be dictated by market conditions. Public subsidies can be progressive, as the wealthy pay more tax than the poor, and the benefits of the subsidies are equally spread amongst food consumers (though some food production systems have not to date received public support, e.g. pigs, vegetables). Subsidies only have their full effect if they encourage the production of public goods (or positive externalities) that are available to consumers. But until 2004, formal subsidies have mostly supported agricultural production systems that give rise to adverse environmental effects and so must logically be seen as perverse. Annual support for organic farming amounted to £6–18 million per year for 1999–2000 and 2000–2001.

The average annual UK government subsidy for all agriculture in 1999–2000 and 2000–2001 was £3.102 billion (Defra, 2002c). We did not use data for 2001–2002 as this included an additional £2 bn for foot and mouth disease, giving a total of £5.26 bn. For each person in the UK, the £3102 M represents an additional cost of £52 yr^{-1}, or £1 per week. However, some £219 million of this total was used for rural development and agrienvironment schemes intended to create positive externalities (Defra, 2002c). Assuming that these are successful, we removed them from total costs to leave total subsidies of £2883 M yr^{-1}, which is equivalent to 93p $person^{-1}$ wk^{-1}.

The Full Costs and Scenarios for Cost-avoidance

Table 17.5 contains a summary of our estimates of the full costs paid by UK consumers for their food basket. The weekly food basket rises in cost from the £24.79 paid by consumers by £2.91 per person wk^{-1} (11.8 per cent), with farm externalities (81.2p), domestic road transport (75.7p), government subsidies (93p) and shopping transport (41.1p) contributing the most. Sea and air transport and transport to landfill are very small contributors to overall cost. This amounts to additional costs of £8045 million yr^{-1} to the whole food system.

This could be an underestimate of the full costs, as many environmental side effects in the food chain have not been assessed here. These include energy consumed by processors, manufacturers and wholesalers for light, heat, refrigeration and transport, disposal of food packaging, foods consumed by domestic pets, methane emissions from landfill and sewage waste, and the energy required for domestic cooking. In addition, we have not assessed the health consequences of the dietary choices made for the weekly food basket (Kenkel and Manning, 1999; Ferro Luzzi and James, 2000; Rayner, 2001; Wanless, 2004). Such diet-related ill

Table 17.5 *Summary of components of full costs of the UK food basket (average for 1999–2001)*

	Annual costs (£ M yr^{-1})	*Costs per person (p person^{-1} wk^{-1})*	*Proportion of total externalities*
Agricultural externalities	1514	81.2[1]	18.8%
Domestic road transport (from farm to shop)	2348	75.7	29.2%
Sea, internal water and air transport for imports	17	0.005	<0.01%
Shopping (from shop to home)	1276	41.1	15.8%
Waste disposed to landfill	7	0.002	<0.01%
Total externalities	5162	198	
Government subsidies	2883	93	
Price paid for food basket (including eating out)	89,500	2479	
Full cost of food basket (total externalities and subsidies)	8045	291	—
Full cost (including externalities and subsidies)	97,545	2770	—

Note: 1. The agricultural costs per person are not simply annual costs divided by population, as account has been taken of imports and exports to and from the UK.

health is costly, but clearly not a direct consequence of types of agricultural systems.

Another source of error arises from recent changes in farm practices, with many farms adopting environmentally-sensitive practices in recent years, and so our estimates of environmental costs may be too high. At the same time, transport distance to retail outlets and by shopping is increasing and so these costs may be underestimates. A further source of uncertainty arises from the comparison of organic and conventional systems, as we have relied on assumptions that certain practices would guarantee certain environmental outcomes. This may not prove to be true, for example, if organic farming were to be much more widespread than at present.

An important policy question centres on what might be done to avoid some of these costs through adoption of more sustainable methods of food production, localized food systems and more sustainable methods transport, such as substituting bus for car, ship for air, rail for road, and reducing empty running and unfilled vehicles.

We calculated the benefits of various scenarios for changes in farm practice, transport to retail outlets, transport to home and for waste disposal (Table 17.6). If the food basket were all organic and subsidies all used for agrienvironmental

Table 17.6 *Avoided costs under different scenarios for adoption of organic farming, localized food systems and more sustainable transport options*

Scenarios	*Current external costs (£M yr^{-1})*	*Revised total external costs under each scenario (£M yr^{-1})*	*Revised per capita external costs under each scenario (p $person^{-1}$ wk^{-1})*	*Avoided costs with new farm and/or transport strategies (£M yr^{-1})*
A. Farm externalities				
A1. All farms organic (from Table 17.1)	1514	385	19.5	1129
B. Transport to retail outlet				
B1. Local food system (all less than 20km)[1]	2348	229	7.4	2119
B2. National with maximized rail[2]	2348	842	27.2	1506
B3. All continental Europe[3]	2348	3374	108.8	(1026)[10]
B4. All global ship[4]	2348	2712	87.4	(364)[10]
B5. All global air[5]	2348	19,708	636.1	(17,360)[10]
C. Transport to home				
C1. Shopping all by cycle/walk[6]	1276	0	0	1276
C2. Car shopping replaced by bus[7]	1276	126	4.1	1150
C3. Car and bus replaced by home delivery[8]	1276	549	17.7	727
D. Waste				
D1. All organic material composted[9]	7	0	0	7

Notes:

1 All of food basket sourced from within 20km of retail outlet.

2 80% of food travels by rail (with zero congestion costs) and 20% by road, and that costs are 56g C t-km^{-1} by road (large truck) and 11.1 g C t-km^{-1} by rail.

3 All food sourced within continental Europe, travelling an average of 1500km, then 444Mt (at 25t carried per vehicle) would require 17.76 M vehicles to travel 26,640 M km yr^{-1}; and using an external cost of 1.8p t-km^{-1} (just climate change costs are included, as congestion, health and infrastructure damage occurs elsewhere in Europe) and multiplying by the ratio of 2.14 (for empty running and lading factor).

4 All food imported by sea and that 10,000km travelled, then 4440 billion t-km would be carried at 0.0082p t-km^{-1}.

5 All food imported by air and that 8500km travelled, then 3774 billion t-km would be carried at 0.46p t-km^{-1}.

6 Cycling and walking incur no transport externalities (we do not count the health benefits of exercise here).

7 All current car transport replaced by bus (and 33% still by walking and cycling).

8 All car and bus transport replaced by home delivery and assuming a 60km round trip once per week to 20 households, and costs for LDVs at 13.71p v-km^{-1}.

9 All organic food waste is composted at the home.

10 (brackets) indicates an increase in costs.

Table 17.7 *Comparison of various transport scenarios for conventional and organic food baskets*

	Total cost of individual food basket (price + externalities) (£ wk^{-1})	*% increase in total cost over price paid*	*Saving per person over current full costs (£ wk^{-1})*
Total current food basket costs (price + externalities arising from conventional agriculture, national and car transport, waste to landfill and subsidies)[1]	£27.71	11.8%	–
Current food basket with different transport scenarios			
+ local food + walk/cycle	£26.60	7.3%	£1.11
+ local food + home delivery	£26.78	8.0%	£0.93
+ local food + bus	£26.65	7.5%	£1.06
+ national road + car	£27.70	11.7%	£0.01
+ national rail + bus	£26.84	8.3%	£0.87
+ continental Europe + car	£28.03	13.1%	(£0.32)
+ global air + car	£33.30	34.3%	(£6.59)
All organic food basket with different transport scenarios			
+ local food + walk/cycle	£25.06	1.1%	£2.65
+ local food + home delivery	£25.24	1.8%	£2.47
+ local food + bus	£25.10	1.3%	£2.61
+ national road + car	£26.15	5.5%	£1.56
+ national rail + bus	£25.30	1.2%	£2.41
+ continental Europe + car	£26.48	6.8%	£1.23
+ global air + car	£31.76	28.1%	(£4.05)

Note: 1 From Tables 17.4 and 17.5.

purposes (as can eventually be expected following the reform of the Common Agricultural Policy), and that food were locally sourced or predominantly transported by rail and then transported home by walking/cycling, bus or home delivery, then external costs would fall from 11.8 per cent of the food basket to 1.1–1.8 per cent, saving each person in the UK £2.41–2.65 wk^{-1}. The saving would be less if the food basket was all conventional (Table 17.7). If all food were sourced within 20km of homes or other places of consumption, then we estimate that £2119 M of environmental costs would be avoided.

But if an entirely organic food basket was sourced from continental Europe and transported by current transport modes, then the avoided costs to the farm gate would be offset by the transport costs (though any farm costs would be incurred outside the UK). Furthermore, produce entirely globally sourced by air would increase the price to each person by an additional £4.05 wk^{-1} if it was organic and £6.59 wk^{-1} if conventional (Table 17.6). Some £1276 M of costs would be avoided if all food shopping were by cycle or walking; £1150 M avoided if cars were replaced with public transport; and £727 M avoided if car and bus were replaced by home delivery schemes.

These scenarios, although they are unlikely to arise entirely, do indicate the scale and relative contributions to the weekly food basket of various components of the food chain. The data suggest that degrees of local-ness might be more significant than previously considered. They also indicate that consumers' decisions on specific choices of food (here organic versus conventional) and transport can have an important affect on farm systems and the environment, and will be an important consideration in future policy reform. The data further indicate the value of domestic garden and allotment produce, as such food production incurs low to zero farm externalities and effectively zero transport externalities (allotments currently produce 0.22Mt yr^{-1} of fruit and vegetables, compared with 3.17Mt produced on farms).

Concluding Comments

We have calculated the environmental costs of the UK food basket and found that farm externalities, domestic road transport to retail outlets, domestic shopping transport and subsidies are the main contributors to the estimated hidden costs of £2.91 per person per week (11.8 per cent more than the price paid). It is clear that actions to reduce farm and food mile externalities and shift consumers' decisions on specific shopping preferences and transport choices would have a substantial impact on environmental outcomes. The potential for food and transport businesses and governments to reduce these externalities would appear to be considerable. The key policy questions now centre on how best to do this using a variety of taxation, incentive and regulatory mechanisms. It will be important to ensure that agriculture and food policy reforms continue to result in the production of safe and nutritious food whilst also maximizing the production of positive externalities.

The most likely scenario for the immediate future is 'business as usual' with some incremental change. It could be, however, that external shocks institute more radical change. Such potential shocks range from another energy or oil crisis to the realization of the seriousness of climate change or of the immense costs of current systems such as we outline here.

However, localization of food systems, such as we point to here, would require changes in the behaviour of actors and businesses across the whole supply chain, with localized geographic areas needing different patterns of land use to supply local markets and consumers. Some of these changes may lead to trade-offs and losses in overall system sustainability, or possibly losses in jobs in the freight or input supply industries. In addition, proximity alone may not be a good measure of sustainability, as a long journey on water has a lower impact than a shorter one by road. At the same time, though, globalizing trends in food systems are likely to continue, making localization harder and less likely to occur, despite the net economic benefits.

Acknowledgements

We are grateful to Katherine de Villiers for conducting some of the early analysis for this study and to the three anonymous referees for their very helpful comments on an earlier draft of the paper.

French Quality and Ecolabelling Schemes: Do They Also Benefit the Environment?

Genevieve Nguyen, Thomas L. Dobbs, Sherry K. Bertramsen and Bruno Legagneux

Introduction

Facing a major agricultural crisis, European countries are searching for alternatives to the intensive-production agricultural development model promoted since the early 1950s. Agenda 2000 introduced significant changes in the Common Agricultural Policy (CAP) by recognizing the multifunctionality of agriculture and by giving more importance to the 'second pillar', a term used to qualify all the measures to support rural development (Delorme, 2004; Ledent and Burny, 2002). Meanwhile, agrienvironmental schemes are taking on much greater importance in the overall policy mix for agriculture in European Union (EU) countries. Various schemes have been tried over the last 15 years, and new ones are being introduced in such countries as the UK (Dobbs and Pretty, 2004) and France (Miclet, 1998). The adoption of environmental schemes by French farmers has been somewhat successful, but farmers often have high opportunity costs and their decisions are driven primarily by economic considerations (Gafsi et al, 2002; Miclet, 1998). Policy makers now face substantial challenges to increase the adoption of environmental practices.

In France, there is a fairly long history of food 'quality' schemes. 'Quality' is used in the French context to denote taste, healthfulness and conditions of production. Two of the best-known French quality schemes are the Appellation d'Origine Contrôlée (AOC, controlled origin label) and the Label Rouge (LR, or Red Label) schemes, created respectively in 1919 and 1965 (Agreste, 2003). 'Eco-labelling' is a more recent phenomenon in both Europe and North America. Eco-labels are meant to provide consumers with information about a product's environmental impact. Often these labels contain information about the production process of the product,

Reprinted from Nguyen G, Dobbs T L, Bertramsen S K and Legagneux B. 2004. French quality and eco-labelling schemes: Do they also benefit the environment. *Int. J. Agric. Sust.* 2(3), 167–179.

as does organic labelling (Agriculture Biologique, in France). Both types of labelling schemes are gaining in importance for food products on both sides of the Atlantic. In comparison to environmental schemes, farmers in France tend to engage more easily in food quality schemes because of the price premiums consumers are often willing to pay for quality products. Although the standard guidelines of food quality schemes do not include any environment guarantees, consumers tend to associate quality food products with environmentally friendly farming practices, partly due to unclear market signals (Pujol and Dron, 1998).

As France, other EU countries, North America and other parts of the world place greater emphasis on schemes which reward farmers for environmental stewardship – both through the market and through government stewardship payments – it is important to know whether these 'quality' and 'ecolabelling' schemes do, indeed, provide measurable environmental benefits. If they do, policies can be implemented to foster and encourage these schemes, in which some portion of the incentive for farmer adoption comes through price premiums. Otherwise, a policy conclusion might be that though the schemes have possible health, taste or other consumer benefits, they should not be relied on for substantial environmental benefits. An alternative possible policy conclusion is that perhaps the criteria for eligibility and certification with these schemes should be broadened or strengthened to bring about greater environmental benefits.

In his theoretical analysis of the relationship between food quality and environmental quality, Thiébaut (1995) points out three possible levels where the relationship can be observed:

- at the *territorial level*, there can be joint production of final quality food products and environmental services (e.g. wine and landscape);
- at the *farmer's level*, there can be simultaneous production of quality food products and environmental goods (e.g. positive externalities or reduction of negative externalities);
- at the *consumer's level*, there can be joint demand for quality food and protection of the environment.

Kephaliacos and Robin (2003) suggest another way to look at the relationship between food quality and environmental quality. They suggest analyses at the *input level* (e.g. not allowing certain joint inputs) and at the *output level* (e.g. the nature of interdependencies between the quantities or characteristics of the outputs). Our study's main objective was to analyse the extent of the relationship between food quality and output quality at the farmer's level by looking at the production process and at the nature of the outputs.

Girardin and Sardet (2002) examine the potential environmental output effects of eight different sets of standards proposed for European farmers. By examining the nature of the input level standards (rather than using data from actual farms), they found 'organic agriculture' and 'integrated production' to have relatively high potential for producing positive environmental outputs. Although other standards examined had some positive aspects, they appeared not to have sufficient potential for improving environmental quality on arable lands (Girardin and Sardet, 2002).

Van Ravenswaay (1996) studies some of the challenges facing environmental labelling. She notes that environmental labelling has created two controversies. They involve (1) the potential for consumer deception, and (2) whether environmental labels should also serve environmental policy objectives. Consumers' ability to discern whether or not a product has been produced in an environmentally sound manner remains tenuous (Erickson and Kramer-LeBlanc, 1996). Lohr (1998) notes that there are many certifications – in addition to organic – for environmentally oriented production systems. She indicates that although consumer interest in purchasing food products with 'green' production characteristics is growing, given that existing ecolabels are not well-defined in consumers' minds, there is substantial potential for new labels with vague criteria that are not legally defined to generate confusion. Thiébaut (1995) articulates the additional problem of determining whether specially labelled products contribute to both 'internal' quality (e.g. taste) and 'external' quality (production of positive environmental externalities or reduction of negative ones).

For purposes of public policy analysis, it is useful to view labelled products from the standpoint of 'multifuntionality'. Agriculture is capable of producing food and fibre outputs, social outputs (e.g. rural employment opportunities and 'equitable' income) and environmental outputs. Many of the social and environmental outputs have 'public good' or 'externality' characteristics (Bougherara and Grolleau, 2002; Dobbs and Pretty, 2004). Policy issues associated with agricultural systems engaged in producing quality and ecolabelled products are twofold:

- Do the criteria established for particular labels, including labels originally developed for social reasons (such as territorial development), also effectively contribute to agriculture's environmental function?
- To the extent labelled products do provide positive environmental outputs, are those outputs types that consumers are willing (or might be induced) to provide compensation for in the market through price premiums? As environmental awareness and income levels rise in societies, a growing number of consumers may be willing to pay some price premium for environmental outputs that are essentially public goods or externalities. However, that willingness is likely to vary with the type of environmental output, and it is unlikely ever, by itself, to be adequate to induce socially optimal levels of environmental quality across the full range of environmental outputs potentially associated with a truly multifunctional agriculture.

Although farmers themselves have multiple goals – including stewardship and risk management goals – farm profitability is always one of the important goals that agrienvironmental policies must address. Therefore, policies will need to consist of a mix of schemes that both (1) facilitate enhanced market value for food and fibre products which result from farming systems that jointly produce environmental goods, and (2) provide non-market or extra-market incentives for a multifunctional agricultural system that enhances environmental quality.

The main objective of this chapter is to examine whether the production of quality food was associated with the production of any environmental benefits. The chosen study area is the Midi-Pyrenees region of south-west France, well-known for the diversity of farming systems and the importance given to the promotion of quality food schemes. Statistical analyses based upon data collected for a random sample of 107 farms are conducted to identify correlations between farms' environmental scores and their level of participation in major 'quality' and 'ecolabelling' schemes in use. These results are complemented by qualitative results drawn from in-depth case studies of five food quality schemes. Policy implications are presented in the last section of the paper.

Quality and Ecolabelling Schemes Examined[1]

One 'ecolabel' and three 'quality' categories were examined in this study. The ecolabel included in the study was Agriculture Biologique (AB), organic agriculture. France officially recognised organic agriculture in 1980, and allowed farmers to use the label 'product made from organic agriculture' and created public standards to regulate the industry (MAAPAR, 2001). Although we refer here to the French AB as an 'ecolabel', in reality, it has always been considered a regular food 'quality' label like others described below. Most French consumers think that the AB label guarantees not only the non-use of chemical inputs, but also the taste and health of the resulting food product (Loisiel and Couvreur, 2001; MAAPAR, 2004; Pujol and Dron, 1998).

The different quality label categories included in the study are:

(1) The *Official Sign of Quality (SOQ)*. SOQ products receive an official government label that requires producers to follow specific guidelines for production of the product. Included in this category are the Appellation d'Origine Contrôlée (AOC) and the Label Rouge (LR).[2] The French controlled origin label was established in 1919 for the wine sector. It then spread to milk products and, in 1990, to all other agricultural food products. The AOC label implies more than horizontal differentiation; it also testifies that the product has been produced from local raw products in a place-specific mode, and that its high quality characteristics are the result of substantial long-term collective and individual investments (Kilkenny and Daniel, 2001). The LR was created for products that possess specific characteristics and enjoy a superior level of quality that distinguish them from other similar products (MAAPAR, 2001). It guarantees a better taste and high standards of production, while the AOC guarantees primarily the origin of the product. The LR is a nationwide structure that ties highly

localized groups of producers and their supplier and processing networks together to deliver consumer products that differ from industrial products. The differences supposedly are distinguishable with regard to intrinsic quality, food safety, environmentally sound production practices and product image (Westgren, 1999).

(2) The *Other Cahier des Charges (CDC)*. These products are not under an official government label, but they are produced in a quality way under specific guidelines from a cooperative, supermarket or agricultural supplier. The CDC is the formal document that specifies the agreed production guidelines.
(3) The *Official Sign of Quality of Transformed Food (SOQT)* products. While SOQ products concern raw materials, the SOQT category pertains to the outputs of food industries, including cooperatives. It includes the LR and the AOC. The guidelines do not directly concern farmers; instead, they apply to processing or manufacturing of food. An example of this designation is AOC Roquefort. The quality label specifics the cheese's production process, rather than the process of producing the milk.
(4) The *In Process (IP)* category. Producers in this category were just starting to switch over to an ecolabel (AB) or quality (SOQ, CDC or SOQT) approach.

Data and Methods of Analysis

Data analysed in this study were collected by researchers from three different agencies – SOLAGRO (a private agricultural and environmental association), the Regional Chamber of Agriculture of the Midi-Pyrenees and the Department of Agriculture of the Haute-Garonne. The data were made available to a research team at the École Nationale Supériere Agronomique de Toulouse (ENSAT), in France. The original data set contained information on farmers' practices and factors that could be scored from an environmental standpoint. Farmers were called and asked if they were involved in any agrienvironmental schemes, ecolabelling programmes and quality labelling programmes. The usable data set covered 107 farm operations in the Midi-Pyrenees region of the south-west of France. The categorization of these farms is shown in Table 18.1. Fifty of those farms were participating in one of the eco- or quality-label programmes (including three that were IP). Farms being randomly sampled, the unequal distribution of the 50 farms across the different schemes corresponds to the distribution observed within the total population of farms in the Midi-Pyrenees region, where about three-quarters of the farms participate in the SOQ schemes (excluding AB).

Table 18.2 constitutes a glossary of environmental scores used in the analyses. This is not an exhaustive list of the environmental scores that were recorded for farms in the data set, but the list does include the scores most often used in our analyses. Environmental scores consisted of eight components. One set of aggregate scores (PS1 and PS2) was based on two broad components: (1) overall diversity of

Table 18.1 *Distribution of farms by quality code*

Quality code	*Quality approach*	*Number of farms*
AB	Organic agriculture (AB)	8
SOQ	Official sign of quality (AOC, LR, CCP)	25
CDC	Other cahiers des charges	9
SOQT	Official sign of quality of transformed food	5
IP	In process	3
N	Nothing	57
Total		107

production; and (2) appropriate use of inputs such as synthetic chemical fertilizer. A second set (PE1 through PE6) was based on a more detailed breakdown, consisting of six components: (1) water use; (2) soil fertility and erosion; (3) plant and animal diversity; (4) air quality (e.g. emissions of greenhouse gases); (5) resource consumption (e.g. net production of renewable energy); and (6) waste management. Analyses were carried out using various individual components and combinations of components.

The database includes other variables on the characteristics of the farms, including size and types of production. Farm size variables referred to in the Results section below are defined as follows: (1) SAU, score equal to one full-time employee on a farm; (2) UTH, number of hectares on the farm; and (3) MBS, an index of the economic size of a farm (a measure of the difference between the regional standard value of all production on a farm and the regional standard production costs).

Using the Statistical Package for the Social Sciences (SPSS), we carried out both factor analyses and analyses of variance to determine the correlation between a farmer's participation in any of the ecolabelling and quality labelling schemes and the environmental score of his or her farming system.

For purposes of statistical analyses, ecolabelling and quality approaches were ordered from presumed least environmental impact to presumed highest environmental impact, based on the level of environmental quality that each approach was thought to demand. Farmers not participating in any ecolabelling or quality approach were assigned a rank of 1 (one), IP farmers were given a 2 (two), those following an SOQT approach were given a 3 (three), those following a CDC approach were given a 4 (four), those following an SOQ approach were given a 5 (five) and AB farmers were given a 6 (six). This ranking was based on an inventory of environmental practices mentioned in the different quality schemes standard guidelines, discussions with agricultural technicians and experts, and conclusions drawn from diverse field studies (Bourdais, 2001; Pujol and Dron, 1998).

In order to complement the above quantitative results and to get more insight on the nature of the relationship between quality practices and environmental practices, in-depth interviews were conducted with 85 randomly sampled farmers

Table 18.2 *Breakdown of environmental scores used in the SOLAGRO's environmental diagnosis tool DIALECT*

PART 1 – A global approach of the farming system with two scores adding up to 100
PS1: This score, worth 70 points in total, defines the mix of the farm and the diversity of production. It includes plant diversity (30 points), animal diversity (22 points) and natural elements and space (18 points).
PS2: This score, worth 30 points, defines the rational use of inputs on the farm. It includes the use of nitrogen (7.5 points), phosphorus (3.0 points), water (6.0 points), phytosanitaries (7.5 points) and energy (6.0 points).
PART 2 – A thematic analysis of the impact of agricultural practices on different elements of the environment (water, soil, biodiversity, air, energy and inputs, waste)
PE1: This score, worth 100 points, describes the quality and quantity of water used on the farm. It includes nitrogen discharges (14 points), phosphorus discharges (14 points), management of water (14 points), phytosanitary residue (15 points), effluent discharges (14 points), protection by organization of farm space (15 points) and protection by natural elements (14 points).
PE2: This score, worth 100 points, describes soil fertility and erosion. It includes management of organic material (35 points), risk of erosion (45 points) and quality of soil and pollutants in the soil (20 points).
PE3: This score, worth 100 points, describes plant and animal diversity on the farm or ranch. It includes natural elements (25 points), permanent prairies that are not fertilized very much (20 points), spaces with weak potential, such as dry or wet areas (10 points), zones of biological interest (15 points), absence or limited use of pesticides (20 points), threatened animal breeds (5 points) and old varieties of plants (5 points).
PE4: This score, worth 100 points, describes the quality of air on the farm or ranch. It includes emissions of greenhouse gases (35 points), emissions of ozone-depleting and acetic gases (15 points), emissions of phytosanitaries (25 points), odour nuisances (10 points) and production of oxygen (15 points).
PE5: This score, worth 100 points, describes the consumption of resources on the farm or ranch. It includes direct energy consumption (20 points), indirect energy consumption (15 points), phosphates purchased (15 points), potassium bought (15 points), water consumed (15 points) and net production of renewable energy (20 points).
PE6: This score, worth 100 points, describes the storing and handling of waste on the farm or ranch. It includes the handling and storing of dangerous wastes (50 points), the handling and storing of potentially dangerous wastes (20 points) and the handling and storing of plastic and metal wastes (30 points).

participating in five quality programmes: (1) CCP[3] 'Covapi' (apples); (2) AOC 'Chasselas' (raisins); (3) CCP-1GP 'Melon du Quercy' (melons); (4) LR 'Poulet Roux du Gers' (chickens); and (5) LR 'Veau de l'Aveyron et du Ségala' (calves) (Allhoff, 2002; Carton et al, 2002; Teynier, 2002). These farmers, all located in the Midi-Pyrenees region, were questioned about the characteristics of their farm, their motivations to engage in a quality scheme, their quality and environmental practices, and their perception of environmental problems. Information on the farmers' quality organizations and guidelines also were collected in order to analyse the extent to which recommendations on environmental practices were included in the organization's rules and guidelines.

Results of Statistical Analyses[4]

Farm size and adoption of environmental practices

A factor analysis was conducted to identify groups of farmers that share similar characteristics – such as high environmental grades, size of farm, income, ecolabel or quality approach followed, or number of workers – and to determine if either large or small farms tend to be associated with high total environmental scores or if either large or small farms are especially likely to be involved in quality or ecolabelling schemes. Four distinct clusters were identified in this analysis (Figure 18.1). One cluster (cluster A) was composed of farmers with relatively small farms, low

	Total variance explained by each component	
	F1 40%	F2 30%
	Component Matrix	
Quality code	.057	.841
SAU	.740	–.268
UTH	.789	.352
MBS	.884	.036
PS1 + PS2	–.209	.763

Extraction Method: Principal Component Analysis

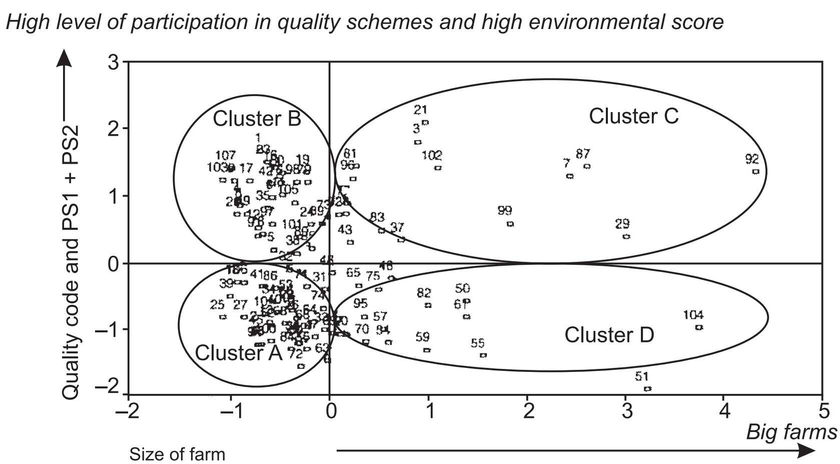

Figure 18.1 *Factor analysis of quality codes, SAU, UTH, MBS and PS1 + PS2*

environmental scores (PS1 + PS2) and a low level of participation in quality and ecolabelling schemes (i.e. not participating at all, IP, or participating in a scheme thought, a priori, to provide less environmental benefit than some others). Another cluster (cluster B) also was composed of relatively small farms, but these farms had high total environmental scores and participated in schemes thought, a priori, to provide greater environmental benefits (e.g. AB). Larger farms were split in a similar fashion, with about half (cluster C) engaged in higher-level quality or ecolabelling schemes and having high environmental scores, and the other half (cluster D) having low total environmental scores and participating in no or lower-level quality and ecolabelling schemes. The importance of environmental practices does not appear to be correlated with the size of the farm. However, on average, large and small farms participating in a quality scheme have significantly higher environmental scores than the non-participating farms.

Farm production specialization, type of quality or ecolabel and adoption of environmental practices

Analysis of variance (ANOVA) tests were then run to determine if particular quality and ecolabelling schemes were associated with the various environmental indicators:

(1) Comparison of quality and ecolabelling schemes on the basis of mean aggregate environmental scores using the first set components 'PS1 and PS2' reflecting a global approach of the farming system.

Farmers participating in SOQT schemes had the highest mean score and farmers involved in AB and SOQ programmes were next highest, but substantially below the mean for SOQT farmers (Figure 18.2). This high mean environmental score for farmers in SOQT could be explained by the fact that the majority of them raise sheep and produce milk for the labelled cheese products, based upon extensive farming systems with a minimum of negative environmental impact. The types of farming systems they use have direct effects on environmental scores independent of farmers' adoption of particular environmental practices. Farmers not involved in any ecolabel or quality programmes, as expected, had the lowest average aggregate environmental scores, but that score was only slightly lower than the average for farmers in CDC schemes. The mean environmental score for SOQT farmers was significantly higher (at the 5 per cent level) than the mean scores for farmers in all other categories – including farmers not participating in any quality or ecolabelling programmes (symbolized by N) – except for farmers in the AB and IP categories.

(2) Comparison of quality and ecolabelling categories with respect to mean environmental scores based on the sums of individual thematic components PE1 through PE6.

	Sum of squares	df	Mean squares	F	Sig.
Between groups	8377.616	5	1675.523	6.766	.000
Within groups	25011.52	101	247.639		
Total	33389.13	106			

Figure 18.2 *ANOVA for quality codes and PS1 + PS2*

N farmers again had the lowest mean score, but in this case AB farmers had the highest score. This is what was originally expected. SOQT farmers, as in the first test, performed relatively well environmentally, better than IP and SOQ farmers. Once again, CDC farmers did not perform as well as farmers in other quality and ecolabelling programmes. Multiple comparisons of the mean scores show that AB farmers performed significantly[5] better than farmers in all other categories except for those in the SOQT and IP categories.

(3) Three additional ANOVA analyses conducted in which quality and ecolabel categories containing a limited number of observations were combined. The N, AB and SOQ categories remained separate, but the SOQT, CDC and IP categories were combined into a new category labelled O, for others.

- A first ANOVA was conducted with this grouping to examine the relationship between quality/ecolabel categories and farm size, as measured by the MBS variable. Results indicate that the AB farms are smallest in terms of this economic 'value added' measure, and SOQ farms are the largest. Farmers not involved in any quality or ecolabelling programme are the second largest, on average, by this measure. The mean differences between SOQ farms and farms in all other categories are significant, but the differences between farms in the other categories are not significant. The relatively high value for economic output on SOQ farms was not unexpected, because products with SOQ labels, including those with the LR, often generate substantial price premiums. Westgren (1999) indicated that LR products can command prices up to 300 per cent over conventional prices. It was somewhat surprising that AB farmers had the lowest mean MBS value. However, the MBS index is more an indicator of farm size than of the real level of farm income. Organic farmers in the study had fewer hectares under production, on average, than did SOQ farmers.

- A second ANOVA, with the same quality category grouping, was conducted to isolate effects on soil fertility and erosion, as measured by PE2. AB, SOQ and O farms had significantly better PE2 performance, on average, than did farms not participating in any of these programmes.
- Farms participating in quality and ecolabelling programmes also performed significantly better, on average, on the environmental indicator for plant and animal diversity (PE3) than did non-participating farms. AB farms performed best, but not significantly better than SOQ and O farms.

Results of Qualitative Analyses

A sample of 85 farmers participating in five selected quality schemes were questioned about their motivations for adopting environmental practices. The analysis of their answers suggested that the relationship between food quality and the environment appears mainly through inclusion in the SOQ guidelines of environmental practices. These have an impact on the quality and the image of the product and that can send a clear signal to consumers. The environmental practices include reduction in the use of chemical inputs, preservation of natural habitats in fields, preservation of the land's natural characteristics, and respect for animal well-being. The guidelines of the CCP 'Covapi', LR 'Poulet Roux du Gers', and 'Veau de l'Aveyron et du Ségala' do, indeed, include explicit recommendations on environmental preservation and animal well-being. In contrast, the AOC 'Chasselas' and CCP-IGP 'Melon du Querey' guidelines were based on pre-existing farming practices (Table 18.3). For example, the list of chemicals a farmer can use is no stricter than the European norms. The quality approach only requires these fruit producers to reduce the number and the period of the treatments. Farmers participate in quality schemes for economic reasons first.

Table 18.4 gives some indication of the price premiums farmers can get from quality products. Farmers do receive a higher price for quality products, but the price difference is not always sufficient to cover costs associated with the labelling process. Only farmers producing top quality AOC 'Chasselas' and having a 100 per cent

Table 18.3 *Selected qualitative results of the study of five SOQ schemes*

	LR 'Poulet Roux du Gers' (poultry)	*LR 'Veau de l'Aveyron et du Ségala' (calves)*	*CCP 'Covapi' (apples)*	*AOC 'Chasselas' (raisins)*	*CCP-IGP 'Melon du Quercy' (melons)*
Type of participation in the quality scheme	Through the cooperative	Through the cooperative	Individual	Individual	Individual
Motivations of farmers to participate in the scheme	Economic (value-added + better conditions of work)	Economic (value-added, reduction of market risks and price variations)	Economic (value-added)	Economic (value-added, market niches, luxury products)	Economic (value-added)
Environmental practices specified in guidelines	Animal well-being: building norms, number of animals per unit of surface, planting of plants to provide shade	Animal well-being: building norms, number of animals per unit of surface	Reducion of chemicals Preservation of biodiversity Preservation of the soil's characteristics	None	None
Any additional environmental practices adopted independently of the guidelines		Improvement of the farm's surrounding: management of waste, preservation of the natural environment	Reduction of the traditional practice of cutting trees to accelerate fruit maturation		
Sensitivity of farmer to environmental issues	No	Yes, important to improve the image of agriculture and attract tourists	Yes, important to improve the image of the product for consumers and to improve the quality of life	Yes, but independently of the quality approach	Yes, but independently of the quality approach
Additional factors contributing to the adoption of environmental practices		Dynamism of the farmer SOQ organization (collective action)	Role of the SOQ organization's technicians

price premium consider the quality approach profitable. Nevertheless, the schemes allow farmers to occupy specific market niches and they do, indeed, help assure a minimum income. This was particularly true for farmers producing the LR 'Veau de l'Aveyron et du Ségala' during the BSE crisis. Farmers' sensitivity to environmental concerns may grow, however, as a result of having to follow the environmental guidelines embedded in the schemes.

The extent of changes in farming systems and practices induced by quality guidelines varies with the scheme. The respect for animal well-being required of poultry producers under the LR 'Poulet Roux du Gers' or the LR 'Veau de l'Aveyron et du Ségala' label mainly involves certain building specifications and small changes in breeding practices. In contrast, changes in fruit production practices could be significant in the case of the CCP 'Covapi' label, because farmers have to adopt new chemical and other production practices. In this case, farmers tend to become more sensitive to environmental issues and naturally develop new environmental practices independently of the label guidelines. Technicians for the quality organizations play an important role in developing farmer sensitivity to environmental issues.

The analysis revealed two other major determinants of the adoption of environmental practices by farmers: the impact of these practices on the farm's productivity and the opportunities for their monetary reward. We observed that certain environmental practices have been adopted because they help reduce yield risks or lower operating costs. Farmer behaviour towards the environment is also very dependent on consumer attitudes. It is easier for farmers participating in the CCP 'Covapi' to stop using chemicals because they can be compensated by a price premium consumers sensitive to healthy products are willing to pay. Similarly, to improve their image to consumers and make their territory more attractive for tourism, farmers participating in the LR 'Veau d'Aveyron et du Ségala' have decided, in addition to satisfying the SOQ guidelines, to preserve the natural environment surrounding their farms. Farmers selling products directly to consumers – like 'Covapi' fruit producers or producers of 'Veau d'Aveyron et du Ségala' meat – will, indeed, be more sensitive to environmental concerns due to their close contact with consumers. The difficulty in commanding price premiums for environmental practices less visible to consumers in quality schemes makes those practices less attractive to farmers.

Policy Implications

This research showed that organic farms and farms enrolled in various quality labelling programmes in France do provide some environmental benefits to society. However, they do not necessarily perform better than other farms on all environmental measures. This is not surprising for French food quality labels, as most of those labels were not originally designed for environmental purposes. Originally, most were intended to enhance marketability through appeals to such consumer values as taste and health. Conversely to consumer common opinion, the production of quality food is not necessarily associated with the production of environmental benefits. Yet, the policy question remains how to bring farmers to adopt environmental practices using market mechanisms and, in particular, consumer willingness to pay for a price premium to get higher global quality products.

There do appear to be opportunities to strengthen certification criteria to enhance environmental quality provided by the various French labelling schemes by explicitly including some environmental requirements in the food quality production standard guidelines. However, building environmental objectives into the certification criteria for products carrying regional and quality labels does not assure that the added social value will be reflected in higher market prices, due to the public goods and externality problem discussed in the introduction to this article. Bougherara and Grolleau (2002) suggest ways to enhance possibilities for at least some of this added value to be reflected in prices farmers receive. Third-party involvement in establishing and verifying environmental criteria is one important step in establishing credibility with consumers. Most private labels in our study (those in the CDC group) do not have such third-party involvement and, as indicated in our study results, farms with products carrying those labels tended to have lower overall environmental performance than did farms producing products with government sanctioned labels.

There have been a few efforts by farmer organizations in France to develop specific 'ecolabels'. These are commercial labels, not SOQ labels. They are, for the moment, too new to provide specific lessons. However, ecolabels may not constitute an efficient signal to consumers about farmers' environmental stewardship, due to an asymmetric information problem associated with the great increase in the number of all sorts of official and non-official quality labels. It is difficult for consumers to access and understand all the guidelines and to sort out the highly heterogeneous guidelines regarding prescribed environmental measures and their likely efficacies. As the EU continues with reforms in its CAP, a critical issue is what mix of government direct payments and market mechanisms to use in fostering expanded use of environmental practices. The resolution of that issue depends greatly on the extent to which quality and ecolabels can send clear and reasonably reliable market signals to consumers who are willing to pay for environmental goods provided jointly with food products.

Due to the problem of information overload, an ecolabel's success in the marketplace also depends on its ability to capture consumers' attention (Bougherara and Grolleau, 2002). This suggests that if quality label schemes are to have more emphasis on environmental criteria than in the past, market value may be enhanced by emphasizing, in labels and advertising, those environmental benefits that are verifiable and in which consumers are most interested. For example, our results showed that farms participating in quality and ecolabelling schemes performed better with respect to plant and animal diversity than did non-participating farms. Biological diversity has growing public appeal, because of desirable landscape implications and a multitude of other environmental benefits, and consumers may be willing to pay some modest price premiums for food products they are convinced result from farming systems that add to biodiversity.

Ecolabelling based on regionally identified quality products represents a potentially attractive market incentive approach to help improve farmers' environmental stewardship. Nevertheless, the future of this approach depends on CAP reforms and discussions within the World Trade Organization (WTO) on the Trade-related Aspects of Intellectual Property Rights (TRIPS) agreement. There is no clear indication whether the EU is working towards a global policy of product quality and origin, which is needed in order to improve the credibility of consumer information. Such a policy would be costly to implement, as it requires a general consensus and the integration of highly interdependent factors – for example, the technical definition of a product, the definition of its typicity and consumer knowledge of these definitions (Barjolle and Sylvander, 2000). Moreover, political conditions for the emergence of such a policy are not yet in place, due to important pressure on the WTO coming from the 'new' world, lead by countries like Australia and the US, and from Latin America, There is a clear distinction between the 'old' and the 'new' world's views regarding quality product labelling. While the 'old' world is defending the recognition of the commercial value of labels, which seek to link products of quality to their geographical origin, the 'new' world tends to condemn such labels as simply another trade barrier.

Although ecolabelled food products can command price premiums, as evidenced especially by organic crop and animal products in many countries, it will be difficult to create and sustain substantial price premiums based on environmental benefits for products mass marketed (Giraud, 2002). Since a large portion of food purchases are made in supermarkets, market signals alone are unlikely to be sufficient to induce socially efficient levels of environmental quality on the agricultural land masses of European and north American countries. Stewardship payments to farmers under national agrienvironmental programmes, together with increased regulatory powers, also will be necessary to achieve some of the multifunctionality expectations now being placed on agriculture in industrialized countries.

Notes

1 See Bertramsen et al (2002) for a brief comparison of 'quality' and 'ecolabelling' schemes in France and the US.
2 The AB belongs to the SOQ category.
3 The CCP correspond to a specific quality CDC, but it can be considered as a certified label only if it is associated with the European 'Indication Geographique Protegee' (IGP) label. This latter certifies an origin quality. Therefore, we classify the CCP among what we call the CDC labels.
4 For more complete and detailed results of the empirical analyses, see Bertramsen (2002).

The Growth of Urban Agriculture

Nelso Companioni, Yanet Ojeda Hernández, Egidio Páez and Catherine Murphy

In recent years a strong urban agriculture movement has developed in Cuban cities and suburbs.[1] The goal of this movement is to maximize the production of diverse, fresh and safe crops from every patch of previously unused urban land. This urban production is based on three principles: organic methods, which do not contaminate the environment; the rational use of local resources; and the direct marketing of produce to consumers. Thus our urban agriculture fits the concept of sustainability, which in this context means the abundant use of organic matter and biological pest controls, and adherence to the principle of local inputs. The local sale of produce has played a significant role in meeting local food requirements (Companioni et al, 1997).

Urban agriculture has characteristics that differentiate it from conventional agriculture and large-scale production systems, such as the diversity of production and the many people who participate. This gives a special aspect to extension work, where new management models and work styles must be developed to achieve sustainable production levels in each neighbourhood and region.

Urban agriculture is participatory, not only in the sense of the broad base of involvement, but also in demanding diverse responses to the heterogeneity of local conditions, requiring a variety of techniques to create the best possible conditions for production. Because of its geographical location and intended market, this movement must be low-input, use no toxic pesticides, make efficient use of water, and carefully manage soil fertility and the cultivation of its crops and animals. Urban agriculture has received and receives special attention from the highest levels of the Ministry of Agriculture and other government officials.

Reprinted from The growth of urban agriculture by Companioni N, Hernández Y O, Páez E and Murphy C. 2002. In *Sustainable Agriculture and Resistance*, Funes F, García L, Bourque M, Pérez N and Rosset P (eds), 2002. Food First Books, 398 60th Street, Oakland, CA 94618, USA.

Urban Agriculture Yesterday and Today

During the first half of the century, urban agriculture existed on a small scale, involving a few people, and was aimed at the production of a few plant species (mainly leafy vegetables), the rearing of domestic animals in backyards and provisioning of foods for families.

Beginning in the 1960s, high-tech horticultural production techniques were introduced, based on complex technology and crop management systems with a heavy use of chemical products, as are found in hydroponics and 'zeoponics' (production in zeolite susbtrate). The high degree of specialization in these production systems and the development of large enterprises for producing vegetables and other crops during the 1970s and 1980s monopolized the vegetable market, relegating small-scale producers to a second tier (Companioni et al, 1996a).

Like many other countries, Cuba after the Revolution opted to be in the vanguard of the 'Green Revolution', which involved the industrialization of agriculture and the adoption of practices aimed at producing sufficient food for the country. After the Earth Summit in Río, Cuba moved with the world community towards a new emphasis on a more natural agricultural system, through which food quality, the nutrition of the population and natural resources would benefit. Urban agriculture re-emerged recently in this new context for several reasons: the economic difficulties of the 1990s; the low quality of vegetables on the market; shortages of traditional spices and seasonings; and the under-exploited production potential of cities. With a renewed emphasis on urban farming, relatively high levels of production in small areas were made possible by paying close attention to existing local resources and the potential for selling goods locally.

The simplicity of this form of production, and the increase in yields while still improving the technology, allowed for the rapid development of the popular movement in urban agriculture. This new sector has created 160,000 jobs, taken by people of various occupations and backgrounds, including workers, masons, mechanics, housewives, retired people and professionals (López, 2000).

Employing a large number of people in urban agriculture is one of the greatest social impacts of this movement. Driving these changes was the potential for increased income generated by selling produce from urban gardens; (Figure 19.1) this attracted the attention not only of workers, but also professionals from diverse backgrounds, who received state supports in the form of land, credit, services and/or inputs. This new agricultural labour force has brought dynamism and innovation to every municipality.

In each territorial unit, services for urban agriculture are grouped together in what we call a Municipal Urban Farm Enterprise. This administrative unit helps coordinate all urban agricultural activities in the municipality in a variety of ways. It is the source for extension and technical assistance, helps link urban farmers and gardeners with each other, and builds links with research, educational and service centres (Ojeda, 1999). Each Municipal Urban Farm also has the responsibility of organizing production and determining the appropriateness of different technologies for each of

Figure 19.1 *Urban agriculture: public sales outlet, Havana*

its subunits, taking into account local resources, inputs and the potential of the land. Intense technical training for producers has played a decisive role in the achievements attained so far.

Premises of Urban Agriculture

Several basic premises explain the strong potential of urban agriculture:

- Urban centres have the highest demand for those foodstuffs which are easily perishable when transported. Thus there is a basic logic to the notion that perishable foods should be produced as near as possible to the consumer.
- Vegetables, fruits, flowers, spices and intensive animal production all require a large labour force, which is available in towns and cities. In Cuba, 75 per cent of the population is urban, most of which came originally from rural areas; thus, many urban dwellers have empirical knowledge about crop management and livestock production.
- The growth and spread of cities invariably creates many empty spaces in peripherial areas, which often become trash-dumps that are sources of disease vectors, are a danger to human health and despoil the urban environment. Using such areas for food production has eliminated these dangers and has made Cuba's cities healthier and more beautiful.

Basic Principles

Planning for urban agriculture in Cuba is guided by a set of basic principles defining its objectives and organization. Among them are the following:

- uniform distribution throughout the country;
- logical correspondence between production and the number of dwellers of each region;
- crop–animal integration with maximum use of synergies to boost the production of each;
- intensive use of organic matter to boost and preserve soil fertility, and biological pest controls;
- use of each patch of available land to produce food, guaranteeing intensive production and high yields of crops and animals;
- multidisciplinary integration and the intense application of science and technology;
- a fresh supply of good quality products, offered directly to the population, guaranteeing a balanced production of not less than 300g of vegetables daily per capita and an adequate variety of animal protein sources;
- maximum use of the potential to produce food, such as the labour force available and the recycling of wastes and by-products for plant and animal nutrition.

Organizational Structure of Urban Agriculture in Cuba

In Cuba today there is an urban agriculture structure in all cities and towns, thanks to the impact and rapid development of this popular form of food production and to the degree of urbanization of the Cuban population (see Table 19.1).

The National Urban Agriculture Group – composed of specialists and government officials from different scientific and government institutions, and urban farmers – regulates and directs this effort, exercising its influence at different levels all to way to the grassroots through provincial and municipal groups. Regional and local groups are responsible for the organization, development and regulation of urban agriculture in their zone, and the coordination between all entities and persons related to production, processing and distribution of food within the boundaries of each territory and province.

Within each Popular Council (local government at the neighbourhood level), a representative or agricultural delegate coordinates urban agriculture. Likewise, many activities related to urban agriculture – such as veterinary medicine, plant protection and biopesticide production – are represented at the Popular Council. Different areas of responsibility are coordinated through the Popular Councils, which take into consideration the unique characteristics of local systems of production and

Table 19.1 *Urbanization in Cuban province*

Santiago de Cuba	70.2
Guantánamo	59.6

oversee technical and service units such as the veterinary clinic, farmers' shop, nurseries, laboratories for the production of biological products and others.

Within a municipality, the coordinating activities of the Popular Councils are carried out through the Municipal Urban Farm, which in addition to its coordinating role, has the infrastructure necessary to carry out technical and service activities, with the capability to gather together scientific and technical resources and farmers from different productive areas and related institutions within its territory.

Twenty-six administrative sub-programmes attend to urban agriculture. These are tied to specific topics such as vegetable production, medicinal plants, herbs, grains, fruits and rearing of animals (hens, rabbits, sheep, goats, pigs, bees and fish), all of which can be found throughout the country (Table 19.2).

Vegetables and fresh herbs (organoponics, intensive vegetable gardens, small plots and backyards)

This was the first urban agriculture activity carried out and hence is the most developed. The goal for this type of urban agriculture has been set at producing 30 million quintals[2] (1,380,000 metric tonnes) of fresh vegetables per year, with yields above 20kg/m^2 per year in organoponics (raised beds filled with organic matter), 10kg/m^2 per year in intensive vegetable gardens and 10kg/m^2 per year in small plots and backyards. The goal for the end of 2000 was to have at least 5m^2 per inhabitant dedicated to these types of production, making a substantial contribution to the national goal for all vegetable production of 300g of fresh vegetables daily per capita.

Source: GNAU, 2000

The heterogeneity of Cuba and the diversity of possible ways to grow vegetables have combined to generate distinct production systems. The most common are the following:

Organoponics and intensive vegetable gardening

These have been the most important methods over the past years and have gone a long way toward helping us rediscover our horticultural traditions. These systems are an example of how scientists and gardeners can work together to develop new production methods (MINAG, 2000). The main difference between these two systems of production lies in the fact that organoponics are generally located in areas with infertile soils or with production constraints. For example, organoponics can be built on artificial surfaces, on which containers are placed and filled with a mixture of organic matter substrate and soil, in which to grow the crops. The intensive vegetable garden is developed on parcels of relatively good soil, without using raised beds, though organic matter is applied directly during preparation for planting (Peña, 1995, 1998). (Figure 19.2.)

Small plots, patios and popular gardens

In this popular form of production, as a rule, the area cultivated is very small and is determined by how much useful or arable space exists between buildings, between houses and streets, or in a patio or a state-owned urban space that can be converted to gardens. In general, the small plots, patios and popular gardens situated in suburban areas are larger than those in the city centres. This type of production now makes significant contributions to household and regional food

Figure 19.2 *Organoponic intensive farming at the 'Gilberto León' Cooperative*

supplies. At this point there are 104,087 parcels and patios under production, covering an area of 3595 hectares, which produce more than organoponics and intensive gardens combined. This type of land use has several positive effects. The small plots, patios and popular gardens have made it possible to feed the urban population; have promoted the development of an urban culture favourable to agriculture; have eliminated the abandoned spaces which in the past may have been breeding grounds for disease vectors and rodents; and have provided socially useful and productive employment opportunities (Ojeda, 1997).

Self-provisioning at factories, offices and businesses

The concentration of industrial production and of innumerable educational, health and service facilities in the main population centres demands the operation of hundreds of workers' cafeterias, whose food supply requires large quantities of diverse agricultural products. A considerable number of workplaces have organized agricultural production in areas bordering, or close to, their facilities. This helps to meet the cafeterias' demand for food without reducing the food resources available to others in the neighbourhood. The magnitude of this form of production has reached a level such that it must be considered a separate form of urban agriculture, particularly because of the differences between these self-provisioning farms and others. In the country's capital alone, there are more than 300 such farms in production. They total an area of 5368 hectares, on which large quantities of vegetables, root crops, grains and fruits, as well as meat, milk, fish, eggs and herbs are produced.

Suburban farms

On the edge or outer ring of Cuban cities we find many integrated suburban farms. They grow from the urbanism movement, are considered part of the urban environment and are a key feature in planning for urban growth and development. Although they could never meet all the food needs of the urban population, they are larger than, and have a higher degree of integration among their sub-components than do the small plots and intensive gardens in the interior of the cities. Typically they cover between 2 and 15 hectares. The type of production found on a suburban farm will be strongly influenced by the surrounding population. We can see this from the point of view of infrastructure, recycling of waste products, the crops grown and animals raised, how the products are marketed, etc. This form of agricultural production is characterized by intensive cultivation, efficiency of water use and the maximum reduction of agrotoxins. Suburban farms have reached an important level in the past few years, particularly in the cities of Havana, Santa Clara, Sancti Spíritus, Camagüey and Santiago de Cuba. In the city of Havana, 2000 small private farms and 285 state farms are under production; together these cover an area of 7718 hectares and are highly productive.

Shaded cultivation and apartment-style production

These systems are in their initial phases of development. Covered or shaded production utilizes mesh tents or 'shade houses' of Spanish, Israeli or Cuban design for growing crops and germinating seedlings. Work is underway to develop a complete technology appropriate for Cuban conditions, allowing for the year-round cultivation of horticultural crops, especially during the hottest months when the sun is at its most intense. Apartment-style agriculture is very diverse. It includes a range of practices, including cultivation with diverse soil substrates and nutrient solutions, mini-planting beds, small containers, balconies, roofs, etc., with minimal use of soil. This type of production has its own unique technologies and forms of organization (Carrión, 1996).

Results of the vegetable sub-programme

In recent years this programme has experienced sustainable growth, both in production levels and in the yields obtained (see Figure 19.3). During 1999 vegetable production in organoponics and intensive gardens provided the population with 215g/day per person of fresh horticultural crops (MINAG, 1999), which represents a little more than half of the goals set (see Table 19.3). The most success has been achieved in Cienfuegos, Ciego de Ávila, Sancti Spíritus and Havana. This programme has been the laboratory for testing, confirming and consolidating the principles, objectives and overall perspectives for urban agriculture in Cuba.

Small-scale 'popular' rice production

This sub-programme has made significant advances in the past three years. Small-scale rice production is growing in all of the country's provinces, and the use of local resources in crop management has generated rice yields above 5tons/ha in many units, a higher level than that which is achieved on state farms.

Medicinal plants and dried herbs

Like the previous programme, this is a recent one within urban agriculture. Herbs and medicinal plants are grown in organoponics and intensive vegetable gardens; yet they have their own programme, which means their production is taken into account in regional planning according to local needs. In some cases, a portion of the production is sold via the Ministry of Public Health for processing into 'green' medicines, which are distributed through the network of public pharmacies. The rest is sold fresh or dry for domestic consumption. Dried herbs are destined for Cuban kitchens; high levels of production make drying essential. Consumption of dried seasonings in Cuba has reached an annual per capita level of 120g. An intensive educational and promotional campaign has been carried out to promote knowledge of their preservation, processing and home use, through publications and radio and TV programmes (Figueroa and Lama, 1997, 1998, 1999).

Ornamental plants and flowers

This is the least advanced sub-programme in the majority of the provinces. There are only a few units dedicated specifically to flower production. This programme has grown in areas around Havana and also others such as Camagüey and Ciego de Ávila. The initial goal is to produce five dozen flowers per capita per year. (Figure 19.4.)

Fruit trees

Despite being a recent addition to the urban agriculture movement, the planting, care and uses of a variety of fruit trees along urban perimeters has long been a tradition in Cuba. This sub-programme has demonstrated a high productive potential, especially in mangoes, avocados and citrus. Current plans contemplate a broad programme of nurseries and grafting in future years in order to accelerate urban fruit production.

Poultry

This sub-programme, specializing in hens and ducks, is the most advanced of the animal production programmes in urban agriculture. Producers are assigned ten females and one male of the semi-rustic local chicken breed. This breed has been

Figure 19.4 *Ornamental plant nursery at the Alamar UBPC in Havana*

produced by crossing a locally adapted Creole hen with a more productive line of hen, such as a Rhode Island Red. From this cross, birds were obtained that are characterized by their resistance to environmental adversity and high productivity of meat and eggs. During their adult stages, this hen, with good feeding (109g/bird/day), will lay eggs year-round with an average annual production of 200 eggs/bird.

A certain amount of progress has been reached with rearing ducks, as it is the domesticated bird with the fastest growth rate. In just seven to eight weeks, ducks can reach between 2.8 and 3.2kg (live weight), converting close to 3kg of feed for each kg of weight gained. Ducks are also less sensitive to environmental stress and food quality, and more resistant to some infectious diseases that are common in birds. In addition to chickens and ducks, geese, turkeys and guinea hens are also produced on a small scale (Companioni et al, 1996b).

Swine

This sub-programme has special features because rearing pigs within city boundaries requires strict sanitary control measures and vaccination. This programme is focused in suburban areas, under the following requirements defined by the Institute of Veterinary Medicine (IMV):

- adequate food supply;
- sufficient water supply for drinking and hygiene;
- confinement;

- a residue pit or biogas digester;
- a cement or tile floor and a roof for protection from weather.

To begin rearing pigs, the prospective producer must sign agreements with the swine production group and the Territorial Technical Service for Swine Production. Through these agreements the producer purchases 12–20kg piglets at a reduced price, as well as part of the necessary feed for fattening. After four to five months, when the pig reaches 90kg or more, the contracted quantity of meat agreed upon by the producer is purchased by the state at the official price and the surplus is sold at higher prices.

If the new pig farmer can produce or find his own pig feed, he need only buy a vitamin and mineral supplement for his animals. To fatten 40 animals on a 140-day cycle, and to finish 100 animals in a year at an average weight of 90kg, it would be necessary to plant four hectares of soybeans, seven hectares of sunflowers and six hectares of sugarcane.

Organic matter

Among the working guidelines for urban agriculture is 'to systematically apply organic matter by using all available local alternatives, and to systematically develop local programs to assure adequate supplies of organic matter'. In view of the importance of this activity, and to realize its potential, a sub-programme was created in charge of organization, promotion and development of organic matter sources, and to assure their collection, processing, conservation and distribution (GNAU, 2000). The National Urban Agriculture Group (GNAU) coordinates these activities, supported by the Organic Fertilizers Reference Center, located at the National Institute for Fundamental Research on Tropical Agriculture (INIFAT) in the City of Havana, as well as by provincial and municipal organic fertilizer centres. This structure extends to the grassroots with centres organized by each Popular Council which receive technical assistance from a Technical Operations Group made up of specialists and farmers from different organizations and institutions. Territorial Organic Fertilizers Centers are responsible for organizing and advising the activities in their territory, geared toward the largest possible proliferation of small production units located at the sources of organic matter or at agricultural production units, to get this important input directly to the farmer or gardener. This activity is characterized by a great use of animal manures and sugarcane filter cake mud (*cachaza*), while the processing of urban agricultural wastes to turn them into organic fertilizers is still insufficient.

Seeds

This sub-programme is aimed at regional self-sufficiency of seed production and distribution, which is critical to the success of urban agriculture and without which production would not be stable or sustainable, because it is essential to have the right seed at the appropriate time for sowing. A network of provincial seed farms has been created, whose job it is to keep the supply of seeds flowing. For seeds that are easily produced by farmers and gardeners, such as cucumber and cowpea, the goal of this programme is to make production units self-sufficient for such crops. This has now been achieved in all urban farms.

Animal feed

The jump in small-scale animal rearing cannot be maintained by solely recycling agricultural waste products as feed. To maximize production of animal protein per unit area, a programme was created to supplement the use of all household scraps and crop residues with the production of feeds on urban farms. Typically these feeds consist of grains, tubers, roots and sugarcane. Despite some progress, most units are still not self-sufficient in terms of animal feed.

Science, technology and training

Training of urban farmers is critical to perfecting the production technologies being employed. In the training sub-programme we focus on practical training, which takes place right in the garden plot, raised beds or animal rearing pens. We have built an extension system, which counts on the participation of its own extension agents, plus research centres, the most experienced farmers and gardeners, and other individuals and institutions related to urban agriculture. Extension is at all times tailored to local conditions and needs, providing farmers with the latest theoretical and practical information.

Other sub-programmes

The remaining programmes are all of recent origin. These include the sub-programmes on sheep and goats, bees, aquaculture, small-scale 'popular' plantain production, trees, coffee and cocoa; tropical roots and tubers; oil seeds; irrigation; small-scale agroindustry; and land use. In most regions these programmes are still in their formative stages, some more advanced than others (e.g. rabbit rearing in the western provinces of the country).

Key Issues in the Development of Urban Agriculture in Cuba

As urban agriculture has grown in Cuba, it has become apparent that there are several key factors that must be borne in mind.

Conservation and management of soil fertility

The productive potential of land available for food production is directly correlated with soil fertility. Although there are many factors that are important in fertility conservation, some require greater attention than others under actual field conditions. Central among these is the control of erosion – maintaining the structure and the physical condition of the soil. The intensity of rainfall in Cuba leads to the rapid leaching of soil nutrients and organic matter, and causes physical damage to soil structure and planting beds. It has proven essential to use a variety of agronomic techniques to protect soils from the effects of erosion. The periodic application of organic matter to soils, planting beds and containers is also indispensable, as nutrients lost or removed by the previous harvest must be returned or recycled, building the fertility necessary for future sowings (Peña, 1995). Finally, appropriate crop rotations and pest management systems adapted to local conditions have been essential.

Integrated pest and disease management

Pest and disease management is based mainly on cultural techniques and biological pesticides. The former rely principally on site selection and planting dates, crop varieties resistant to pests and diseases, adequate soil management, the elimination of alternate hosts of pests and diseases, crop rotations, elimination of infected plants, and thinning and pruning. During the spring and summer months when temperatures are at their hottest, seedling production is carried out in shade-houses, and the technique is employed of leaving clods of earth on the roots of the seedlings to be transplanted. INIFAT has developed totally organic seedling technology guaranteeing high-quality transplants with high yield potential, based on the local resources available in each area. This technique has reduced pest and disease problems due to the high level of vigour displayed by the transplants. The use of biopesticides and other biological pest controls is still being perfected, both in terms of guaranteeing an adequate and opportune supply, as well as with regard to application techniques. *Bacillus thuringiensis* and *Beauveria bassiana* have entered common use since the development and spread of artisanal production at the Centers for the Production of Entomophages and Entomopathogens (CREEs), and they are used against a variety of pests. *Trichoderma* spp. is used for the control of soil diseases. The introduction of new technologies such as neem (*Azadirachta indica*) extracts, and their artisanal and semi-industrial production, as well as of new bio-fungicides with demonstrated effectiveness, are critical for urban agriculture. Overall, food production in the cities is characterized by low pest and disease incidence, thanks especially to small plot sizes and the generous application of organic matter to the soil.

Crop–livestock integration

The nature of food production in cities pushes us towards high levels of production per unit area, facilitated by high levels of agrobiodiversity. The highest levels of productivity in organic farming are obtained when crop and livestock production are linked and fully integrated, a task which compels researchers, farmers and extensionists to work in the closest possible degree of collaboration. Already over half of the urban farms have effective linkages between crop and livestock production.

Urban Agriculture and Sustainability

The organic farming practices used in urban agriculture do not in and of themselves guarantee sustainability. To achieve sustainability all aspects of production must be rationalized and integrated, so that each component complements each other component, in such a way that each action leads to a better outcome at a lower cost.

The best example of this is found in the use of harvest residues and unmarketable portions as animal feed, in turn using the animals' manure to fertilize the crops. We have developed a set of indicators of sustainability to use in perfecting urban production systems. Among these indicators are the following:

- amount of organic matter collected, processed and applied;
- use of soil conservation methods to prevent erosion;
- degree to which seeds and starter-animals (i.e. chicks) are produced locally;
- degree to which varieties and breeds are adapted to local conditions;
- degree of crop–livestock integration;
- local water availability and soil moisture;
- efficiency of water use;
- amount of food produced/hectare per year;
- amount of food produced per capita;
- use of integrated pest and disease management systems;
- net profitability of production;
- degree of participation of farmers in training courses and extension activities.

By keeping track of these indicators we can monitor the development of urban agriculture. As the indicators improve over time, the sustainability of urban agriculture will be consolidated.

Conclusion

Over past few years the urban agriculture movement in Cuba has clearly demonstrated the food producing potential of cities. Today it is an important source of food for our urban populations. This has been made possible by the decisive effort put forth by urban farmers, and by the support given them by the government to carry out their tasks. The high-level of organization that has been achieved should make it possible to successfully implement the ambitious plans that are currently on the drawing board. We expect that in the near future urban agriculture will satisfy a high percentage of the food needs of our population.

Notes

1 Editor's note to the English edition: At the time of the final editing of this volume, an estimated 90 per cent of the fresh produce consumed in Havana is being produced in and around the city (Egidio Páez, pers. comm.).

2 One quintal equals 100 pounds.

The Quest for Ecological Modernization: Re-Spacing Rural Development and Agrifood Studies

Terry Marsden

Over recent years the sub-disciplines of rural sociology, development studies and the newly emerging social science of the environment have been attempting to address many of the same types of theoretical and empirical questions albeit from different starting points. The rural sociology of advanced economies has for a long time now drawn very productively from the field of development studies, even if both have remained quite distinct sub-disciplines with their own communities of interest and professional publication outlets (see Long, 2000). Similarly, the growth of work on the sociology of the environment, particularly in the European and North American context, has attempted to very much set its own broad agenda, but has done so in ways which have overlapped with the theoretical agenda of the more traditional rural sociology. Buttel (1996) and Frouws and Mol (1999) have traced the ways in which rural sociology acted as a 'formative' sub-discipline to the wider environmental sociology. And they question the extent to which these formative roles are gradually being reversed. The former's increasing ecumenical concern for aspects of rural nature, as almost a 'last refuge' in the process of urban and industrially based modernization, has meant that it has been the originator of significant theoretical and conceptual impulses into the wider and growing debates which have encapsulated environmental social science. While the latter, it might be argued, has taken on a more industrial and urban basis – addressing questions of ecological modernization, for instance, – it has also needed to refer to key authors in the older, parental disciplines of rural and development sociology (see Murphy, 2000). Indeed, all three sub-areas witness the creative engagement of several key authors who have their origins in rural sociology and anthropology. None of these authors would just regard themselves as rural sociologists per se; rather they are contributing to wider sociological and geographical debates concerning nature, space

Reprinted from Marsden T. 2004. The quest for ecological modernization: Re-spacing rural development and agri-food studies. *Sociologica Ruralis* 44(2), 129–147, Blackwell Publishing Ltd.

and environmental policy (see, for instance, the contributions to *The Environmental Sociology Handbook*, edited by Redclift and Woodgate, 1998; and Buttel, 2000).

Some may suggest that these developments represent something of a chaotic and disparate set of conditions which tend to diminish, rather than enhance, the true innovative character of the rural sociology of advanced economies. This paper will aim to demonstrate, alternatively, how a wider theoretical and conceptual landscape, based around environmental social theory, can help to assist contemporary rural sociology in progressing its agenda (Milbourne, 2003). Of particular relevance here is an assessment of rural sociology by Buttel (2001), where he makes the point that in the past decades work on aspects of regulation and globalization, for instance, has tended to be quite the reverse of the earlier theoretical developments of the 1970s and 1980s (what was then termed the 'new rural sociology'). He argues for more theoretical innovation to be undertaken. While the past decade or so has demonstrated quite a flurry of rich empirically engaged work (on areas of globalization, for example), actual theoretical development has reached, he argues, something of a hiatus; with various 'schools' tending to adopt a position along the actor-oriented–political-economy axis. At the very least we may have witnessed a period of more theoretical pluralism; which, in turn, may be perceived by some as reducing the power of meta-theory. Moreover, as Buttel also alludes, this can lead to the rather random/chaotic choice of micro-empirical case studies; with the suggestion that this can begin to lose sight of 'the big picture'. A key question here then is how can a more meta-theoretical agenda be established?

Ecological Modernization and More Sustainable Rural Development: Towards New Rural Eco-realities

However critical one might be about arguments associated with the rhetoric of sustainability, it is also the case that writers have pointed to the development, albeit fledgling in some cases, of a more ecologically modernizing agenda built upon a diverse theoretical base (see Buttel, 2000; Gibbs, 2000; Mol, 2000; Murphy, 2000). This is centrally associated with a European perspective on the development of clean industrial technologies, and the ways in which environmental coalitions and movements begin to affect reluctant state agencies. So far, they have only partially been applied to the rural sphere (see Frouws and Mol, 1999; Buttel, 2000), having been confined to the focus upon 'win–win' solutions in the business context (see Andersen and Massa, 2000). However, the degree to which we might be entering a new phase of modernization which would be much more autonomously 'ecological' is becoming a central theme in rural and agrofood studies (see Goodman, 1999, for instance), and the rural domain is becoming a central field for exploring the role and meaning of social nature debates (Milbourne, 2003). This could represent a new surge of creative and critical connections between environmental social theory as represented by the broad church of ecological modernization, on the one hand, and a more open and pluralistically engaged rural sociology on the other. It is to this exploration that this paper wishes to contribute.

Taking Buttel's theoretical challenge seriously, and at the same time as the arrival of more effective debates about a new (ecologically) modernizing process, it is necessary to address a central theoretical question. This in macro terms is: *to what extent are we seeing the arrival of a more autonomous ecologically modernizing process operating in advanced societies, and as part of this, through rural development trends specifically? Second, if we believe that this is a viable question, then what conceptual development and empirical realities does it suggest with respect to the rural sphere?* Taking some empirical and theoretical avenues in the three resource areas of agricultural restructuring, food supply chains and forestry, this paper adopts a positive view with regard to the first meta-question. It then attempts to demonstrate, through the definition of some conceptual parameters, how scholars might address the challenge this creates in tackling the second question.[1] With specific reference to these rural resource spheres it is suggested that we are witnessing the development of an ecological modernization process which is significantly different and autonomous in its character from the earlier industrial, 20th century modernization process. As Frouws and Mol theoretically delineate (1999, p271):

> The ecological modernization theory analyses possibilities for a process of 're-embedding' economic practices-in view of their ecological dimension-within the institutions of modernity. This modern 're-embedding' process should result in the institutionalization of 'ecology' in the social practices and institutions of production and consumption. The institutionalization of ecological interests in production and consumption processes, and thus the redirection of these basically economic practices into more ecologically sound ones, involves an 'emancipation' or differentiation of ecology. The differentiation of an ecological rationality and an ecological sphere, both becoming relatively independent from their economic counterparts, is the logical next step.

This process is analytically challenging in the sense that it is necessary at the same time to differentiate between ecological 'spheres' – that is, making analytical space for considering relatively autonomous ecological spheres so as to study how ecological actions and practices are becoming steadily institutionalized in the central institutions of modernity – but doing so without completely labelling these as distinct areas in society, that can simply be empirically identified. *The process of emancipation from the strictly economic sphere, and the gradual re-embedding of ecology in the institutions of economy, is a central aspect of ecological modernization, creating the spaces for an ecological as well as economic rationality*. This socio-ecological postulate requires detailed assessment in terms of its relevance to rural development – and it raises a theoretical potentiality for developing a more robust sustainable rural development paradigm (see Van der Ploeg et al, 2000; Marsden et al, 2003).

We should, of course, also recognize that this does not deny the maintenance of a dominant economic rationality, working as it may do to limit these new ecological, social, economic and political spaces. However, as some ecological theorists propose it does question the longevity of what Buttel (2000) refers to as the more established rational frameworks of the 'treadmill of production' and the 'growth machine' which have by no means completely disappeared. Arguably, however, they are in many places less in their ascendancy and subject to internal and external crisis tendencies (such as food scares, legitimization and ethical concerns, pollution incidents and long-term health problems, and not least the increasing and uneven global regulation of greenhouse gases), as well as deep structural tendencies which are seen as increasingly contradictory. Despite these internalized problems in the governmentality of a strictly economic rationality, it does not seem to reduce the possibility of strong reactive ('backlash') politics from taking ground back from the ecologically modernizing agenda. This is, for instance, one interpretation of the US Bush administration and its arguments against the signing of the Kyoto agreement, and the renewed faith in the domestic exploitation of oil reserves (Watts, 2002). Nevertheless, social-ecological debates and discourses are gaining ground in different guises and through different types of social, political and economic practices. While these may confront the former structural changes, associated with globalization of corporate capital, for instance, they are by no means simply marginal or subject to the marginalization effects of corporate states, firms and their social and political logics. Rather, and from a rural perspective, they may suggest a new centrality for many of the features of rural life that the industrially based modernization process tended to marginalize – for instance, aspects of agroecological development as part of rural development (see Rannikko, 1999; Jokinen, 2000), the development of decentralized and more sustainable rural communities as a central part of settlement hierarchies, and more mobile and information and communication technology-based sharing of experiences in rural and urban areas (Andersen, 2002). Indeed, we might suggest that one central element of ecological modernization is the very redefinition of the spatial and social balances between the more mobile urban and rural living experiences and frameworks; and about the realignment, more specifically, between nature, quality, region and locale, producers and consumers, for a more ecological rural resource base.

Some may see these notions as going too far. Moreover, we have to recognize that there are significant distinguishing features between what Christoff (1996) and Toke (2002) depict as forms of 'weak' and 'strong' ecological modernization; suggesting a caution about both the direction and pace of 'autonomous ecologism'. Nevertheless, we need to analytically explore these modalities between the economic and ecological rationalities, on the one hand, and the uneven development of 'weak' and 'strong' ecological modernization tendencies on the other. In addition, this challenges us to provide ecological modernization with a more robust theoretical basis, one which deepens the political-sociological perspective of ecological modernization such that the way forward would at least include not just:

> empirical debates over the potentials and limits of environmental engineering and industrial ecology, but rather to deepen the links to political-sociological literatures which will suggest new research problems and hypotheses (Buttel, 2000, p64).

We see here then a significant theoretical and empirical challenge both for rural sociology, on the one hand, and the broader field of environmental social science on the other. Both could benefit from at least engaging with the emergence of ecological modernization theory, if only to address the very longevity and resilience of the 20th century 'growth machine' and 'treadmill of production'. More optimistically such a deeper engagement could begin to set the coordinates for mapping Frouws and Mol's more 'deeper' ecologically embedded and conceptually autonomous model of ecological modernization.

Rural development becomes in this context a potentially rich sphere to assess these ecologizing tendencies, and to test the contingencies and frameworks involved in rebuilding a more viable and robust rural development perspective which at least begins to suggest how such ecological modernization notions might be more effectively progressed. Indeed, just as with the industrial mode of modernization (with its reliance upon a particular form of neoclassical economics), a new ecological paradigm also needs a viable, critical and normatively engaging social science. This is particularly the case with ecological modernization given, as we shall see below, the spatially variable and context dependent ways in which it actually expresses itself. What seems clear is that there is a lack of coherence in ecological modernization, one which can be partially or contradictorily adopted by national, regional and local governments; and one which may need particular confluences of strategic and local interests and actors to operate in new and innovative ways.

Looking at the recent rural sociological, and particularly the environmental social science literature over recent years, one begins to see this tendency being reported. One further key question is how far and fast will it travel, and how do we best equip ourselves as scholars to develop a growing relevance in understanding and mediating its required and contested knowledges?

There are some significant questions here. If we are to meet Buttel's theoretical challenge, it would suggest that we have to start looking at these bigger pictures. The 'new rural sociology' and political economy established and developed throughout the 1980s and 1990s was built upon the development of an intense and very effective critique of the late 20th century industrialization/modernization project (particularly as it related to the agrofood complex). We should perhaps now recognize that this challenge has now begun to change, for it is no longer sufficient to just critically examine the problems of such 'ageing regimes'. We need to be reconstructing as well as deconstructing models and frameworks which suggest *how things could work in different and more socio-ecological ways over space and time*. We need to visualize and articulate how actions and cases at one level can build up more broadly into significant and autonomous projects of change.

This paper aims to suggest a series of key concepts and theoretical formulations which could begin to build, not so much upon the diffusion of effort that some might argue we have witnessed, but on some useful integrative themes which could lead to a more robust and theoretically engaging of rural sociology with environmental sociology. In particular, it will be argued that this involves the need to re-problematize space and spatial relations (as socio-natural constructions) in our analyses, and to do so in ways which re-engage with the somewhat traditional sociological concepts of *community, regulation, consumption, exclusion, justice, bureaucratization, professionalization and expertise, associationalism* and *responsibility*. By doing this we can begin also to integrate some of the overdrawn dichotomies and debates between political economy and actor strategies and networks, social constructivism and realism, globalization and localism, economistically determined productionism and culturally confined consumptionism. It is argued that we need more engaging conceptual and theoretical formulations which help and guide us to not only make sense of the 'new ruralities' which confront us, but also to allow more *reconstructivist* as well as *critical interpretive* roles in both rural and environmental social sciences.

Exploring and taking forward ecological modernization debates may, therefore, be one way of meeting this growing need within rural sociology for improved theoretical engagement. As Frouws and Mol (1999, p286) conclude in their analysis of the ecological modernization of Dutch agriculture:

> Environmental sociology seems, in this respect, indeed capable of being a 'formative power' in the development of rural sociology. Its contribution is especially valuable to clarify the all-embracing impact of the environmental question on the technological and institutional reconstruction of agriculture, and to address its social, political and economic implications... This brief exploration also revealed, between the lines, the socio-political contestability and indeterminate outcome of ecological modernization as a political programme for agricultural change in the Netherlands.

Here, the paper outlines six key conceptual areas that are in need of development, which, it can be argued, give some pathways forward on which to continue to build such 'formative power'. These are explored here with reference to recent empirical research undertaken in the food, farming and forestry sectors on a variety of rural development projects.

Key Conceptual Starting Points: Empowering Social Ecologies

Environmental and territorial justice

A key feature of current patterns of rural development concern what seems to be greater amounts of economic and geographical uneven development. This is partly exacerbated by the gradual neoliberal shift, on the part of many nationstates, away from explicitly fostering more convergent, balanced, regional economic development. A key feature of extant rural and environmental arenas comes then in needing to address aspects of both territorial and environmental justice. The adoption of sustainable development goals cannot really be progressed unless they begin to deal with spatial uneven development, and particularly how local and regional conditions are incorporated into the analysis of how those broader and long-term conditions could be improved. A central question to consider is the extent to which scholars engage with the debates and assumptions of territorial and environmental justice. That is, having identified injustices in the uneven risk, distribution and quality of resources in space, how far should we go in formulating ways of reducing or compensating for this unevenness? For instance, it is quite clear from work on forestry and community in South Wales (see Marsden et al, 2003) that any attempts by the UK Forestry Commission[2] to encourage more participation and inclusion in the forested areas is constrained by the quite long history of growing social and spatially based deprivation of the nearby communities, for which the withdrawal of other state services and support structures has played a full part. Similarly, the growing social science research in the areas of food scarcity, and the identification of (both price and quality) 'food deserts' – often themselves hidden enclaves in larger, prosperous cities and regions, see Wrigley (2002) – demonstrates, on the one hand, the acute unevenness of rights to food consumption that the now corporate retailer-led supply chains have reproduced. The question is, however, not simply the issue of the empirical identification of these disparities. It also concerns how an engaging social science of rural development and food formulates alternatives which reduce and combat these. In the rural development field, while many of the grant-aided funding schemes emanating out of the EU still have (at least ostensibly) a strong territorial justice philosophy behind them (e.g. Structures funding, LEADER, Less Favoured Areas, etc.), the emphasis of a social capital and capacity logic governing local and regional allocations systems inevitably means that many rural groups and localities are failing to develop the critical mass to establish and capture such funding benefits.[3]

Hence, we can see here that progressing environmental and territorial justice questions are almost unavoidable in addressing these new developmental trends (see Economic and Social Research Council, 2001). For instance, what are the consequences of the further concentration of resources and economic development? What sort of trade-offs are possible or legitimate? How can injustices be compensated, monetarily and non-monetarily? How can a more multi-level-governance system in the rural development sphere (i.e. combinations of EU, national, regional and local policy platforms) progress a renewed set of regional and local convergence policies? Moreover, what are the social and political effects of persistent territorial injustices: in and through different rural spaces?

Community and association

Much of the social science of the environment literature (see, for instance, Irwin, 2001) and rural social nature debates have tended to so far underplay one of the traditional strengths of rural sociology: community. Somewhat surprising perhaps is that notions of community and association have failed to re-emerge as an important working and active mechanism between the social and the natural (but see Joseph Rowntree Foundation, 2002). Two examples illustrate this from our work on farming and rural development, and from the forestry and community work.

Alternative supply chains and rural development activities are, it seems, built upon new sets of associations and associational capacities of actors to engage in ways which shape both the social and the natural. Associational interfaces (often as emerging and contingent networks and chains) are both informal and highly significant in establishing trust, common understandings, working patterns, and forms of cooperation and co-optation between different actors in the supply chain. These differ from institutional interfaces which include state regulations and the support and services offered by rural economic development agencies (see Long, 2000). And, they are often crucial in generating and facilitating supply chain interfaces at a regional level – a key new spatial platform for the development of agro-food alternatives to take hold (see Renting et al, 2003). However, such interfaces are vulnerable to internal and externally generated disruptions. There is no inevitability that strong and mutually reinforcing associational interfaces will be reproduced over time. Furthermore, where they do not exist, or have broken down, it may take many years to rebuild relationships and working trust relationships to a point where regional or local actors – or actors acting at a distance across a supply chain – can create the conditions necessary to effectively and efficiently meet and relate to consumer demands. In many cases, in what we term 'short supply chains', these new associational competences are formed across the traditionally recognized producer/consumer arena. Indeed, reconnecting associational capacity across this former divide is part of the new sets of innovations that mark out the new modernization projects from the old. Evidence from European case studies suggests that sustaining rural development through the evolution of reconfigured supply chains must be based upon new combinations of both institutional support and associational development. Furthermore, these relationships must be able to adapt to internal and external shocks and pressures over time and space. Here, and again distinctively, there is no one model. A key question then is the degree to which these features will need to become more widespread if real aggregated rural development impacts are to be achieved, and how, if they are not apparent, can they be generated?

In the non-productive sphere of residential forest communities in South Wales, we also see how deep-seated local interpretations and impressions of community, and particularly of the marginalization effects of the State as part of community life, have a critical bearing upon the constructions and shapes of socio-natural relations and practices in that community (see also Rannikko, 1999). In short, the social character and construction of the community – in this case a socially rich place, but marginalized and peripheralized by the State – provides an important social prism through which nature is perceived and used. Hence socio-natural perceptions and practices emerge as an expression of the social construction of the community and, in this case, the particular incision of the state in this construction. In this sense what we can infer from this is that particular types or sets of socio-natural relations and practices cannot be simply 'read-off' from the prevailing sets of '(realist)' social and economic regulatory conditions. Neither, however, as social constructionists may propose, can they just be rendered as varyingly 'co-constructed' within environmentally related practices and social contexts (Irwin, 2001). The residents in the community are not just free agents in their constructions of natural relations. Neither is the forest a neutral natural actant operating in a completely natural setting. Both nature (in this case the forest) and the people are actively engaging in broader socio-political conditions which, in turn help to shape the particular types of socio-natural relations in this type of local context. While such a postulate suggests that there is an inherent partiality about the two earlier approaches. What needs to be added to both conceptions is an empirically embedded understanding of how the natural becomes an active ingredient in the continual process of community construction.

Exclusion and empowerment

While aspects of rural social exclusion have become a vibrant topic of concern, especially amongst rural geographers (see Cloke et al, 2000; Shucksmith, 2000), the emphasis of this work has thus far been largely upon the identification of exclusionary practices in different social, economic, institutional and domestic rural arena. One further and important aspect, however, concerns the ways in which communities, different actors and agencies can become more empowered, and to do so in contexts which are ecologically as well as socially sustainable. In our UK forestry communities we witness a long historical process of disempowerment brought about by both the productivist priorities of the mining and forestry sectors and, in addition, the gradual marginalization of much of the community by labour markets and the state authorities. Here disempowerment is multifaceted, and it is the combination of these *marginalization histories* which provide the backdrop for any change of forestry commission policy in terms of enhancing community and sustainable development. The exclusion-empowerment equations operate differently between and through communities and they provide a key mechanism in establishing the social landscape upon which new, more ecological forms of modernization could take hold. Indeed, they provide a major way in which ecological modernizing principles can in themselves become marginalized and obscured in the face of what are seen to be more short-term employment imperatives.

A further, if separate element of exclusion and empowerment comes in terms of the market and consumer exclusions operating in the conventional food supply system. Here we see two key processes at work which deserve much more attention in progressing a more ecologically modernizing agenda. These concern the exclusionary tendencies based upon price, quality and location encouraged by the corporate retailers in the operation of their food chains (see Competition Commission, 2000). This is generating a major feature of the 'new food polities', with consumer agencies adopting exclusionary arguments as well as food quality arguments in their political articulations with government authorities. The operation of what is called in the trade as 'price flexing' – whereby the big retailers purposely vary their grocery prices in the light of local competitive conditions rather than being related to actual costs – has become widespread in the UK. Even the conservatively written recent

Competition Commission report of the national government concluded that where the big corporate retailers were practising this, it tended to operate against the public interest. Customers tend to pay more at stores that do not face particular competitors than they would do if those competitors were present in the area. In many of the marginalized working class areas of the urban and rural UK, these monopoly retailing arrangements are now commonplace. Hence we see here that there is a real need to link the particular corporate and institutional practices with local empowerment and exclusionary conditions – in space. In many of the debates so far – both academic and public policy – these linkages in space have been at best blurred. Indeed, the spacing of exclusionary practices and their links to corporate strategies has been neglected. It is not so much about the identification of 'food deserts' as understanding the interfaces of corporate strategy and local consumption in their varied spatial contexts. As this example shows, what we witness in many areas are competition practices going in reverse. With major retailers being able to create almost 'monopoly consumption spaces' in which they can raise prices, beyond their relationships with 'true' costs. Keeping other retail competitors out as well as harnessing loyal and recurrent consumers in to their stores becomes a central mechanism *in* the territoriality of exclusive food consumption in the British context.

A third arena of exclusion/empowerment concerns those at the other end of the food supply chain – the primary producers. Despite all the government rhetoric about the need to abide by the laws of fair trading and European competition policy, many farmers and many processors find themselves excluded from the often more lucrative retailer-led food markets. For those that do gain entry, the degree of informal control over their operations severely constrains their 'room for manoeuvre'. In many ways these are the newly created forces of subsumption operating in the retailer-led chains; whereby pricing and conditions can be placed upon producers and processors in ways which are seen to be 'consumer-led', but really emerge from the day-to-day management of these supply chains by the category managers of the retailers. With exclusion or relative empowerment in this regard, therefore, we see also the creative development of social and economic dependencies operating between different sets of actors in the supply chain. Local rural and agricultural spaces are, therefore, no longer controlled at a distance by the corporate input suppliers (i.e. associated with concepts of appropriation, substitution and subsumption of production). Now it is more variably conditioned by the downstream merchant (rather than industrial) retailer elites who engage groups of consumers and governments in their powerful networks. Hence, primary production becomes something of a backwater and 'dirty' activity which needs to be 'cleaned up' by the state and corporate retailers on behalf of the public.

We see here, then, through these examples how exclusion and empowerment strands are a critical integrating mechanism for bringing together the social, economic and institutional construction of power, both in and through rural (as well as urban) spaces. This is cross-cutting both vertically through supply chains and laterally through community/institutional interfaces.

Consumption and production: socially and culturally reconstructing the commodity

While considerably more emphasis has been placed upon understanding the relationships between production and consumption, and particularly the ways in which the very fabric of food fuses both natural and social hybridities, there needs to be more attention given to the ways in which the hybrid social and natural relations surrounding food are governed, empowered and used. While accepting that there has been something of a (somewhat overdrawn) conceptual distinction made between the more political economy-inspired analysis of production and the more culturally inspired consumption studies, there is a clear need to explore how new alliances, relationships and metabolic equations can be brought together in ways which progress the understanding of alternative food networks or chains. Also, we need to know much more about how these both use and travel through space. Our recent European evidence suggests high levels of spatial variability between different rural regions in the setting up and sustenance of alternative supply chains (Renting et al, 2003). These variabilities are particularly affected by the type and degree of institutional support, via, not just the national state, but regional and knowledge and skill-based agencies, and by the highly context-dependent types of associational involvement from a variety of different actors. It is clear that the innovation patterns, the skills bases and the degree to which such initiatives can utilize and exploit the 'territorial worth' of their localities and regions are all critical factors. These factors show that aspects of space, quality convention, nature, and agricultural and food socio-technical practices (the particular ways of cutting, curing, salting and carving of meats, for instance) come together in rural spaces. Moreover, many of these initiatives also reconstruct important new co-locational alliances with specific groups of consumers. Many consumers, for their part, are increasingly searching for 'something else' other than the standardized or indeed mass-produced specialized types of food product. The consumption experience, often involving direct contact with the producer or the seller becomes an important ritualistic consumption practice.

However, what marks these alternative food chains out from the conventional system is by no means their face-to-face nature necessarily. In some of the more maturer quality supply chains we see the development of spatially extended networks, which are selling brands, labels and seriously commodifying their culinary repertoires (e.g. Parmigiano Reggiano Cheese). They are still categorically alternative, however, in that they have done and do re-equate nature, space, socio-technical practices and quality conventions in ways which make it impossible to replicate these outside that network. These then are the new ecologically deepened supply chains, and to describe and understand them requires much more than a recourse to such generalized notions of mutual or reciprocal metabolics. Rather, it requires a concerted effort to understand the theory and practices of the actors – producer, consumers and exchange actors – who mobilize and animate/demarcate such networks (see Verschoor, 1998, for instance). These new food networks are now a common occurrence and in many regions are by no means marginal to the conventional system. In Northern Italy then we see a concentration of quality food networks, while in Germany and The Netherlands, new alliances are more associated with agri-tourism ventures and nature and landscape management. Food, as a culturally hybrid entity, becomes unevenly embedded into the fabric of new rural development practices; and new synergies become developed between food, agricultural practice, consumption practices and associational and institutional arrangements.

Understanding the wealth and worth of these series of micro-social practices and, still more, assessing what in more generalized terms they 'add up to' is a major empirical and theoretical task, for which scholars have only recently embarked. It is clear, however, that the volatilities in the consumption/production relations associated with the conventional systems, will have pervasive effects and interactions upon the competitive spaces that these alternative food supply chains operate in. This is highly contingent, not just upon some vague notions of consumer culture or sovereignty. It is also centrally conditioned by the contested and institutional ways in which the 'consumer interest' is continually constructed – and by whom. Such analytical progress will not rely just upon a realization that nature and society are hybridized in food. The issue is how, where and by which powerful/non-powerful actors? Food as a realm of governance and social and political regulation is not contradicted by more socially constructivist processes. These need to be put together, not least because institutional actors and agencies are part of that constructed and contested process. Somehow, we need to understand how alternative food networks not only get formed, but then get demarcated and maintained as a socio-competitive dynamic. They are not static events.

Corporate responsibility and accountability

The past two decades have witnessed a significant growth in research work on the globalization and regulation of agribusiness and the workings of multinationals (for a review of the commodity systems approach, see Friedland, 2001). This has been a major development of the discipline of rural sociology, and it has emerged as a clear critique of industrial modernization in the agro-food sector. In postulating aspects of ecological modernization, however, we also now need to consider and critically assess how business relationships (with each other, with consumers and with local communities) are changing as a result of a number of significant forces. These include: changes in the regulatory frameworks; the globalization of supply chains and the increasing mobility of capital and knowledge; the application of ICT to radically restructure certain markets, industries and places; changing patterns of consumption and falling consumer trust in existing forms of corporate and government communications; the emergence of civil society groups and global protest movements and a realization that companies may be more vulnerable to pressure for change than entrenched or undemocratic governments; the fragmentation of local communities and constructions of community; the pressure from the investment community in the form of the growing ethical investment movement; and the pressure from insurers who see the reduction of environmental damage and social conflict as an important way for companies to reduce levels of risk.

These reconstituting forces are, in turn, reshaping the relationships between firms, governments and 'communities of interest'. Among the actors there are key constituencies who will help to shape the dynamic and developing relationships both within their actor-spaces and between themselves and other actors. From the point of view of business it is now more essential (albeit to varying spatial and sectoral degrees) that these relationships are constructed and constantly reconstructed in ways that help to ensure its longer-term survival. These can be depicted in Figure 20.1. However, neither the effects on businesses of the processes of change that are identified here will not be even, and nor will be the impacts on the 'communities of interest'. *What is necessary in research terms then is to theoretically and empirically understand the richness, complexity and contestability of business responses to, and the management of, its environment.* In short we need new constructed models of (potentially autonomous) business behaviour and relationships which are embedded in the social, environmental and political contexts which they are attempting to shape.

So far environmental and rural sociologists have tended to avoid these ventures, leaving it to the environmental economists and ethical marketing specialists to engage in the tracing of these new patterns. For instance, such discipline-specific research is pursuing the following lines:

- The inclusion of sustainability and social responsiveness within corporate accounting and reporting practices, and its relationships to the growing ethical

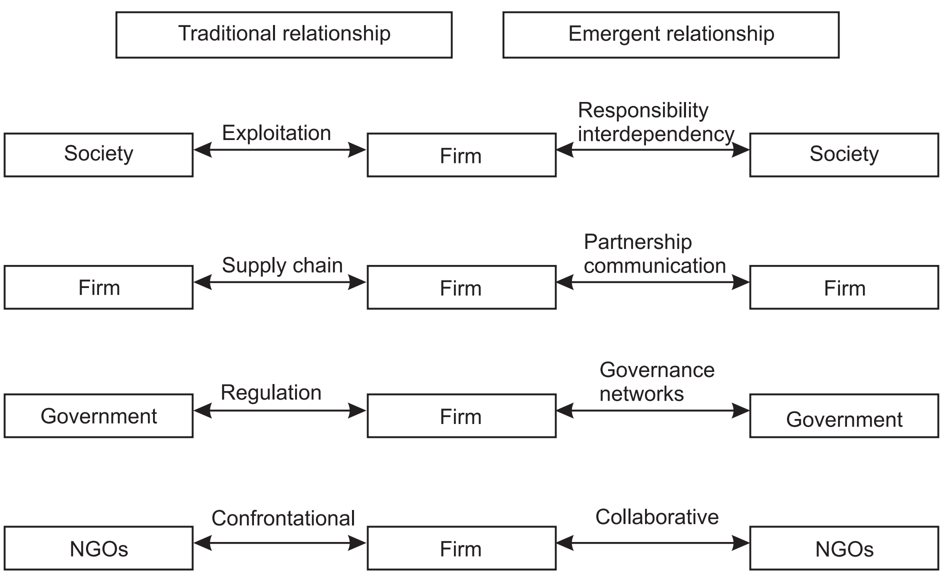

Figure 20.1 *Changing relationships between key actors*

investment industry is typically being researched within the accounting and finance disciplines (e.g. Gray et al, 1995).
- Changing consumer demand for ethically and environmentally acceptable products and the response of companies to demands for such products, new information and new marketing approaches is typically being researched by the marketing and economics disciplines (e.g. Menon and Menon, 1997).
- The evolution of environmental and social regulation and its impact on firms is typically researched within the legal and public policy discipline (e.g. Garrod, 2000).
- The implications of sustainability in terms of industry structure and infrastructure is typically a focus of research in the planning, geography and public policy disciplines (e.g. Ogu, 2000).
- And, the influence of global capital flows and governance standards is primarily researched within the law, finance and international relations disciplines (see Brack, 1995).

Yet, in all these areas environmental social science, and more specifically rural social science, has a potentially important role to play, particularly in understanding how these changing business, government and community relationships are spaced and re-spaced. In the food sector, for instance, the contested competitive spaces between conventional and alternative supply chains is occurring in a broader context of a reduced reliance simply upon legal compliance as a justification and legitimization of actions. In this sense *de jure* regulation is not enough. Also, there is a broadening amongst many firms of the 'stakeholder concept' whereby companies are increasingly having to respond not just to customers and investors, but also those with a physical stake in their actions, including the communities within which they operate and NGOs representing myriad interests (Polonsky, 1995). We see this empirically, for instance in the redefinition of UK Forestry Commission policy and the new sets of relationships developing with government agencies. Moreover, consumer groups and governments have traditionally championed consumer rights in terms of choice, value and safety of products. Yet concerns over the sustainability and social responsiveness of businesses has led to an increased interest among stakeholders about the methods and consequences of production (Peattie, 1999). This is most easily observable within the food industry, where concern is centred on issues relating to production practices – such as the use of chemicals, the use of genetically modified organisms and the constituents of animal feedstuffs, pollution and the destruction of habitats. These trends suggest, at the very least, a set of key research questions:

- How are changing patterns of demand leading to the development of more sustainable and socially responsible strategies, products and technologies?
- What types of new market and institutional structures (e.g. supply loops and networks) will develop in response to product take-back, as businesses are required by legislation and consumer pressure to become even more accountable for the life cycle of their products?

- What opportunities will arise for the restructuring of industries around new business models and types of production systems and technologies?
- How will business-to-business and business-to-consumer relationships change if a service-based economy (i.e. through leasing, take-back and service arrangements) begins to replace the traditional exchange of physical goods?

To begin to answer some of these questions will require the development of new social and regulatory 'designs' around which we can begin to explore the richness and complexity of business/environment relationships. Such an endeavour will need to take us far beyond the much more established and somewhat retrospective 'tracking' of multinational commodity flows. Moreover, we should put aside the rather binary question of whether firms will or will not ecologically modernize. Rather, we should explore both *what* is and *what might be*.

Regulation and bureaucratic professionalization

It is important to recognize that the story of environmentalization in the rural field over the past two decades has been one in which a particular form of Weberian bureaucracy has been increasingly prevalent. We need to recognize both why this has been the case and, conversely, why it is not necessarily the only model in town (see Marsden et al, 2001). I have, in the context of the agricultural and food sector in Europe (post-BSE) termed this more specifically the *hygienic mode of regulation*. As the industrial mode of food supply has become even more crisis-ridden, the state has attempted to largely 'correct' this by setting up highly professionalized and bureaucratized forms of environmental safeguards and instruments. This has also been conducted in 'the interests of the consumer', as a way of governments seeking to protect their interests at the same time as allowing corporate industry the ability to exploit new markets. The growth of a profound regulatory burden, as a response to the crisis in the industrial mode of agro-food, tends therefore only to strengthen the economic and political power of established agroindustrial interests (including the large retailers and manufacturers). Both private and public forms of regulation are used to 'clean-up' the industrial system in the ostensible 'public interest'. Such *schematization* holds the added consequence of further constraining the real potential of integrated agricultural development as well as providing new regulatory barriers to market entry for many smaller producers and processors. For consumers, it allows the disconnections and distanciations between production and consumption to conveniently continue: with an encouragement that 'safety' comes before sustainability. A growth industry for many environmental scholars has been found in the evaluation of such *hygienic schemata*.

These processes have tended to break, or at least 'fracture' the environmental and rural development question into specific boxes, projects and schemes; making it more difficult to make holistic connections (as associated with agroecology for example, see Sevilla Guzmán and Woodgate, 1998). As a result it has been difficult for many actors to construct viable and integrated alternatives, or to harness the necessary spatial, natural, regional and knowledge-based resources necessary to progress *real* rural development options.

The broader field of rural development, as well as that of agro-food, has also become increasingly populated with project managers, consultants, exchange agents, etc., such that a profession has been established to which some are excluded. Moreover, current priorities of national governments concern the reconciling of the demands and risks of the 'careful consumer'. In the agro-food sector this is largely done by assembling a bureaucratic-hygienic apparatus – itself something of a new compromise between governments and capital – in order to stave off a further and potentially deeper consumer-led legitimization crisis in the old industrial system as a whole. In this context 'primary producers' – those nearest to the natural land-base – are continually disempowered. This has most recently been exposed in the UK with the government's responses to the 2001 foot and mouth outbreak, where regulatory controls on the movement and selling of livestock is hastening the demise of the smaller farms through the closure of livestock markets. Indeed the paradox of the story to eradicate BSE and other risks from the industrial food chain has been that the regulatory responses to it have further embedded industrial systems of supply, processing and retailing in the livestock and meat sectors.

There is a need, therefore, for rural social scientists to contest these regulatory modes and to apply other, for instance, agroecological and food ecological models to rural realities. This will require us to explore the contradictions and practices embedded in the different modes of environmental policy discourse, and for us to challenge the specificity of environmental expertise and professionalization. How can a more holistic food ecology be created? And, what novel forms of regulation would this require? Is the bureaucratic–hygienic mode sustainable over time and space? And what barriers does it place upon achieving real ecological modernization? For instance, while the current agro-environmental policy and rural development discourse continues apace in the European Commission, we see in Finland, the rapid structural concentration of farms occurring as a result of the CAP. The surface waves of ecological modernization discourses often seem to obscure the deeper countervailing currents of structural changes in the agro-food sector.

Conclusions: Looking Through the Environmental Maze

Past analyses in rural sociology, and to a large extent in environmental sociology more generally (see Redclift and Woodgate, 1998), have been built upon sophisticated and critical interpretations of the (agro-)industrial modernization project. In rural development terms, for example, this has focused upon challenging the prevailing economic notions of scale, critical mass, centralization, globalization and marginalization that this model has clearly engendered. Ecological modernization, in all of its shades, nuances and theoretical flaws, at least brings forth a new question. That is, how could/should the contested relationships between civil society, the state and the market be rearranged in ways which would usher in different types of autonomous development which would incorporate ecological worth?

A 'new age' of ecology, however, has begun in a slow, fledgling and uneven way, and it demands significant comparative analysis. It is argued here that it does, however, have some real intellectual purchase, and that part of this allows us to overcome some of the theoretical rigidities and obstacles of the past. Furthermore, part of its value is that it brings the need for an enhanced spatial sophistication and problematization back into a central arena in rural sociology. In addition, it opens the door to more theoretical pluralism, debate and progress, moving beyond binary social constructivist versus realist debates, structure and agency, and macro and micro concerns. Hence, the brief accounts of some key concerns are elaborated here as examples of how a stronger social-environmental and rural sociological enterprise might be forged. The concepts are by no means exclusively the preserve of either sub-discipline. However, they represent central critical connections or bridgeheads through which such disciplines and theories could be progressed.

An attempt has been made here then to set out some of the cardinal conceptual reference points and dialectics which are currently relevant for taking forward a more productive and creative engagement between ecological modernization theory and rural sociology. These are partly empirically grounded as well as theoretically constructed arguments and, as such, they deserve much more expansion, debate and consideration than is feasible in this short paper.

However, one of the fruitful opportunities such an exercise begins to present is the possibility of reassembling conceptual frameworks in ways which integrate nature and space within the broader political economy of local, national and international ruralities. As we see from the discussion above, many of the current environmental discourses and regulatory frameworks tend to fracture and fragment such integrative endeavours in such ways as to create false divisions of professional labour and interests between different communities of interest (including academics, policy officials, environmental NGOs, consultants and a whole range of 'project managers' who are now engaged in competitively progressing rural development initiatives). This makes integration in ecological policy development and implementation all that more difficult, and it leads to the driving out of a more radical consideration of alternatives (or 'deeper' form of ecological modernization) by the urgency of meeting bureaucratically applied performance measures and indicators. Hence, the more holistic and critical development of environmental and rural social science is now a central task in *creatively engaging with what might be, as well as what is*. For instance, to not only accept that ecological modernization is a highly contested and partial process, but to explore its further empirical and theoretical potentialities in creating the spaces for autonomous action, institutional reforms and development. The conceptual starting points outlined here are in this sense 'middle level' concepts which can start to address this task. We should remember that the agroindustrial modernization project has developed an elaborate and justificatory social science with which to legitimize and institutionalize itself; yet an equivalent rural social science for ecological modernization and rural development is still very much in its infancy, and liable to marginalization and dependency rather than autonomy and development.

Notes

1 The arguments developed here draw upon three research projects being conducted by the author and several colleagues (including Paul Milbourne, Jon Murdoch, Kevin Bishop). The first was entitled *Innovation and quality in the food chain: strengthening the regional dimension* funded by the Economic and Social Research Council. The second is entitled *The Socio-economic impact of rural development policies: realities and potentials* funded by the EU; and the third related to an ethnographic study, *Forestry, community and land in the South Wales Valleys* funded by the UK Forestry Commission. The early results emanating from these projects are containedin recent articles (see Murdoch et al, 2000; Bishop et al, 2001; Marsden et al, 2003).

2 The Forestry Commission is the main state-sponsored body for owning and managing forest lands in the UK.

3 Some recent and important evidence suggests that even those EU schemes which are associated with attempting to alleviate rural territorial disparities (such as Less Favoured Areas policies) are also tending to increase rather than decrease them. Shucksmith (2003) reported that richer and more prosperous regions tend to capture a higher proportion of such EU funds.

Editorial Introduction to Volume IV

Jules Pretty

Food Systems Overview: The Wider Policy Context

By the early 21st century, several things had become clear from evidence on the recent spread of agricultural sustainability in both industrialized and developing countries:

- Many technologies and social processes for local scale adoption of more sustainable agricultural systems were increasingly well-tested and established.
- The social and institutional conditions for spread were less well understood, but had been established in several contexts, leading to more rapid spread during the 1990s–early 2000s.
- The political conditions for the emergence of supportive policies were the least well established, with only a few examples of significant progress on reform.

Sustainable agriculture has been shown to be able to contribute to increased food production, as well as makes a positive impact on environmental goods and services. Clearly much can be done with existing resources, but a wider transition towards a more sustainable agriculture will not occur without more explicit external institutional and financial support. There are always transition costs in developing new or adapting old technologies, in learning to work together and in breaking free from existing patterns of thought and practice. It also costs time and money to rebuild depleted natural and social capital.

Most agricultural sustainability improvements in developing and industrialized countries occurring in the 1990s and early 2000s appear to have arisen despite existing national and institutional policies, rather than because of them. Although almost every country would now say it supports the idea of agricultural sustainability, the evidence points towards only patchy reforms. Only three countries have given explicit national support for sustainable agriculture: Cuba has a national policy for alternative agriculture; Switzerland has three tiers of support to encourage environmental services from agriculture and rural development; and Bhutan has a national environmental policy coordinated across all sectors. But even in these countries, there remains much to do.

Several countries have given sub-regional support to agricultural sustainability, such as the states of Santa Caterina, Paraná and Rio Grande do Sul in southern Brazil supporting zero-tillage, catchment management and rural agribusiness development, and some states in India supporting participatory watershed and irrigation management. A larger number of countries have reformed parts of agricultural policies, such as China's support for integrated ecological demonstration villages, Kenya's catchment approach to soil conservation, Indonesia's ban on pesticides and programme for farmer field schools, Bolivia's regional integration of agricultural and rural policies, Sweden's support for organic agriculture, Burkina Faso's land policy, and Sri Lanka and the Philippines' stipulation that water users' groups be formed to manage irrigation systems. In Europe and the US, a number of agri-environmental schemes have been implemented in the past decade, though their success has as yet only been patchy.

A good example of an integrated programme comes from China. In March 1994, the government published a White Paper to set out its plan for implementation of Agenda 21, and put forward ecological farming, known as *Shengtai Nongye* or agroecological engineering, as the approach to achieve sustainability in agriculture. Pilot projects have been established in 2000 townships and villages spread across 150 counties. Policy for these 'eco-counties' is organized through a cross-ministry partnership, which uses a variety of incentives to encourage adoption of diverse production systems to replace monocultures. These include subsidies and loans, technical assistance, tax exemptions and deductions, security of land tenure, marketing services and linkages to research organizations. These eco-counties contain some 12 million hectares of land, about half of which is cropland and, though only covering a relatively small part of China's total agricultural land, they illustrate what is possible when policy is appropriately coordinated.

What we do not yet know is whether progress towards more sustainable agricultural systems will result in enough food to meet the current food needs in developing countries, let alone the future needs after continued population growth and adoption of more urban and meat-rich diets. But what is occurring should be cause for cautious optimism, particularly as evidence indicates that productivity can grow over time if natural, social and human assets are accumulated. A more sustainable agriculture that improves the asset base can lead to rural livelihood improvements. People can be better off, have more food, be better organized, have access to external services and power structures, and have more choices in their lives.

But like all major changes, such transitions can also provoke secondary problems. For example, building a road near a forest can help farmers reach food markets, but also aid illegal timber extraction. Projects may be making considerable progress on reducing soil erosion and increasing water conservation through adoption of zero-tillage, but still continue to rely on applications of herbicides. If land has to be closed off to grazing for rehabilitation, then people with no other source of feed may have to sell their livestock; and if cropping intensity increases or new lands are taken into cultivation, then the burden of increased workloads may fall particularly on women. Also additional incomes arising from sales of produce may go directly to men in households, who are less likely than women to invest in children and the household as a whole. New winners and losers will emerge with the widespread adoption of sustainable agriculture. Producers of current agrochemical products are likely to suffer market losses from a more limited role for their products. The increase in assets that could come from sustainable agriculture may simply increase the incentives for more powerful interests to take over. Not all political interests will be content to see poor farmers and families organize into more powerful social networks and alliances.

Many countries also have national policies that promote export-led agricultural development. Access to international markets is clearly important for small farmers, and successful competition for market share can be a significant source of foreign exchange for poorer countries. However, this approach has some drawbacks:

- Poor countries are in competition with each other for market share, and so there is likely to be a downward pressure on prices, which reduces returns over time unless productivity continues to increase.
- Markets for agrifood products are fickle, and can be rapidly undermined by alternative products or threats (e.g. avian bird flu and the collapse of the Thai poultry sector).
- Distant markets are less sensitive to the potential negative externalities of agricultural production and are rarely pro-poor (with the exception of fair trade products).
- Smallholders have many difficulties in accessing international markets and market information.

More importantly, an export-led approach can seem to ignore the in-country opportunities for agricultural development focused on local and regional markets. Agricultural policies with both sustainability and poverty-reduction aims should adopt a multi-track approach that emphasizes: (1) small farmer development linked to local markets; (2) agribusiness development – both small businesses and export-led; (3) agro-processing and value-added activities – to ensure that returns are maximized in-country; (4) urban agriculture – as many urban people rely on small-scale urban food production that rarely appears in national statistics; and (5) livestock development – to meet local increases in demand for meat (predicted to increase as economies become richer).

A differentiated approach for agricultural policies will become increasingly necessary if agricultural systems themselves are to become more productive and sustainable whilst reducing negative impacts on the environment. This will require wider attention to exchange rate policies, trade reforms, domestic agricultural prices, input subsidies, labour market reforms, education and investment in schools, rural infrastructure, secure property rights to water and land, development of institutions for resource management, and substantial investments in agricultural research and extension. At the same time, the environmental costs of transporting food are increasing, and in some countries are greater than the costs arising from food production on farms, suggesting that sustainability priorities need to be set for whole food chains.

Part I: Ethics and Systems Thinking

Aldo Leopold was a conservation biologist made famous by both his writings in *A Sand County Almanac* and his transformation of a farm at Baraboo by the Wisconsin River. 'The Land Ethic' is a short essay from the late 1940s that sets out his views on human relations with the land – which he takes to include the community of soils, waters, plants and animals. In the face of damage to all of these caused by human action, he sets out the need for a mode of guidance. 'An ethic', he says, 'ecologically, is a limitation on freedom of action in the struggle for existence. An ethic, philosophically, is a differentiation of social from antisocial conduct.' This antisocial conduct partly derives from the narrow way we tend to view the land relation, namely a strictly economic one, 'entailing privileges but not obligations'. The language of the essay is at times stilted and dated, but the timing was impeccable. Ecological systems are so complex that their workings may never be fully comprehended. Yet we often act as if we know enough. Leopold further explores the dilemma of environmental education and the difficulty of changing mindsets. The problem with formal education, he says is that 'we have more education but less soil, fewer healthy woods and as many floods'. The Land Ethic was visionary and, with his other writings, Leopold was able to set out what needed to be done to change the way we all think and act.

One of the world's most notable and early thinkers on sustainability in agricultural systems was Masanobu Fukuoka, who wrote the concise and thoughtful *The One-Straw Revolution* in 1978. As a Japanese farmer himself, Fukuoka put into practice his own principles for natural farming. His concerns were this as he looked across to his neighbour's field: 'these rice fields, which have been found continuously for over 1500 years, have now been laid waste by the exploitative farming practices of a single generation'. This short chapter sets out Fukuoka's four principles of natural farming: no cultivation of the soil, no chemical fertilizer or prepared compost, no weeding by tillage or herbicides and no dependence on chemical intervention. The result is a permaculture of diverse crops, alongside dragonflies, moths, bees, spiders, frogs, lizards and many other small animals. This for him is the balanced rice field ecosystem.

Richard Bawden then develops the theme of knowing systems and the environment in the third article. Once again, the problem lies in how we have come to risk the world on the back of great recent achievements in economic and technological development. The chapter focuses on systems, both hard and soft, and on coming to know. Our quest, says Bawden, in seeking to come to terms with sustainability, must start with learning. What do we think we mean when we use terms like development and sustainability? We have made the world as it is, and so it is up to us collectively to make meaning through our learning. In a state of denial, about how bad circumstances are, we are going to need to devise different ways to think, interact and act very quickly. An important contrast centres on how we conceptualize systems ideas, and thus bring some cognitive coherence to bear on a complex world. Earlier pioneers of systems thinking focused on cybernetic regulative processes that maintained steady states, and many ideas about resilience and adaptation have since been developed. But strangely, systems ideas in the social sciences have seen declining support in recent decades. Another conceptualization, however, centres less on systems in the world, and more on systems of cognition, in which inquiry about the world is the soft system that can be both revealing and transformative. In this way, learning becomes less about the acquisition of knowledge, and more about the transformation of experience, whereby knowledge is fluid, being created, recreated and used by individuals as they seek to make sense of the world. The quest for sustainability focuses on new types of engagement between people with their different worldviews and paradigms, and the world about us.

In the fourth chapter, philosopher Paul Thompson explores the nature of agricultural sustainability. Philosophers spend a large part of their time scrutinizing words and concepts, attempting to get clear on what they mean, and on the implications of their meaning for human endeavours. Philosophy can help clarify hidden assumptions in alternative definitions and approaches to sustainability. Current usage reveals two main substantive approaches, resource sufficiency and functional integrity, as well as widespread non-substantive usage intended to promote social action. Although accounting-based resource sufficiency approaches have been the main focus in technical approaches, functional integrity approaches may be more transparent with respect to value judgements that inform the notion of sustainable systems. The 'paradox of sustainability' arises because substantive, research-based approaches to sustainability may be too complex to effectively motivate appropriate social responses. Nevertheless, debate over the meaning of sustainability can stimulate a fuller appreciation of the complex empirical processes and potentially contestable values that are implicated in any attempt to accomplish sustainability in agriculture.

Robert Chambers' *Managing Canal Irrigation* was published in the 1980s at a time when agricultural practices in many parts of the world were seeking to develop methods to offset the inherent personal and institutional biases that prevented clear understanding of conditions as poor people experienced them. Canal irrigation systems represent a particular type of system in which the poor and the tailenders are often forgotten. This chapter focuses on learning and mislearning, which at that point of time had not been the subject of much research. Yet it is how beliefs are formed and sustained that influences what professionals see. Irrigation systems in Gujarat and Madhya Pradesh are analysed, and these reveal the need for open learning systems. One problem is that trial areas receive special treatment at the beginning of projects, which are then assumed to represent the same conditions for all farmers. These special project areas are much visited and reported on, and again give the misleading impression that the same kinds of success are occurring everywhere. Privileged water, supplied at the cost of other parts of a system, is another special problem, appearing again to illustrate to unthinking professionals that their projects are successful.

Part II: Participatory Processes

In the first article, drawn from the seminal 1989 book *Farmer First*, Robert Chambers discusses the reversals necessary to put farmers' knowledge and capacities at the heart of agricultural transformations. For decades, agricultural research and extension institutions have used a transfer-of-technology mode of working, with farmers and their communities simply as recipients of technologies and practices developed on research stations. A farmer first approach requires professionals to adopt different attitudes and behaviour, becoming, for example, convenors, catalysts, advisers, travel agents and supporters of farmers' own analyses, choices and experiments. The complex, diverse and risk-prone environments of many developing country contexts are not well-suited to homogenous technologies, however effective they have been on research stations. They require that professionals reverse past practices, and encourage farmers to conduct their own analyses and experiments, thus adapting and fitting technologies to their own situations. Such reversals of 'normal practice' also require institutional change, with policies and institutions needing to facilitate such efforts. As Chambers said, the stakes are high, and a decade and a half after this chapter was written, they remain disturbingly high for millions of people and their environments.

There is a long history of participation in agricultural development; and a wide range of development agencies, both national and international, have attempted to involve people in some aspect of planning and implementation. Two overlapping schools of thought and practice have evolved. One views participation as a means to increase efficiency, the central notion being that if people are involved, then they are more likely to agree with and support the new development or service. The other sees participation as a fundamental right, in which the main aim is to initiate mobilization for collective action, empowerment and institution building. As a result, the terms 'people's participation' and 'popular participation' are now part of the normal language of many development agencies, including non-governmental organizations (NGOs), government departments and banks. It is such a fashion that almost everyone says that participation is part of their work. This has created many paradoxes. The term 'participation' has been used to justify the extension of control of the state as well as to build local capacity and self-reliance; it has been used to justify external decisions as well as to devolve power and decision making away from external agencies; it has been used for data collection as well as for interactive analysis. In this chapter by Jules Pretty, the many ways that development organizations interpret and use the term participation are resolved into a typology of seven clear uses. These range from manipulative and passive participation, where people are told what is to happen and act out predetermined roles, to self-mobilization, where people take initiatives largely independent of external institutions. This suggests that new systems of learning are needed, using participatory methods and criteria for establishing trustworthiness. These have profound implications for agricultural professionals, who must now actively create a whole new professionalism.

Jan Douwe van der Ploeg has contributed a great deal to our understanding of the motivations and actions of farmers and their 'farming styles'. In this first chapter from *The Virtual Farmer*, he explores and takes forward the idea of a storylines framework, which interweaves and interconnects in particular places. These storylines are important to van der Ploeg. The first concerns agriculture as a complex practice, as a carefully coordinated effort to mobile resources, to convert these resources into end products, and then the sale of these end products. The second storyline concerns the heterogeneity of farming as an expression of a 'dance through time'. The third storyline is a systematic critique of various forms of determinism – technological, economic and structural. This opening chapter addresses past, present and future, in which actors create projects, and collaborate or compete. Time is important, as desired future outcomes reach back to the present to affect actors in different ways.

Integrated Pest Management has been increasingly spread to farmers of a wide variety of agricultural systems. Perhaps the most successful advances have occurred in the rice-based systems of Asia. This article by Marc Barzman and Sylvie Desilles describes the experience of CARE-Bangladesh over an eight-year period, which has raised agricultural productivity by diversifying agroecosystems, reducing the costs of production, and creating new income sources for small farmers. Some 150,000 farmers have been involved in the programme, which has emphasized five technologies: (1) sustainable agricultural practices in rice; (2) vegetable production on rice field dykes; (3) fish production inside the rice field; (4) production of fish fingerlings; and (5) tree planting on rice field dykes. The main institutional mechanism to promote change is the farmer field school, in which farmers are trained over the course of a season in new approaches, and during which they come to appreciate the value of experimentation and sharing of results amongst one another. The article documents the economic benefits of the programme, as well as the non-economic ones, which include better nutrition, improved environments, and empowerment of farmers and their communities. There remain difficulties, though, particularly in ensuring participation of the very poorest families, and the reorganization of agricultural services and suppliers to the new agroecological systems that have emerged.

In the final article, Madhav Gagdil, colleagues and members of the People's Biodiversity Initiative show how folk knowledge and wisdom can be maintained. Gadgil indicates that such folk knowledge is transmitted and augmented almost entirely in the course of applying it in practice, but as it generally lacks a formal institutionalized process, it is vulnerable to changing relationships between people and their ecological resource base. In developing countries like India, people have access to newer resources, but are at the same time losing control over local resources, with the state and corporate taking over local interests. The programme of the People's Biodiversity Registers (PBRs) is an attempt to create a new institutional content for the continued use and development of indigenous knowledge.

The article summarizes the experience of organizing the preparation of 52 PBRs across the major ecosystems of India. The entire programme engaged 350 researchers and 200 assistants from village communities. The research found consistent increases in agricultural, wood, fish and shrimp production, but outside managed agroecosystems, there has been a widespread decline in both productivity and diversity of living resources. They document the breakdown of localized authority and rules for resource management, and even the case of a village in Rajasthan that used to be called the village of the medicine men, Vaidyonki Devli, but had now been renamed Devli because of the severe depletion of medicinal plant resources in the locality. They also recorded a decline in ecological knowledge amongst young people, though with some exceptions, such as where youth are still involved in fishing as a profession. In only two of the cases had there been spontaneous establishment of new regimes of regulated use that had led to resource recovery.

Part III: Governance and Education

Cees Leeuwis' 2004 book *Communication for Rural Innovation* contains a clear and insightful update of agricultural extension theory and practice, and this article, chapter 2 from the book, addresses the shift from extension to communication for innovation. The challenges for extension are changing rapidly, as recognition of different conditions and cultures grows. This chapter focuses first on an historical overview of how extension has been seen in the past – primarily implying that something is passed from someone or some institution who knows to someone else who does not know. It seeks to extend, and those who do not adopt the progressive message or technology are commonly seen as laggards or backward. It is their fault that they have not changed their practices (even if they themselves have very good reason for rejection). Leeuwis proposes a novel definition for extension here, even though some writers have suggested the abandonment of the term altogether because of its unidirectional connotations. In practice, communication for innovation can take many forms, and these are discussed in detail, together with concepts of knowledge systems, extension education, extension research and extension science. A new definition for extension emerges from these debates.

The second paper by K. L. Heong and colleagues describes a rare discovery – a simple technology, in this case a practice, that can be spread widely amongst farmers that brings both economic and environmental benefits. The problem is that many rice farmers spray insecticides based on their perceptions of potential damage and losses caused by pests. Farmers generally overestimate the seriousness of leaf damage caused by a variety of leaf-feeding insects, and so start applying insecticides. Yet damage to the rice crop during the vegetative stage rarely affects yields, even if as much as 40 per cent of a leaf is consumed. Early applications of insecticide are therefore unnecessary. This paper describes the testing and spreading of a simple heuristic or rule of thumb to Vietnamese farmers in the Mekong Delta: 'Spraying insecticides for leaf folder control in the first 40 days after sowing is not needed.' A wide range of communication media were used to spread this simple message. Two and half years after the media introduction, insecticide sprays had fallen from 3.4 to 1.6 per season, saving farmers both insecticide and labour costs. The practice was then spread to 200,000 farmers in Long An, and then to the whole Mekong Delta of 2 million farmers.

The slow adoption of conservation farming systems in the uplands of the Philippines is the focus of the third paper by Rob Cramb and Z. Culasero. Agricultural degradation in the densely populated, steeply sloping regions has long been recognized as a major environmental problem, with significant on- and off-site impacts. A variety of effective conservation farming methods based on contour hedgerows of shrub legumes had been developed, yet sustained uptake by farmers was limited. This paper focuses on the potential of the landcare approach to develop new forms of collective action at the local levels. Landcare centres on the formation of community groups, supported by varying degrees through partnerships with government and non-government agencies. The paper specifically reports on the impacts of such an institution-building approach in southern Mindanao. The main effect of the programme was to enhance human capital through practical, farmer-led training and extension, enabling farmers to incorporate soil conservation and agroforestry technologies into their farming systems. The social capital formed, especially through the landcare associations, was critical to these outcomes. Strong partnerships will be required in future if such progress is to be sustained, and then spread to other communities.

Wendell Berry is one of the best known writers on agrarian pasts and presents in North America. He is a practising farmer, poet and author of many books. In this excerpt from his 1976 book, *The Unsettling of America*, he tells the story of the change in culture and agriculture in a few short generations of frontier invasion, spread and modernization. America was not settled, but unsettled, and it resulted in the exploitation of the land and its people. It ultimately, too, undermined the environmental security and health of the settlers. The production treadmill based on competition and degradation resulted in the loss of family farmers from the land – a process that has continued at a faster pace since the writing of this chapter in the 1970s. As he says, 'the care of the earth is our most ancient and most worthy and, after all, our most pleasing responsibility'. To cherish what remains of it, and to foster renewal, is our only legitimate hope.

Education in agroecology, agricultural systems and sustainable agriculture can provide students with a broad curriculum that deals with the interaction among production, economic, environmental and social dimensions of farming and food systems. Courses in agroecology and organic farming are now becoming more prevalent on university campuses in the Nordic region, Europe, US and elsewhere. Geir Lieblin and colleagues observe that in most programmes and courses the teaching methods have departed little from a strong emphasis on transmitting information through lectures, some discussion and library readings, and periodic trips to farms that often turn into lectures in the field. Adult education provides an appropriate set of methods for learning about the complexities of farming systems. Agroecology provides a new framework to organize learning opportunities for students interested in solving challenges in today's world. The authors' programmes in agroecology concentrate on discovery and learning. Rather than agroecological theory having primary value, they immerse students in practical phenomena at the farming and food system level, and let these phenomena determine what theory is necessary and relevant. Teachers are converted from lecturers to leaders and catalysts in the learning process.

Part IV: Enabling Policies and Institutions

The first chapter in Niels Roling and Annemarie Wagemakers' 1998 book *Facilitating Sustainable Agriculture* sets out a series of significant challenges for actors and institutions engaged with agricultural development and the sustainability project. Five interlocking dimensions are identified, including agricultural practices, learning these practices, facilitating that learning, institutional frameworks that support such facilitation, and conducive policy frameworks. Sustainability is seen as an emergent property of systems – the outcome of the collective decision making that arises from interaction among stakeholders. The formulation of sustainability in this manner implies that the definition is part of the problem that stakeholders have to resolve. This chapter describes the social energy required to make the flip, and explores the prevalent paradigm for thinking about innovation (which gets in the way of progress towards sustainability). Constructionism is the term given to the epistemology which supports learning processes described in this book. If everyone agrees about the goals, we can afford to worry about the best technological means of securing those goals. If everyone agrees about the facts, we can speak of objective truth. But these conditions rarely hold, and as reality is no longer a given, then it becomes something that has to be constructed by people.

John Kerr and colleagues address a pervasive problem in agricultural development. If farmers are paid to do something, such as adopt a new crop or build a terrace, then they are not likely to question the choice of technology, nor to adapt it to their own conditions. At the same time, external professionals are not challenged to ensure that technologies do indeed fit local conditions and needs. In this paper, the use of subsidies in watershed development in India is analysed. The authors do not argue that government support for agriculture and poverty alleviation should not be given. Rather, they show that some unintended negative consequences of heavy subsidies actually undermine watershed development objectives. The problem is that subsidies are used to achieve both watershed development and employment generation, a lot to ask of any policy intervention. The consequences on the ground can be severe – villagers may praise contour bunds for water conservation when in the presence of government officials, yet destroy them when they leave. Villagers also agree that they would happily engage in inappropriate soil and water conservation activities if these were a way to obtain additional employment. Kerr and colleagues suggest alternative ways to manage subsidies for watershed development.

The third paper by Thomas Dobbs and Jules Pretty is an analysis of the effectiveness of agrienvironmental schemes in the UK. Agriculture is now being seen more as a multifunctional activity – it does more than just produce food. The side effects, both positive and negative, have important implications on local and national ecological and social systems. This idea of multifunctionality is now being internalized into policies so that financial support can be used to encourage the flow of environmental goods and services from specific landscapes. The UK introduced the first agrienvironmental scheme in the European Union (EU) in 1986, and since then it has developed and implemented several other schemes that also feature stewardship payments to improve agriculture's environmental performance. In this article, lessons learned from the UK's various agrienvironmental programmes are identified. The paper examines three key sets of issues associated with possible major expansions of *stewardship payment* programmes. These issues concern: (1) the compatibility of production support and stewardship support; (2) balancing stewardship payments and environmental compliance; and (3) the compatibility of World Trade Organization rules with stewardship schemes. Using the concept of 'multifunctionality', which increasingly is influencing agricultural policy in Europe, the authors examine key issues associated with potential major expansions of stewardship payment schemes on both sides of the Atlantic.

Ian Scoones' 2001 book *Dynamics and Diversity* emphasizes throughout the importance of taking local context seriously. Some of the key findings include understanding how farmers classify their own soils, and also seek to improve them over time. Africa's farming systems are highly diverse, and this diversity is a key feature at all scales. It is important for farmers as it reduces the risk of crop failure. Farming systems are dynamic, and there is no single pathway being followed by farmers at one site. Farmers' management of soil nutrients depends on a range of socioeconomic factors, and data on nutrient balances shows how there is a mixed pattern of accumulation and depletion, depending on plots, farmers and locations. Finally, farmers have all been affected by recent policy changes. This is the specific context for this chapter by Ian Scoones and Camilla Toulmin. This diversity of agroecological settings demands a differentiated approach for intervention strategies and policy options. The technological choices are important, as they are highly contested in many circles. With respect to Ethiopia, Mali and Zimbabwe, a range of policies are discussed, including devolution and structural adjustment, credit, rural infrastructure, research and extension services, and land and tenure reform. The problem, though, is though a range of policies affect farm management of soil fertility, rarely has soil-fertility management been the main target of policies. A sustainable livelihoods approach to policy design is suggested as a way forward.

The final article in this volume is by Patricia Benjamin and colleagues and addresses social visions of future sustainable societies. The new globalized society is currently undergoing rapid political, economic and cultural change, and we are going to need clear social visions, or stories, to determine possible (and hopefully attainable) outcomes. Social sustainability, note the authors, does not mean the continuation of existing social structures, but rather the creation and maintenance of the conditions for creativity, empowerment, self-determination and self-actualization. The article reviews past efforts to understand visions for the future – a history of the future. Visions are stories of possible alternative futures, and the process of forming them may be viewed as a purposeful strategic choice. But discourses will need to be broad if visions are not to converge to a single model that could result in severe environmental destruction. Stories for divergence are required, and sustainable agricultural systems have a role to play in developing and maintaining such alternatives.

Part I

Ethics and Systems Thinking

1

The Land Ethic

A. Leopold

When god-like Odysseus returned from the wars in Troy, he hanged all on one rope a dozen slave-girls of his household whom he suspected of misbehaviour during his absence.

This hanging involved no question of propriety. The girls were property. The disposal of property was then, as now, a matter of expediency, not of right and wrong.

Concepts of right and wrong were not lacking from Odysseus' Greece: witness the fidelity of his wife through the long years before at last his black-prowed galleys clove the wine-dark seas for home. The ethical structure of that day covered wives, but had not yet been extended to human chattels. During the 3000 years which have since elapsed, ethical criteria have been extended to many fields of conduct, with corresponding shrinkages in those judged by expediency only.

This extension of ethics, so far studied only by philosophers, is actually a process in ecological evolution. Its sequences may be described in ecological as well as in philosophical terms. An ethic, ecologically, is a limitation on freedom of action in the struggle for existence. An ethic, philosophically, is a differentiation of social from antisocial conduct. These are two definitions of one thing. The thing has its origin in the tendency of interdependent individuals or groups to evolve modes of cooperation. The ecologist calls these symbioses. Politics and economics are advanced symbioses in which the original free-for-all competition has been replaced, in part, by cooperative mechanisms with an ethical content.

The complexity of cooperative mechanisms has increased with population density, and with the efficiency of tools. It was simpler, for example, to define the antisocial uses of sticks and stones in the days of the mastodons than of bullets and billboards in the age of motors.

The first ethics dealt with the relation between individuals; the Mosaic Decalogue is an example. Later accretions dealt with the relation between the individual and society. The Golden Rule tries to integrate the individual to society; democracy to integrate social organization to the individual.

Reprinted from Leopold A. 1949. The land ethic. In *A Sand Country Almanac and Sketches Here and There.* Oxford University Press, London. By permission of Oxford University Press, Inc.

There is as yet no ethic dealing with man's relation to land and to the animals and plants which grow upon it. Land, like Odysseus' slave-girls, is still property. The land-relation is still strictly economic, entailing privileges but not obligations.

The extension of ethics to this third element in human environment is, if I read the evidence correctly, an evolutionary possibility and an ecological necessity. It is the third step in a sequence. The first two have already been taken. Individual thinkers since the days of Ezekiel and Isaiah have asserted that the despoliation of land is not only inexpedient but wrong. Society, however, has not yet affirmed their belief. I regard the present conservation movement as the embryo of such an affirmation.

An ethic may be regarded as a mode of guidance for meeting ecological situations so new or intricate, or involving such deferred reactions, that the path of social expediency is not discernible to the average individual. Animal instincts are modes of guidance for the individual in meeting such situations. Ethics are possibly a kind of community instinct in-the-making.

The Community Concept

All ethics so far evolved rest upon a single premise: that the individual is a member of a community of interdependent parts. His instincts prompt him to compete for his place in the community, but his ethics prompt him also to cooperate (perhaps in order that there may be a place to compete for).

The land ethic simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively: the land.

This sounds simple: do we not already sing our love for and obligation to the land of the free and the home of the brave? Yes, but just what and whom do we love? Certainly not the soil, which we are sending helter-skelter downriver. Certainly not the waters, which we assume have no function except to turn turbines, float barges and carry off sewage. Certainly not the plants, of which we exterminate whole communities without batting an eye. Certainly not the animals, of which we have already extirpated many of the largest and most beautiful species. A land ethic of course cannot prevent the alteration, management and use of these 'resources,' but it does affirm their right to continued existence, and, at least in spots, their continued existence in a natural state.

In short, a land ethic changes the role of *Homo sapiens* from conqueror of the land-community to plain member and citizen of it. It implies respect for his fellow-members, and also respect for the community as such.

In human history, we have learned (I hope) that the conqueror role is eventually self-defeating. Why? Because it is implicit in such a role that the conqueror knows, *ex cathedra*, just what makes the community clock tick, and just what and who is valuable, and what and who is worthless, in community life. It always turns out that he knows neither, and this is why his conquests eventually defeat themselves.

In the biotic community, a parallel situation exists. Abraham knew exactly what the land was for: it was to drip milk and honey into Abraham's mouth. At the present moment, the assurance with which we regard this assumption is inverse to the degree of our education.

The ordinary citizen today assumes that science knows what makes the community clock tick; the scientist is equally sure that he does not. He knows that the biotic mechanism is so complex that its workings may never be fully understood.

That man is, in fact, only a member of a biotic team is shown by an ecological interpretation of history. Many historical events, hitherto explained solely in terms of human enterprise, were actually biotic interactions between people and land. The characteristics of the land determined the facts quite as potently as the characteristics of the men who lived on it.

Consider, for example, the settlement of the Mississippi valley. In the years following the Revolution, three groups were contending for its control: the native Indian, the French and English traders, and the American settlers. Historians wonder what would have happened if the English at Detroit had thrown a little more weight into the Indian side of those tipsy scales which decided the outcome of the colonial migration into the cane-lands of Kentucky. It is time now to ponder the fact that the cane-lands, when subjected to the particular mixture of forces represented by the cow, plough, fire and axe of the pioneer, became bluegrass. What if the plant succession inherent in this dark and bloody ground had, under the impact of these forces, given us some worthless sedge, shrub, or weed? Would Boone and Kenton have held out? Would there have been any overflow into Ohio, Indiana, Illinois and Missouri? Any Louisiana Purchase? Any transcontinental union of new states? Any Civil War?

Kentucky was one sentence in the drama of history. We are commonly told what the human actors in this drama tried to do, but we are seldom told that their success, or the lack of it, hung in large degree on the reaction of particular soils to the impact of the particular forces exerted by their occupancy. In the case of Kentucky, we do not even know where the bluegrass came from – whether it is a native species, or a stowaway from Europe.

Contrast the cane-lands with what hindsight tells us about the Southwest, where the pioneers were equally brave, resourceful and persevering. The impact of occupancy here brought no bluegrass, or other plant fitted to withstand the bumps and buffetings of hard use. This region, when grazed by livestock, reverted through a series of more and more worthless grasses, shrubs and weeds to a condition of unstable equilibrium. Each recession of plant types bred erosion; each increment to erosion bred a further recession of plants. The result today is a progressive and mutual deterioration, not only of plants and soils, but of the animal community subsisting thereon. The early settlers did not expect this: on the *ciénegas* of New Mexico some even cut ditches to hasten it. So subtle has been its progress that few residents of the region are aware of it. It is quite invisible to the tourist who finds this wrecked landscape colourful and charming (as indeed it is, but it bears scant resemblance to what it was in 1848).

This same landscape was 'developed' once before, but with quite different results. The Pueblo Indians settled the Southwest in pre-Columbian times, but they happened *not* to be equipped with range livestock. Their civilization expired, but not because their land expired.

In India, regions devoid of any sod-forming grass have been settled, apparently without wrecking the land, by the simple expedient of carrying the grass to the cow, rather than vice versa. (Was this the result of some deep wisdom, or was it just good luck? I do not know.)

In short, the plant succession steered the course of history; the pioneer simply demonstrated, for good or ill, what successions inhered in the land. Is history taught in this spirit? It will be, once the concept of land as a community really penetrates our intellectual life.

The Ecological Conscience

Conservation is a state of harmony between men and land. Despite nearly a century of propaganda, conservation still proceeds at a snail's pace; progress still consists largely of letterhead pieties and convention oratory. On the back forty we still slip two steps backward for each forward stride.

The usual answer to this dilemma is 'more conservation education'. No one will debate this, but is it certain that only the *volume* of education needs stepping up? Is something lacking in the *content* as well?

It is difficult to give a fair summary of its content in brief form, but, as I understand it, the content is substantially this: obey the law, vote right, join some organizations and practice what conservation is profitable on your own land; the government will do the rest.
